Information Builders

WebFOCUS

Adapter Administration

WebFOCUS Reporting Server Release 8206
DataMigrator Server Release 7710

January 30, 2020

Contents

Preface

This manual describes the configuration and management of Adapters. It is intended for database administrators and application developers.

How This Manual Is Organized

This manual includes the following chapters:

	Chapter/Appendix	Contents
1	Introduction to Adapters	Describes how to use adapters.
2	Using the Adapter for 1010data	Describes how to configure the Adapter for 1010data.
3	Using the Adapter for Adabas	Describes how to configure the Adapter for Adabas.
4	Using the Adapter for Adabas Stored Procedures	Describes how to configure the Adapter for Adabas Stored Procedures.
5	Using the Adapter for Alchemy Sentiment Analysis	Describes how to configure the Alchemy Sentiment Analysis Adapter.
6	Using the Adapter for Amazon Athena	Describes how to configure the adapter for Amazon Athena.
7	Using the Adapter for Amazon Redshift	Describes how to configure the Adapter for Amazon Redshift.
8	Using the Adapter for Apache Drill	Describes how to configure the adapter for Apache Drill.
9	Using the Adapter for Apache Hive to Access Data Managed by Hadoop	Describes how to configure the adapter for Hadoop with Apache Hive.
10	Using the Adapter for Apache Phoenix to Access HBase	Describes how to configure the adapter for Apache Phoenix to access HBase.
11	Using the Adapter for Apache Spark	Describes how to configure the Adapter for Apache Spark.
12	Using the Adapter for Axiom EPM	Describes how to configure the Adapter for Axiom EPM.

	Chapter/Appendix	Contents
13	Using the Adapter for C9 INC	Describes how to configure the Adapter for C9 INC.
14	Using the Adapter for Caché	Describes how to configure the Adapter for Caché.
15	Using the Adapter for CICS Transactions	Describes how to configure the Adapter for CICS Transactions.
16	Using the Adapter for Cloudera Impala to Access Data Managed by Hadoop	Describes how to configure the Adapter for Cloudera Impala.
17	Using the Adapters for C-ISAM and ISAM	Describes how to configure the Adapter for C-ISAM and ISAM.
18	Using the Adapter for DATACOM	Describes how to configure the Adapter for DATACOM.
19	Using the Adapter for Db2	Describes how to configure the Adapter for Db2.
20	Using the Adapter for DB Heritage Files	Describes how to configure the Adapter for DB Heritage Files.
21	Using the Adapter for Esri ArcGIS	Describes how to configure the adapter for Esri ArcGIS.
22	Using the Adapter for Essbase	Describes how to configure the Adapter for Essbase.
23	Using the Adapter for EXASol	Describes how to configure the adapter for EXASol.
24	Using the Adapter for Excel	Describes how to configure the Adapter for Excel.
25	Using the Adapter for Excel (via Direct Retrieval)	Describes how to configure the Adapter for Excel (via Direct Retrieval).
26	Using the Adapter for Facebook	Describes how to configure the Facebook Adapter.
27	Using the Adapters for Fixed-Format and Delimited Files	Describes how to configure the Adapter for Fixed-Format and Delimited Files.
28	Using the Adapter for Git	Describes how to configure the adapter for Git.

	Chapter/Appendix	Contents
29	Using the Adapter for Google Analytics	Describes how to configure the Google Analytics Adapter.
30	Using the Adapter for Google BigQuery	Describes how to configure the Google BigQuery Adapter.
31	Using the Adapter for Greenplum	Describes how to configure the Adapter for Greenplum.
32	Using the Adapter for HP Vertica	Describes how to configure the Adapter for HP Vertica.
33	Using the Adapter for Hyperledger Fabric	Describes how to configure and create synonyms for the adapter for Hyperledger Fabric.
34	Using the Adapter for Hyperstage	Describes how to configure the Adapter for Hyperstage.
35	Using the Adapter for i Access	Describes how to configure the Adapter for ODBC.
36	Using the Adapter for CA-IDMS/DB	Describes how to configure the Adapter for CA-IDMS/DB.
37	Using the Adapter for CA-IDMS/SQL	Describes how to configure the Adapter for CA-IDMS/SQL.
38	Using the Adapter for IMS	Describes how to configure and use the Adapter for IMS
39	Using the Adapter for IMS Transactions	Describes how to configure the Adapter for IMS Transactions.
40	Using the Adapter for Informix	Describes how to configure the Adapter for Informix.
41	Using the Adapter for Ingres	Describes how to configure the Adapter for Ingres.
42	Using the Adapter for Interplex	Describes how to configure the Adapter for Interplex.
43	Using the Adapter for iWay Adapter Framework (IWAF)	Describes how to configure the Adapter for iWay Adapter Framework (IWAF).

	Chapter/Appendix	Contents
44	Using the Adapter for JBoss Application Server	Describes how to configure the Adapter for JBoss Application Server.
45	Using the Adapter for JDBC	Describes how to configure the Adapter for JDBC.
46	Using the Adapter for JD Edwards EnterpriseOne	Describes how to configure the Adapter for JD Edwards EnterpriseOne.
47	Using the Adapter for JD Edwards World	Describes how to configure the Adapter for JD Edwards World.
48	Using the Adapter for Jethro	Describes how to configure the Adapter for Jethro.
49	Using the Adapter for JSON	Describes how to configure the Adapter for JSON.
50	Using the Adapter for Kafka	Describes how to configure the Adapter for Kafka.
51	Using the Adapter for Lawson	Describes how to configure the Adapter for Lawson.
52	Using the Adapter for LinkedIn	Describes how to configure the LinkedIn Adapter.
53	Using the Adapter for Lotus Notes	Describes how to configure the Adapter for Lotus Notes.
54	Using the Adapter for LDAP	Describes how to configure the Adapter for LDAP.
55	Using the Adapter for MariaDB	Describes how to configure the Adapter for MariaDB.
56	Using the Adapter for Microsoft Access	Describes how to configure the Adapter for Microsoft Access.
57	Using the Adapter for Microsoft Azure SQL Data Warehouse	Describes how to configure the Adapter for Microsoft Azure SQL Data Warehouse.
58	Using the Adapter for Microsoft Dynamics CRM	Describes how to configure the Adapter for Microsoft Dynamics CRM
59	Using the Adapter for Microsoft SQL Server	Describes how to configure the Adapter for Microsoft SQL Server.

	Chapter/Appendix	Contents
60	Using the Adapter for Microsoft SQL Server Analysis Services (SSAS)	Describes how to configure the Adapter for SQL Server Analysis Services (SSAS).
61	Using the Adapter for Microsoft SQL Server Analysis Services Tabular Data Model	Describes how to configure the Adapter for Microsoft SQL Server Analysis Services Tabular Data Model.
62	Using the Adapter for Microsoft SQL Server ODBC	Describes how to configure the Adapter for Microsoft SQL Server ODBC.
63	Using the Adapter for Millennium	Describes how to configure the Adapter for Millennium.
64	Using the Adapter for Model 204	Describes how to configure the Adapter for Model 204.
65	Using the Adapter for MongoDB	Describes how to configure the adapter for MongoDB.
66	Using the Adapter for MySQL	Describes how to configure the Adapter for MySQL.
67	Using the Adapter for NATURAL	Describes how to configure the Adapter for NATURAL.
68	Using the Adapter for NATURAL CICS Transactions	Describes how to configure the Adapter for NATURAL CICS Transactions.
69	Using the Adapter for Netezza	Describes how to configure the Adapter for Netezza.
70	Using the Adapter for Nucleus	Describes how to configure the Adapter for Nucleus.
71	Using the Adapter for OData	Describes how to configure the Adapter for OData.
72	Using the Adapter for ODBC	Describes how to configure the Adapter for ODBC.
73	Using the Adapter for Oracle	Describes how to configure the Adapter for Oracle.
74	Using the Adapter for Oracle E-Business Suite	Describes how to configure the Adapter for Oracle E-Business Suite.

	Chapter/Appendix	Contents
75	Using the Adapter for Oracle TimesTen	Describes how to configure the Adapter for Oracle TimesTen.
76	Using the Adapter for parAccel	Describes how to configure the Adapter for parAccel.
77	Using the Adapter for PeopleSoft	Describes how to configure the Adapter for PeopleSoft.
78	Using the Adapter for PostgreSQL	Describes how to configure the Adapter for PostgreSQL.
79	Using the Adapter for Presto	Describes how to configure the Adapter for Presto
80	Using the Adapter for Progress	Describes how to configure the Adapter for Progress.
81	Using the Adapter for PSQL	Describes how to configure the Adapter for PSQL.
82	Using the Adapter for Python	Describes how to configure the adapter and run Python scripts.
83	Using the Adapter for Query/400	Describes how to configure the Adapter for Query/400.
84	Using the Adapter for Rdb	Describes how to configure the Adapter for Rdb.
85	Using the Adapter for Remote Servers	Describes how to configure the Adapter for Remote Servers.
86	Using the Adapter for REST	Describes how to configure the Adapter for REST.
87	Using the Adapter for RMS	Describes how to configure the Adapter for RMS.
88	Using the Adapter for Rserve	Describes how to configure the adapter, create a synonym for an R script, and run the script using the RSERVE function.
89	Using the Adapter for Salesforce.com	Describes how to configure the Adapter for Salesforce.com.

	Chapter/Appendix	Contents
90	Using the Adapter for SAP Business Intelligence Warehouse (BW)	Describes how to configure the Adapter for SAP Business Intelligence Warehouse (BW).
91	Using the Adapter for SAP ERP	Describes how to configure the Adapter for SAP.
92	Using the Adapter for SAP Hana	Describes how to configure the Adapter for SAP Hana.
93	Using the Adapter for Siebel	Describes how to configure the Adapter for Siebel.
94	Using the Adapter for Slack	Describes how to configure the Adapter for Slack.
95	Using the Adapter for Snowflake Cloud Data Warehouse	Describes how to configure the Adapter for Snowflake Cloud Data Warehouse
96	Using the Adapter for SQLBase	Describes how to configure the Adapter for SQLBase.
97	Using the Adapter for Stratio Crossdata	Describes how to configure the Adapter for Stratio Crossdata.
98	Using the Adapter for Supra	Describes how to configure the Adapter for Supra
99	Using the Adapter for Sybase	Describes how to configure the Adapter for Sybase.
100	Using the Adapter for Teradata	Describes how to configure the Adapter for Teradata.
101	Using the Adapter for Transoft	Describes how to configure the Adapter for Transoft.
102	Using the Adapter for Twitter	Describes how to configure the Twitter Adapter.
103	Using the Adapter for UniData	Describes how to configure the Adapter for UniData.
104	Using the Adapter for UniVerse	Describes how to configure the Adapter for UniVerse.
105	Using the Adapter for VSAM	Describes how to configure the Adapter for VSAM.

	Chapter/Appendix	Contents
106	Using the Adapter for WAND Sentiment Analysis	Describes how to configure the WAND Sentiment Analysis Adapter.
107	Using the Adapter for Web Services	Describes how to configure the Adapter for Web Services.
108	Using the Adapter for WebFOCUS Client REST	
109	Using the Adapter for Words Analysis	Describes how to configure the Words Analysis Adapter.
110	Using the Adapter for XML	Describes how to configure the Adapter for XML.
A	XA Support	Describes XA Transaction Management and implementation specifics.
B	Aggregate Awareness Support	Describes Aggregate Awareness, which substantially improves the efficiency of queries.
C	Cluster Join	Describes the Master File SEGSUF attribute, which enables you to create heterogeneous cluster joins.
D	Translating COBOL File Descriptions	Describes how synonyms are created from COBOL File Descriptions.
E	Data Set Compression Exit: ZCOMP	Describes how to use the ZCOMP Exit for data set compression.
F	Dynamic Private User Exit	Describes how use the Dynamic Private User Exit API.
G	Validation for Special Characters and Reserved Words	Describes how the Web Console validates special characters and reserved words.

Conventions

The following conventions apply throughout this manual:

Convention	Description

`THIS TYPEFACE`
or
`this typeface`
	Denotes syntax that you must enter exactly as shown.

`this typeface`	Represents a placeholder (or variable) in syntax for a value that you or the system must supply.
`underscore`	Indicates a default setting.
this typeface	Represents a placeholder (or variable), a cross-reference, or an important term. It may also indicate a button, menu item, or dialog box option that you can click or select.
Key + Key	Indicates keys that you must press simultaneously.
`{ }`	Indicates two or three choices. Type one of them, not the braces.
`[ ]`	Indicates a group of optional parameters. None are required, but you may select one of them. Type only the parameter in the brackets, not the brackets.
`|`	Separates mutually exclusive choices in syntax. Type one of them, not the symbol.
`...`	Indicates that you can enter a parameter multiple times. Type only the parameter, not the ellipsis (...).
. . .	Indicates that there are (or could be) intervening or additional commands.

Customer Support

Do you have any questions about this product?

Join the Focal Point community. Focal Point is our online developer center and more than a message board. It is an interactive network of more than 3,000 developers from almost every profession and industry, collaborating on solutions and sharing tips and techniques, *http://forums.informationbuilders.com/eve/forums*.

You can also access support services electronically, 24 hours a day, with InfoResponse Online. InfoResponse Online is accessible through our website, *http://www.informationbuilders.com*. It connects you to the tracking system and known-problem database at the Information Builders support center. Registered users can open, update, and view the status of cases in the tracking system and read descriptions of reported software issues. New users can register immediately for this service. The technical support section of www.informationbuilders.com also provides usage techniques, diagnostic tips, and answers to frequently asked questions.

Call Information Builders Customer Support Service (CSS) at (800) 736-6130 or (212) 736-6130. Customer Support Consultants are available Monday through Friday between 8:00 a.m. and 8:00 p.m. EST to address all your questions. Information Builders consultants can also give you general guidance regarding product capabilities. Please be ready to provide your six-digit site code number (*xxxx.xx*) when you call.

To learn about the full range of available support services, ask your Information Builders representative about InfoResponse Online, or call (800) 969-INFO.

Information You Should Have

To help our consultants answer your questions most effectively, be ready to provide the following information when you call:

- ❏ Your six-digit site code (*xxxx.xx*).
- ❏ Your Server Software configuration:
  - ❏ The version and release. You can find your server version and release using the *Version* option in the Web Console.
  - ❏ The communications protocol (for example, TCP/IP), including vendor and release.
- ❏ The stored procedure (preferably with line numbers) or SQL statements being used in server access.
- ❏ The database server release level.

- The database name and release level.
- The Master File and Access File.
- The exact nature of the problem:
  - Are the results or the format incorrect? Are the text or calculations missing or misplaced?
  - The error message and return code, if applicable.
  - Is this related to any other problem?
- Has the procedure or query ever worked in its present form? Has it been changed recently? How often does the problem occur?
- What release of the operating system are you using? Has it, your security system, communications protocol, or front-end software changed?
- Is this problem reproducible? If so, how?
- Have you tried to reproduce your problem in the simplest form possible? For example, if you are having problems joining two data sources, have you tried executing a query containing just the code to access the data source?
- Do you have a trace file?
- How is the problem affecting your business? Is it halting development or production? Do you just have questions about functionality or documentation?

User Feedback

In an effort to produce effective documentation, the Technical Content Management staff welcomes your opinions regarding this document. You can contact us through our website *http://documentation.informationbuilders.com/connections.asp*.

Thank you, in advance, for your comments.

Information Builders Training and Professional Services

Interested in training? Our Education Department offers a wide variety of training courses for this and other Information Builders products.

For information on course descriptions, locations, and dates, or to register for classes, visit our website (*http://education.informationbuilders.com*) or call (800) 969-INFO to speak to an Education Representative.

Chapter 1

Introduction to Adapters

In client/server architecture, adapters enable clients to manage data from virtually any data source, and on any operating system, through the use of SQL statements.

The client generates requests for data residing on the server. The server acts as a source of data, and can accept requests from multiple clients for data access and manipulation. Client/server architecture divides a traditional single system into a front-end and a back-end. The workload is distributed between the client and the server. Communications software establishes the link between client and server, and interfaces to the desired communications protocol.

In this chapter:

Processing Requests

The server can process SQL requests. This enables it to support a wide variety of client applications that use SQL and for those clients, SQL is the standard access language for requests to all relational and non-relational data.

In addition, the server has its own 4-GL request language called WebFOCUS that provides a much more robust set of features than SQL and extends the types of requests that can be processed, especially requests against non-relational data sources whose architecture is not based on the relational model.

The server in client/server architecture is used for data access and manipulation. The server receives a request for data, processes it, and returns an answer set or message to the client. Adapters are among the various subsystems that comprise a server.

Functions of an Adapter

The server uses adapters to access data sources. The server can receive two types of requests from the client: SQL or WebFOCUS.

When the server receives requests from the client, it passes them to the adapter in a standard format. The adapter takes the request, transforms it into the native data manipulation language (DML), and then issues calls to the data source using its API. In this way, the adapter insulates the server from details of the data source. An application can issue SQL statements, issue WebFOCUS commands, or call stored procedures.

Adapters are available for many data sources. Every adapter is specifically designed for the data source that it accesses, and, as a result, is able to translate between SQL or WebFOCUS and the DML of the data source. Adapters provide solutions to product variations, including product differences in syntax, functionality, schema, data types, catalogs, data representations, message processing, and answer set retrieval.

Note: If the adapter has read/write capabilities, it inserts the data from an application to the data source.

How an Adapter Works

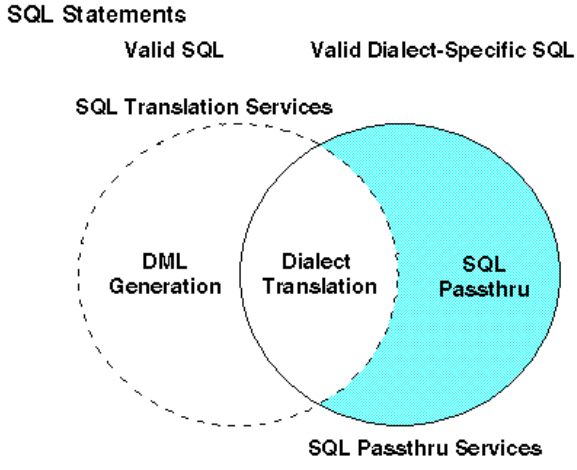
The adapter manages the communication between the data interface and the data source, passing data management requests to the data source and returning either answer sets or messages to the requestor.

To perform these functions, the adapter:

1. Translates the request to the applicable DML.
2. Attaches to the targeted data source, using standard attachment calls. The adapter then passes the request to the data source.
3. The data source processes the request.
4. The results or error conditions are returned to the client application for further processing.

Processing SQL Requests

A server can be configured to behave in different ways upon receipt of SQL requests from a client application. A server handles SQL requests for data in the following ways, as illustrated in the diagram:



- **Direct Passthru.** When Direct Passthru is enabled, the server passes SQL requests directly to the specified RDBMS for processing. The name of the targeted RDBMS (the database engine) is supplied in the server profile or, in some cases, by the client application. A Full-Function or Hub Server can operate temporarily in Direct Passthru mode when invoked by a client application. The user is responsible for activating and deactivating Direct Passthru as needed.
- **SQL Processing.** When the database engine is not set in the server profile or supplied by a client application, Direct Passthru is not enabled. Instead, a Hub or Full-Function Server invokes its default behavior: it accepts the incoming SQL request and verifies that it is valid. Then the server determines if it can process the incoming SQL request:
  - If the request meets certain requirements, the server passes it directly to the RDBMS for processing. This is called Automatic Passthru.
  - If the syntax of the request does not conform to the syntax of the RDBMS, the server translates the request into internal DML and passes it to the adapter. The adapter generates adapter-specific DML and passes the request to the RDBMS for processing. This is called SQL translation.

Processing WebFOCUS Requests

When the server receives a WebFOCUS request, it passes it to the adapter. The adapter analyzes the request and generates DBMS-specific DML for those parts of the request that have DML equivalents. As WebFOCUS is a more robust language than DML, some parts of the request may not have such equivalents. The adapter then passes the generated DML to the DBMS for processing. When the answer set is returned by the DBMS, WebFOCUS processes those parts of the request that the adapter could not pass to the DBMS.

Throughout this manual there are descriptions of some useful features that are not supported by SQL syntax but are supported by WebFOCUS syntax.

For complete information about the WebFOCUS language, see the following manuals:

- *Creating Reports With WebFOCUS Language*
- *Describing Data With WebFOCUS Language*
- *Developing Reporting Applications*

Relational and Non-Relational Adapters

Adapters can retrieve answer sets from both relational and non-relational data sources. Since the architectures of relational and non-relational data structures vary, the relational and non-relational adapters adjust for these differences. For example, relational adapters are designed to handle data sources that contain data in rows and columns in tables, while non-relational adapters are designed to accommodate the architecture of each distinct data source, for instance, a hierarchical or network data source, or a sequential or indexed file system.

The following table lists key features of relational and non-relational adapters:

Feature	Relational Adapters	Non-Relational Adapters
DEFINE (virtual field) in Master File	Yes	Yes
Access Control	Yes	Yes
Transaction Management Commands	Yes	No

Relational and non-relational adapters:

- Allow the data source to perform the work required to join, sort, and aggregate data. Therefore, the volume of data source-to-server communication is reduced, resulting in better response times for users. The adapter tries to optimize the queries as best it can.

- Communicate with the data source through DML statements. You can view these DML statements with traces provided by the trace facilities. These traces are helpful for debugging your procedure or for adapter performance analysis. Note that traces:
  - Are common for all relational adapters.
  - Vary for non-relational adapters to accommodate the differences in data structures and DML calls.
- Support both DEFINE (virtual) fields and DBA.
- Relational adapters include a variety of COMMIT, connection, and thread control commands that enable Database Administrators to control the opening and closing of connections and choose when to commit or rollback transactions. This level of transaction control is not supported by non-relational adapters. In Full-Function Server mode, COMMIT/ROLLBACK will be propagated to all relational data sources local to the server. If the hub is active, a COMMIT will be issued against remote data servers as well. All PREPARE handles are cleared (this is a Broadcast COMMIT).

To address these similarities and differences, this manual contains:

- *General* components with information that is common to all adapters, as well as information that is common either to all relational or to all non-relational adapters.
- *Customized* components with information that applies to specific adapters.

Supported Adapters

For the most current and specific information about releases and platforms,

1. Go to *http://techsupport.informationbuilders.com*.

   The Information Builders Technical Support home page opens.

2. In the Quick Links section on the right side of the page, click *Supported Systems/Adapters*.

   The Supported Systems and Adapters page opens.

3. Click the link for the server release you want.

   The Supported Systems and Adapters page for that release opens.

4. Click the link for your platform.

   The support chart for that platform opens.

The following table summarizes that information.

Adapter	Windows	UNIX	z/OS	OpenVMS	IBM i (formerly i5/OS)
1010data	x	x			
Adabas	x	x	x		
Adabas Stored Procedures			x		
Address Doctor	x	x	x	x	x
Alchemy	x	x	x	x	x
Business Object Universe	x	x	x	x	x

XML	x	x	x	x	x

* The underlying databases for these adapters do not necessarily run directly on the IBM i platform (formerly known as i5/OS). However, they may be configured and accessed.

Data Management

As you manage your data, you may be required to modify your server and communications configuration files. The first step is understanding how and where data is described and the roles of the server and adapters in managing the processing flow.

Describing Data Sources

In order to access a table or view, you must first describe it using two files: a Master File and an associated Access File.

Master Files and Access Files can represent an entire table or part of a table. Also, several pairs of Master and Access Files can define different subsets of columns for the same table, or one pair of Master and Access Files can describe several tables.

Note: In these topics, the term table refers to both base tables and views in data sources. The Master File describes the columns of the data source table using keywords in comma-delimited format. The Access File includes additional parameters that complete the definition of the data source table. Some adapters require both files to fulfill queries, and to build the DML to access the non-SQL data sources.

Processing Requests

When requests are processed, control is passed from the server to an adapter and back. During the process, selected information is read from the Master and Access Files as described below.

The server processes a request as follows:

1. The request is parsed to identify the table.
2. The Master File for the table is read.
3. The SUFFIX value in the Master File is checked (SUFFIX indicates the type of data source).
4. Control is passed to the appropriate adapter.

The adapter then:

1. Locates the corresponding Access File.
2. Uses the information contained in the Master and Access Files to generate the DML statements (if necessary) required to accomplish the request.
3. Passes the DML statements to the data source.
4. Retrieves the answer set generated by the data source.
5. Returns control to the server.

Depending on the requirements of the request, additional processing may be performed on the returned data.

Master File

A Master File describes a logical data source. A logical data source can be made up of one or more physical data sources of the same type. Each segment is a physical data source.

Master Files contain three types of declarations:

Declaration Type	Description
File	Names the file and describes the type of data source.
Segment	Identifies a table, file, view, or segment.
Field	Describes the columns of the table, view, or fields in the file.

The following guidelines apply:

- A declaration consists of attribute-value pairs separated by commas.
- Each declaration must begin on a separate line. A declaration can span as many lines as necessary, as long as no single keyword-value pair spans two lines.
- Do not use system or reserved words as names for files, segments, fields, or aliases. Specifying a reserved word generates syntax errors.

Syntax: How to Specify a File Declaration in a Master File

A Master File begins with a file declaration, which has at least two attributes:

`FILENAME (FILE)`

Identifies the Master File.

`SUFFIX`

Identifies the adapter needed to interpret the request.

The syntax for a file declaration is

`FILE[NAME]=`*`file`*`, SUFFIX=`*`suffix`* `[,$]`

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters.

suffix

Identifies the adapter needed to interpret the request. For example, SQLORA is the value for the Adapter for Oracle.

Syntax: How to Specify a Segment Declaration in a Master File

Each table described in a Master File requires a segment declaration. The segment declaration consists of at least two attributes:

SEGNAME

Identifies one table.

SEGTYPE

Identifies the physical storage of rows and the uniqueness of column values.

The syntax for a segment declaration is

```
SEGNAME=segname, SEGTYPE=S0 [,$]
```

where:

segname

Is the segment name which serves as a link to the actual table name. It may be the same as the name chosen for FILENAME, the actual table name, or an arbitrary name. It can consist of a maximum of 8 alphanumeric characters.

The SEGNAME value in the Master File must be the same as the SEGNAME value specified in the Access File, where the TABLENAME portion of the segment declaration contains the fully-qualified name of the table.

S0

Indicates that the RDBMS is responsible for both physical storage of rows and the uniqueness of column values (if a unique index or constraint exists). It always has a value of S0 (S zero).

Syntax: **How to Specify a Field Declaration in a Master File**

Each row in a table may consist of one or more columns. These columns are described in the Master File as fields with the following primary field attributes:

`FIELDNAME`

Identifies the name of a field.

`ALIAS`

Identifies the full column name.

`USAGE`

Identifies how to display a field on reports.

`ACTUAL`

Identifies the data type and length in bytes for a field.

`MISSING`

Identifies whether a field supports null data.

You can obtain values for these attributes by using the system catalog table ALL_TAB_COLUMNS for the existing table or view you wish to describe.

The syntax for a field declaration is

```
FIELD[NAME]=fieldname, [ALIAS=]sqlcolumn, [USAGE=]display_format,
     [ACTUAL=]storage_format [,MISSING={ON|OFF}], $
```

where:

fieldname

Is the name of the field. This value must be unique within the Master File. The name can consist of a maximum of 48 alphanumeric characters including letters, digits, and underscores. The name must begin with a letter. Special characters and embedded blanks are not recommended. The order of field declarations in the Master File is significant with regard to the specification of key columns. For more information, see *Primary Key* on page 88.

Tip: Since the name appears as the default column title for reports, for client applications, or EDADESCRIBE, select a name that is representative of the data.

It is not necessary to describe all the columns of the table in your Master File.

sqlcolumn

Is the full column name (the adapter uses it to generate SQL statements). This value must comply with the naming conventions for identifiers, where a name should start with a letter and may be followed by any combination of letters, digits, or underscores. Embedded spaces are not allowed.

display_format

Is the display format. The value must include the field type and length and may contain edit options.

The data type of the display format must be identical to that of the ACTUAL format. For example, a field with an alphanumeric USAGE data type must have an alphanumeric ACTUAL data type.

Fields or columns with decimal or floating point data types must be described with the correct scale (s) and precision (p). Scale is the number of positions to the right of the decimal point. Precision is the total length of the field.

For the server, the total display length of the field or column *includes* the decimal point and negative sign. In SQL, the total length of the field or column *excludes* the decimal point and negative sign. For example, a column defined as DECIMAL(5,2) would have a USAGE attribute of P7.2 to allow for the decimal point and a possible negative sign.

storage_format

Is the storage format of the data type and length in bytes.

ON

Displays the character specified by the NODATA parameter for missing data. For related information, see *MISSING Attribute* on page 86.

OFF

Displays blanks or zeroes for fields having no value. This is the default. For more information, see *MISSING Attribute* on page 86.

MISSING Attribute

In a table, a null value represents a missing or unknown value; it is not the same as a blank or a zero. For example, a column specification that allows null values is used where a column need not have a value in every row (such as a raise amount in a table containing payroll data).

- The default NODATA character is a period.
- A column in a table that allows null data does not need to include the NULL clause in its table definition, since that is the default.

- In the Master File for that table, the column that allows null data must be described with the MISSING attribute value ON. The default for this attribute is OFF, which corresponds to the NOT NULL attribute in the table definition.

If the column allows null data but the corresponding field in the Master File is described with the MISSING attribute value OFF, null data values appear as zeroes or blanks.

Access File

Each Master File may have a corresponding Access File. The name of the Access File must be identical to that of the Master File, but the extension will be .acx instead of .mas.

The Access File serves as a link between the server and the data source by providing the means to associate a segment in the Master File with the table it describes. The Access File minimally identifies the table and primary key (if there is one). It may also indicate the logical sort order of data and identify storage areas for the table.

Syntax: How to Specify a Segment Declaration in an Access File

The segment declaration in the Access File establishes the link between one segment of the Master File and the actual table or view. Attributes that constitute the segment declaration are:

`SEGNAME`

Identifies one table.

`TABLENAME`

Identifies the table or view. It may contain the owner ID as well as the table name.

`KEYS`

Identifies how many columns constitute the primary key.

`KEYORDER`

Identifies the logical sort sequence of data by the primary key.

The syntax for a segment declaration in an Access File is

```
SEGNAME=segname, TABLENAME=owner.tablename databaselink
   [,KEYS={n|0}] [,KEYORDER={LOW|HIGH}] ,$
```

where:

segname

Is the same value as the SEGNAME value in the Master File.

owner

Is the user ID by default.

tablename

Is the name of the table or view.

databaselink

Is the DATABASE LINK name to be used in the currently connected database server.

n

Is the number of columns that constitute the primary key. It can be a value from 0 to 16. The default value is 0. For more information, see *Primary Key* on page 88.

LOW

Indicates an ascending primary key logical sort order. This value is the default.

HIGH

Indicates a descending primary key logical sort order.

Primary Key

A primary key consists of the column or combination of columns whose values uniquely identify each row of the table. In the employee table, for example, every employee is assigned a unique employee identification number. Each employee is represented by one and only one row of the table, and is uniquely identified by that identification number.

The primary key definition must be defined partly in the Master File and partly in the Access File:

- The order of field declarations in the Master File is significant to the specification of key columns. To define the primary key in a Master File, describe its component fields immediately after the segment declaration. You can specify the remaining fields in any order. In the Access File, the KEYS attribute completes the process of defining the primary key.
- To identify the primary key, the adapter uses the number of columns (*n*) indicated by the KEYS attribute in the Access File and the first *n* fields described in the Master File.

Typically, the primary key is supported by the creation of a unique index in the SQL language to prevent the insertion of duplicate key values. The adapter itself does not require any index on the column(s) comprising the primary key (although a unique index is certainly desirable for both data integrity and performance reasons).

Creating Virtual Fields

You use the DEFINE command to accomplish these tasks.

Syntax: How to Create Virtual Fields With the DEFINE Command

```
DEFINE fieldname/format [WITH fieldname]=expression ;$
```

where:

fieldname

Is a field name for the virtual field. It can consist of 1 to 48 characters. You must not qualify the field name.

format

Provides the display format for the field and follows the rules for USAGE formats. This operand is optional. If not specified, the default value is D12.2.

WITH *fieldname*

Must be coded when the expression is a constant. Any real field can be chosen from the same segment the DEFINE is associated with.

expression

Can be either a mathematical or a logical statement. It can consist of constants, database fields, and virtual fields. The expression must end with a semicolon followed by a dollar sign (;$).

Place your DEFINE statements after all of the field descriptions in the segment. If you are using the DESCRIPTION or TITLE attributes with virtual fields, you must place these attributes on a separate line.

Example: Defining a Virtual Field in a Master File

In the example that follows, the virtual field PROFIT is defined at the end of the segment named BODY.

```
SEGMENT=BODY, SEGTYPE=S0 , PARENT=CARREC,$
 FIELDNAME=BODYTYPE          ,ALIAS=BODYTYPE      ,A12,A12,$
FIELDNAME=DEALER_COST        ,ALIAS=DEALER_COST   ,D8, D8 ,$
FIELDNAME=RETAIL_COST        ,ALIAS=RETAIL_COST   ,D8, D8 ,$
DEFINE PROFIT/D8 = RETAIL_COST - DEALER_COST
 ;DESC=NET_COST, TITLE='NET,COST' ,$
```

As a result of this DEFINE statement, you can use PROFIT as a field name in reports. PROFIT is treated as a field with a value equal to the value of RETAIL_COST minus DEALER_COST.

Note:

- Since the complete data source needs to be read to calculate virtual fields, screening conditions on virtual fields may incur additional overhead.
- Virtual fields in the Master File for relational and remote data sources will, if referenced in a query, disable Automatic Passthru.

Cross-Century Dates

Many existing business applications use two digits to designate a year, instead of four digits. When they receive a value for a year, such as 00, they typically interpret it as 1900, assuming that the first two digits are 19, for the twentieth century. There is considerable risk that date-sensitive calculations in existing applications will be wrong unless an apparatus is provided for determining the century in question. This will impact almost every type of application, including those that process mortgages, insurance policies, anniversaries, bonds, inventory replenishment, contracts, leases, pensions, receivables, and customer records.

The cross-century dates feature enables you to solve this problem at the file and field level of your applications. You can retain your global settings while changing the file-level settings for greater flexibility.

You can enable this feature:

- Using SET commands.
- At the file level in a Master File.
- At the field level in a Master File.

Cross-Century Dates SET Commands

The server delivers SET commands that provide a means of interpreting the century if the first two digits of the year are not provided:

```
SET DEFCENT
SET YRTHRESH
```

If the first two digits are provided, they are simply accepted and validated.

Syntax: How to Implement a Cross-Century Date

The DEFCENT syntax is

```
SET DEFCENT=nn
```

where:

nn

Is 19 unless otherwise specified.

The YRTHRESH syntax is

```
SET YRTHRESH=nn
```

where:

nn

Is zero unless otherwise specified.

The combination of DEFCENT and YRTHRESH establishes a base year for a 100-year window. Any 2-digit year is assumed to fall within that window, and the first two digits are set accordingly. Years outside the declared window must be handled by user coding.

The default values for the two commands are SET DEFCENT=19, SET YRTHRESH=00. When you provide a year threshold, years greater than or equal to that value assume the value assigned by DEFCENT. Years lower than that threshold become DEFCENT plus 1.

To see how DEFCENT and YRTHRESH are applied to interpret 2-digit years, consider the following:

```
SET DEFCENT=19, SET YRTHRESH=80
```

This set of commands describes a range from 1980 to 2079. If a 2-digit year field contains the value 99, then the server interprets the year as 1999. If the year field is 79, then the year is interpreted as 2079. If the year field is 00, then the year is interpreted as 2000.

Master File Syntax

Instead of using SET commands, you can include settings at the file level in a Master File, or at the field level in a Master File.

Syntax: How to Add Cross-Century Date Settings at the File Level

The FDEFCENT syntax is

```
{FDEFCENT|FDFC}=nn
```

where:

nn

Is 19, unless otherwise specified.

The FYRTHRESH syntax is

```
{FYRTHRESH|FYRT}=nn
```

where:

nn

Is zero, unless otherwise specified.

Syntax: How to Add Cross-Century Date Settings at the Field Level

At the field level, DEFCENT and YRTHRESH can be added. The DEFCENT syntax is

```
{DEFCENT|DFC}=nn
```

where:

nn

Is 19, unless otherwise specified.

The YRTHRESH syntax is

```
{YRTHRESH|YRT}=nn
```

where:

nn

Is zero, unless otherwise specified.

Syntax: How to Add Cross-Century Dates Using a DEFINE Command

```
DEFINE FILE EMPLOYEE
 fld/fmt [{DEFCENT|DFC} nn {YRTHRESH|YRT} nn] [MISSING...]=expression;
END
```

The DFC and YRT syntax must follow the field format information.

Example: Implementing Cross-Century Dates

The following example illustrates how century interpretation is implemented at both the file level and field level in a Master File.

```
FILENAME=EMPLOYEE, SUFFIX=FOC, FDEFCENT=20, FYRTHRESH=66,$
 SEGNAME=EMPINFO,  SEGTYPE=S1
  FIELDNAME=EMP_ID,     ALIAS=EID,  FORMAT=A9,       $
  FIELDNAME=LAST_NAME,  ALIAS=LN,   FORMAT=A15,      $
  FIELDNAME=FIRST_NAME, ALIAS=FN,   FORMAT=A10,      $
  FIELDNAME=HIRE_DATE,  ALIAS=HDT,  FORMAT=I6YMD, DEFCENT=19,
YRTHRESH=75,$
```

The next example illustrates the conversion of a 2-digit year field with the DEFINE command:

```
DEFINE FILE EMPLOYEE
ESHIRE_DATE/YYMD = HIRE_DATE; (The format of HIRE_DATE is I6YM.)
ESHIRE DFC 19 YRT 80 = HIRE_DATE;
END
```

Reference: **Synonym Management Options**

You can right-click a synonym in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

Option	Description
Open	Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.
Edit as Text	Enables you to view and manually edit the Master File synonym. **Note:** To update the synonym, it is strongly recommended that you use the graphical interface provided by the *Open* option, rather than manually editing the Master File.
Edit Access File as Text	Enables you to view and manually edit the Access File synonym. **Note:** This option is available only when an Access File is created as part of the synonym.
Sample Data	Retrieves up to 20 rows from the associated data source.
Data Profiling	Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.
Refresh Synonym (if applicable)	Regenerates the synonym. Use this option if the underlying object has been altered.

Option	Description
Data Management	Followed by these options, if applicable: **Recreate DBMS Table.** Recreates the data source table. You are asked to confirm this selection before the table is regenerated. (Note that the table will be dropped and recreated. During the process, data may be lost.) **Delete All Data.** Deletes all existing data. You are asked to confirm this selection before the data is deleted. **Drop Table.** Drops the table so that it is removed from the DBMS. **Insert Sample Data.** Inserts specified number of sample records, populating all fields with counter values. **Show/Modify Data.** Opens a window that shows the data in the data source with buttons you can click to insert values, filter values, reload the data source, and customize the view. **Reorganize.** Recreates the data source table preserving original data. **Note:** This option is not available in the Web Console.
Impact Analysis	Generates a report showing where this synonym is stored and used, with links to the synonym instances. Impact Analysis reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration* manual for details about Impact Analysis reports.
Dependencies Analysis	Generates a report showing information about the synonym and other synonyms and objects that are referenced within it.
Copy	Copies the synonym to the clipboard.
Delete	Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.
Cut	Deletes the synonym and places it on the clipboard.
Privileges	Shows the security subjects on the server and the privileges they have to this synonym.

Option	Description
Properties	Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

Data Type Support Report

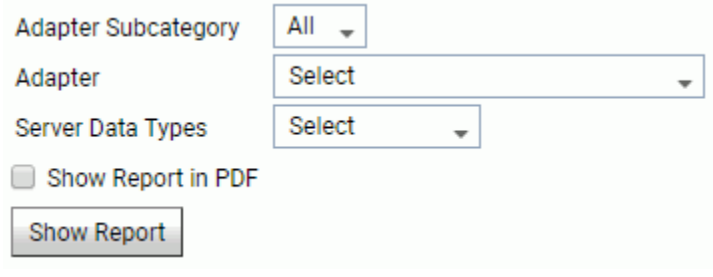
SQL Data Type mapping options are available in a report available from the Web Console.

Procedure: How to Access the Data Type Report

To access the Data Type Report:

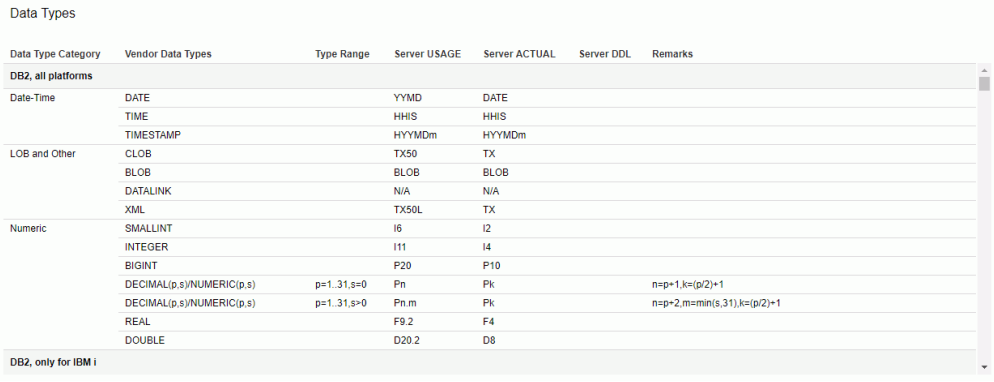
1. Select *Adapters* from the main menu.
2. From the Troubleshooting section of the Ribbon, click the *Data Types* button.

   The Filter Data Types Report page opens, as shown in the following image.



3. Select an *Adapter Subcategory* from the corresponding list box.
4. Select an *Adapter* from the corresponding list box.
5. Select a *Server Data Type* from the corresponding list box.
6. Click *Show Report*.

The Filter Data Types Report is displayed, as shown in the following image.



Data Types

Data Type Category	Vendor Data Types	Type Range	Server USAGE	Server ACTUAL	Server DDL	Remarks
DB2, all platforms						
Date-Time	DATE		YYMD	DATE		
	TIME		HHIS	HHIS		
	TIMESTAMP		HYYMDm	HYYMDm		
LOB and Other	CLOB		TX50	TX		
	BLOB		BLOB	BLOB		
	DATALINK		N/A	N/A		
	XML		TX50L	TX		
Numeric	SMALLINT		I6	I2		
	INTEGER		I11	I4		
	BIGINT		P20	P10		
	DECIMAL(p,s)/NUMERIC(p,s)	p=1..31,s=0	Pn	Pk		n=p+1,k=(p/2)+1
	DECIMAL(p,s)/NUMERIC(p,s)	p=1..31,s>0	Pn.m	Pk		n=p+2,m=min(s,31),k=(p/2)+1
	REAL		F9.2	F4		
	DOUBLE		D20.2	D8		
DB2, only for IBM i						

Note: You can also display the report as a PDF by selecting the *Show Report in PDF* check box.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

Syntax: How to Override the Default Precision and Scale

```
ENGINE ADAPTER_ID SET CONVERSION RESET
ENGINE ADAPTER_ID SET CONVERSION format RESET
ENGINE ADAPTER_ID SET CONVERSION format [PRECISION precision [scale]]
ENGINE ADAPTER_ID SET CONVERSION format [PRECISION MAX]
```

where:

ADAPTER_ID

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

The adapter values are:

Adapter	Adapter ID	Adapter	Adapter ID
Cache	dbsqlism	Db2	dbdb2
Excel	dbsqlexc	HP Vertica	dbsqlvrt
Hyperstage	dbsqlhyp	i Access	dbsqliia
CA-IDMS/DB	dbidmsr	Informix	dbsqlinf
Ingres	dbsqling	Interplex	dbsqlipx
JBoss Application Server	dbsqlmmx	JDBC	dbsqljdb
MariaDB	dbmariadb	Microsoft Access	dbsqlmac
Microsoft SQL Server	dbsqlmss	Microsoft SQL Server ODBC	dbmsodbc
MySQL	dbsqlmys	Netezza	dbsqlnez
Nucleus	dbsqlnuc	ODBC	dbsqlodb
Oracle	dbsqlora	Oracle TimesTen	dbsqlott
PostgreSQL	dbsqlpst	Progress	dbsqlpro
PSQL	dbsqlpsq	SAP Hana	dbsqlhan
Remote Servers	dbeda	Sybase	dbsqlsyb
SQLBase	dbsqlbas	Transoft	dbsqltrn
Teradata	dbsqldbc	UniVerse	dbsqluv
UniData	dbsqlund		
XML	dbxml		

RESET

Returns any previously specified precision and scale values to the adapter defaults. If you specify RESET immediately following the SET CONVERSION command, all data types return to the defaults. If you specify RESET following a particular data type, only columns of that data type are reset.

format

Is any valid format supported by the data source. Possible values are:

INTEGER which indicates that the command applies only to INTEGER columns.

DECIMAL which indicates that the command applies only to DECIMAL columns.

REAL which indicates that the command applies only to single-precision floating-point columns. Only applies to Db2, CA-IDMS/SQL, Microsoft SQL Server, and Sybase.

FLOAT which indicates that the command applies only to double-precision floating-point columns.

precision

Is the precision. Must be greater than 1 and less than or equal to the maximum allowable value for the data type (see the description of MAX).

scale

Is the scale. This is valid with DECIMAL, FLOAT and REAL data types. If you do not specify a value for scale, the current scale setting remains in effect. The default scale value is 2.

If the scale is not required, you must set the scale to 0 (zero).

MAX

Sets the precision to the maximum allowable value for the indicated data type:

Data Type	MAX Precision
INTEGER	11
DECIMAL	18
REAL	9
FLOAT	20

Note: When issuing the CREATE SYNONYM command while the CONVERSION command is active in the profile, the Master File reflects the scale and length that is set by the CONVERSION command.

However, when issuing a SELECT statement, the answer set description does not use the information in the Master File. The length and scale used for the answer set description depends on whether a CONVERSION command is in effect.

If a CONVERSION command is in effect, the answer set description uses the length and scale that is set by the CONVERSION command.

If a CONVERSION command is not in effect, the answer set description uses the actual length and scale of the data.

Example: **Setting the Precision and Scale Attributes**

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to 7:

```
ENGINE ADAPTER_ID SET CONVERSION INTEGER PRECISION 7
```

The following example shows how to set the precision attribute for all DOUBLE PRECISION fields to 14 and the scale attribute to 3:

```
ENGINE ADAPTER_ID SET CONVERSION FLOAT PRECISION 14 3
```

The following example shows how to set the precision attribute for all INTEGER and SMALLINT fields to the default:

```
ENGINE ADAPTER_ID SET CONVERSION INTEGER RESET
```

The following example shows how to set the precision and scale attributes for all fields to the defaults:

```
ENGINE ADAPTER_ID SET CONVERSION RESET
```

Metadata Services With SQLENGINE SET

When the server is dedicated to accessing one Relational Database Management System (RDBMS) using the SET SQLENGINE command in the global profile, metadata calls to the server are processed against the native catalogs of the RDBMS.

How Applications Access Metadata

The metadata procedures used by applications to query the native catalog directly are:

- For an ODBC-enabled application, ODBC SQL calls.

- For an API-enabled application, EDARPC for ODBC*xxxx* calls.

The following table shows the relationship between the ODBC call and the API call:

ODBC Call	API Call
SQLTables	ODBCTABL
SQLColumns	ODBCCOLS
SQLPrimaryKeys	ODBCPKEY
SQLStatistics	ODBCSTAT
SQLProcedures	ODBCPROC
SQLProcedureColumns	ODBCPRCC
SQLSpecialColumns	ODBCSCOL
SQLColumnPrivileges	ODBCCPRV
SQLForeignKeys	ODBCFKEY
SQLTablePrivileges	ODBCTPRV

You can use the following two commands to control or override table and column metadata calls:

```
SQL sqlengine SET ODBCCOLSSORT
```

```
SQL sqlengine SET ODBCTABL
```

You can include these commands in any of the supported server profiles.

Obtaining Column Information (Db2 only)

When you issue either the SQLColumns or ODBCCOLS Metadata call from a client application, by default, the server requests the columns from Db2 in *colno* order.

Syntax: How to Request the Sort Order of Column Data

```
SET ODBCCOLSSORT {ON|OFF}
```

where:

ON

The column data is requested from the server with order by colno. This value is the default.

OFF

The column data is returned in unsorted order.

Obtaining User-Defined Metadata

When a client application issues either an ODBC or API metadata call, the server runs internal procedures that issue default SQL against the native RDBMS catalogs. You can issue your own SQL to run in place of the default SQL. You can specify this type of override for any of the internal server routines that deal with metadata.

Syntax: How to Request User-Defined Metadata

```
SQL sqlengine SET ODBCxxxx procname
```

where:

ODBC*xxxx*

Is the internal server routine name. Possible values are: ODBCTABL, ODBCCOLS, ODBCPKEY, ODBCSTAT, ODBCPROC, ODBCPRCC, ODBCSCOL, ODBCCPRV, ODBCFKEY, and ODBCTPRV.

procname

Is the procedure to run when the server receives the metadata call. This procedure must be available through the FOCEXEC ddname allocation in the server JCL.

Note: If this override procedure is used on a server running under MVS, it will add approximately 600K of storage above the line for each user.

When coding an override procedure, care must be taken to maintain the select list (answer set layout). The select list must conform to the ODBC specification for the return from the SQLTables call. See the *ODBC 2.0 Programmer's Reference and SDK Guide* for the SQLTables specification layout. Also, when using this override procedure, the parameters that are sent with the Metadata call need to be parsed correctly.

The override procedure should take the following format:

1. Dialogue Manager code to parse metadata call parameters.
2. `SQL sqlengine SELECT code;`

3.
```
TABLE
ON TABLE PCHOLD FORMAT ALPHA
END
```

Items 1 and 2 above are user coded; item 3 must always be present at the end of the procedure as coded above.

Example: Returning a List of Tables

The following sample code found in *qualif*.EDARPC.DATA(DB2ODBC1) returns a list of tables that the connected user is authorized to INSERT, UPDATE, DELETE, and SELECT. It is a sample of how to code a Db2 override procedure for ODBCTABL. It is one of several ways to code SQL to return an answer set for the ODBCTABL call. You can code any relevant query as long as the SELECT list is maintained.

In a server profile, issue SQL DB2 SET ODBCTABL DB2ODBC1, and then execute the following RPC request on the server:

```
ODBCTABL  ,<NULL>,,,,0,0,*
```

The following example matches the above ODBCTABL call:

```
-*
-* Dialogue Manager code to parse the ODBCTABL parameter list
-*
-DEFAULTS 1=' ',2='%',3='%'
-IF &2 NE '<NULL>' THEN GOTO LAB1;
-SET &2 = '%';
-LAB1
-IF &3 NE ' ' THEN GOTO LAB2;
-SET &3 = '%';
-LAB2
-*
-* SQL SELECT code
-*
SQL DB2
SELECT ' ',T2.CREATOR,T2.NAME,'TABLE',' '
FROM SYSIBM.SYSTABAUTH T1,SYSIBM.SYSTABLES T2
WHERE T1.GRANTEE  = USER
AND   T1.TTNAME   LIKE '&2'
AND   T1.TCREATOR LIKE '&3'
AND   T2.TYPE     = 'T'
AND  (T1.DELETEAUTH IN  ('G','Y')
OR    T1.INSERTAUTH IN  ('G','Y')
OR    T1.SELECTAUTH IN  ('G','Y')
OR    T1.UPDATEAUTH IN  ('G','Y'))
AND   T1.TTNAME   = T2.NAME
AND   T1.TCREATOR = T2.CREATOR
UNION
```

```
SELECT ' ',T2.CREATOR,T2.NAME,'VIEW',' '
FROM SYSIBM.SYSTABAUTH T1,SYSIBM.SYSTABLES T2
WHERE T1.GRANTEE  = USER
AND   T1.TTNAME   LIKE '&1'
AND   T1.TCREATOR LIKE '&2'
AND   T2.TYPE     = 'V'
AND  (T1.DELETEAUTH IN  ('G','Y')
OR    T1.INSERTAUTH IN  ('G','Y')
OR    T1.SELECTAUTH IN  ('G','Y')
OR    T1.UPDATEAUTH IN  ('G','Y'))
AND   T1.TTNAME   = T2.NAME
AND   T1.TCREATOR = T2.CREATOR
ORDER BY CREATOR,NAME;
-*
-* The following code must always be present
-*
TABLE
ON TABLE PCHOLD FORMAT ALPHA
END
```

Maintaining Upward Compatibility

In Version 4.3.x or earlier, an Extended Catalog (SYSOWNER table) was created at installation time. This provided additional control to the list of tables returned with the SQLTables or ODBCTABL call. In Version 5.1.0 and higher, this table is no longer created. If you need to use this table from a previous version of the server to continue to have control over the list of tables, issue the following in any supported server profile:

```
SQL sqlengine SET OWNERID ownerid
```

where:

sqlengine

Indicates the data source. You can omit this value if you previously issued the SET SQLENGINE command.

ownerid

Identifies the creator or owner of the Extended Catalog table SYSOWNER. If this command is used, the SQL generated to provide a list of tables will be limited by the owner names in the SYSOWNER table.

This command is only supported for customers who have configured a Relational Gateway in previous releases of the server and want to continue with the same configuration.

Additional Master File Attributes

These topics describe how to modify your server and communications configuration files.

The following attributes enable you to provide descriptive information about tables and columns.

`REMARKS`

Is an optional attribute for documenting tables.

`DESCRIPTION`

Is an optional attribute for documenting columns.

`TITLE`

Is an optional attribute for supplying an alternate column title on a report to replace the FIELDNAME value, which is normally used.

For the server, client tools using the API or ODBC will not use the TITLE attribute. The TITLE attribute is available only when directly querying the server catalog.

Documenting a Table

The REMARKS attribute enables you to document a table.

Syntax: How to Document a Table

The syntax is

```
REMARKS=text ,$
```

where:

text

Is one line of text. It can consist of a maximum of 78 characters. If the text contains a comma, you must enclose the text in single quotation marks.

The REMARKS attribute cannot span more than one line in the Master File. If necessary, move the entire attribute to a line by itself.

Example: Documenting an Oracle Table

The following example shows how to document the Oracle table SAMPLE.

```
FILE=SAMPLE,SUFFIX=SQLORA,REMARKS=This is a sample Oracle table.,$
```

Documenting a Column

The DESCRIPTION attribute enables you to provide a comment for a column in a table.

You can also add documentation to a column declaration—or a segment or table declaration—by typing a comment following the terminating dollar sign. You can even create an entire comment line by inserting a new line following a declaration and placing a dollar sign at the beginning of the line. For the server, a comment added in this manner will not be available to any client application.

If you are using DEFINE fields in a Master File, you must place the DESCRIPTION attribute on a line by itself. The semicolon after the DEFINE must appear on the same line as DESCRIPTION=.

Syntax: How to Document a Column

The syntax is

```
DESC[RIPTION]=text ,$
```

where:

text

Is one line of text. It can consist of a maximum of 44 characters.

If the text contains a comma, you must enclose the text in single quotation marks.

The DESCRIPTION attribute cannot span more than one line in the Master File. If necessary, move the entire attribute to a line by itself.

Note: Whenever possible, place the description on the same line with the attributes FIELDNAME and ALIAS, to conserve space.

Example: Documenting a Column

The following example shows how to provide a description for the column UNITS. The single quotation marks are required because the description contains a comma.

```
FIELD=UNITS,ALIAS=QTY,FORMAT=I6,DESC='This is quantity sold, not
returned',$
```

Example: Documenting a DEFINE Field

The following example shows how to provide a description for the DEFINE field ITEMS_SOLD.

```
DEFINE ITEMS_SOLD/D8=ORDERED-INVENTORY
;DESC=DAMAGED ITEMS NOT INCLUDED,$
```

Supplying an Alternate Column Title

When you generate a report, each column title in the report defaults to the name of the column as it appears in the table. However, you can change the default column title by specifying the TITLE attribute.

For the server, client tools using the API or ODBC will not use the TITLE attribute. The TITLE attribute is available only when directly querying the server catalog, or when using WebFOCUS (Windows version).

You can override both the FIELDNAME and TITLE attributes with AS phrases in your report request. To override an existing TITLE attribute, use the SET TITLE command. To control whether the TITLE attribute is propagated in the Master File of a HOLD file, use the SET HOLDATTR command.

The TITLE attribute has no effect in a report if the column is used with a prefix operator such as AVE. You can supply an alternate column title for columns with prefix operators by using the AS phrase.

If you are using DEFINE fields in a Master File, you must place the TITLE attribute on a line by itself. The semicolon after the DEFINE must appear on the same line as TITLE=.

Syntax: How to Change the Default Column Title

The syntax is:

```
TITLE='text' ,$
TITLE='text,text,...' ,$
TITLE='text   /' ,$
```

where:

text

Is any string that consists of a maximum of 64 characters.

You can split the text across as many as five separate lines. Use single quotation marks to delimit the text, and commas to divide the text into separate lines on the report output.

You can include blanks at the end of an alternate column title by entering a slash (/) in the last position that will be blank, followed by a closing single quotation mark.

The TITLE attribute cannot span more than one line in the Master File. If necessary, move the entire attribute to a line by itself.

Example: Changing the Default Column Title

The following example shows how to replace the default column title, LNAME, with a title of Client Name.

```
FIELD=LNAME,ALIAS=LN,FORMAT=A15,TITLE='Client Name',$

Client Name
-----------
```

Example: Changing the Default Column Title to a Two-line Column Title

The following example shows how to replace the default column title, LNAME, with a two- line column title of Client Name.

```
FIELD=LNAME,ALIAS=LN,FORMAT=A15,TITLE='Client,Name',$

Client
Name
------
```

Example: Controlling the Underline for a Column Title

The following example shows how to control the length of the underline for an alternate column title.

```
FIELD=LNAME,ALIAS=LN,FORMAT=A15,TITLE='Client,Name     /',$

Client
Name
---------------
```

Example: Specifying a Column Title for a DEFINE Field

The following example shows how to replace the default column title for the DEFINE field, ITEMS_SOLD, with a two-line column title of Items Sold.

```
DEFINE ITEMS_SOLD/D8=ORDERED-INVENTORY;TITLE='Items,Sold',$

Items
Sold
-----
```

Specifying an Online Help Message

The HELPMESSAGE attribute enables you to specify an online help message for a field on a data entry screen. It is available only for FOCUS data maintenance applications.

When a Help Message Appears

Messages specified with the HELPMESSAGE attribute appear in the TYPE area of the CRTFORM when you:

- Enter a value for a database field that is invalid according to the criteria defined by the ACCEPT attribute.
- Enter a value for a database field that fails a VALIDATE test.
- Enter a value for a database field that causes a format error.
- Place the cursor in a data entry field and press a help key.

Regardless of the condition that triggers the display of the help message, the same message will appear.

Syntax: How to Specify a Help Message

The syntax is

```
HELP[MESSAGE]=text ,$
```

where:

text

Is one line of text. It can consist of a maximum of 78 characters.

You can use all characters and digits. If the text contains a comma, you must enclose the text in single quotation marks. Leading blanks are ignored.

The HELPMESSAGE attribute cannot span more than one line in the Master File. If necessary, move the entire attribute to a line by itself.

Example: Displaying a Help Message to List Valid Values for a Column

The following example shows how to display a help message when the DEPARTMENT value is other than MIS, PRODUCTION, or SALES. DEPARTMENT has an ACCEPT attribute which tests values entered for it.

```
FIELDNAME=DEPARTMENT,ALIAS=DPT,FORMAT=A10,
   ACCEPT=MIS PRODUCTION SALES,
   HELPMESSAGE='DEPARTMENT MUST BE MIS, PRODUCTION, OR SALES',$
```

If you enter a value other than MIS, PRODUCTION, or SALES for DEPARTMENT on a CRTFORM, both the default message and help message display on the screen:

```
DATA VALUE IS NOT AMONG ACCEPTABLE VALUES FOR DEPARTMENT
DEPARTMENT MUST BE MIS, PRODUCTION, OR SALES
```

Example: Displaying a Help Message When a Format Error Occurs

The following example shows how to display a help message when a format error occurs in HIRE_DATE. Note that the format for HIRE_DATE is integer.

```
FIELDNAME=HIRE_DATE,ALIAS=HDT,FORMAT=I6YMD,
HELPMESSAGE=THE FORMAT FOR HIRE_DATE IS I6YMD,$
```

If you enter alphanumeric characters for HIRE_DATE on a CRTFORM, both the default message and help message display on the screen:

```
FORMAT ERROR IN VALUE ENTERED FOR FIELD HIRE_DATE
THE FORMAT FOR HIRE_DATE IS I6YMD
```

Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

Optimizing Requests

The adapter can optimize DML requests by creating SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Setting*s from the menu. The Change Settings pane opens.

Syntax: How to Optimize Requests

```
SQL ADAPTER_ID SET {OPTIMIZATION|SQLJOIN} setting
```

where:

ADAPTER_ID

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

The adapter values are:

Adapter	Adapter ID	Adapter	Adapter ID
1010data	sql1010	Cache	dbsqlism
Db2	dbdb2	Excel	dbsqlexc
HP Vertica	dbsqlvrt	Hyperstage	dbsqlhyp
i Access	dbsqliia	CA-IDMS/SQL	dbsqlidm
Informix	dbsqlinf	Ingres	dbsqling
Interplex	dbsqlipx	JBoss Application Server	dbsqlmmx
JDBC	dbsqljdb	MariaDB	dbmariadb
Microsoft Access	dbsqlmac	Microsoft SQL Server	dbsqlmss
Microsoft SQL Server ODBC	dbmsodbc	MySQL	dbsqlmys
Netezza	dbsqlnez	Nucleus	dbsqlnuc
ODBC	dbsqlodb	Oracle	dbsqlora
Oracle TimesTen	dbsqlott	PostgreSQL	dbsqlpst
Progress	dbsqlpro	PSQL	dbsqlpsq
SAP Hana	dbsqlhan	SQLBase	dbsqlbas
Sybase	dbsqlsyb	Teradata	dbsqldbc
Transoft	dbsqltrn	UniData	dbsqlund
UniVerse	dbsqluv		

`SQLJOIN`

Is a synonym for OPTIMIZATION.

setting

Is the optimization setting. Valid values are as follows:

ON instructs the adapter to create SQL statements that take advantage of RDBMS join, sort, and aggregation capabilities. Note that the multiplicative effect may disable optimization in some cases. However, misjoined unique segments and multiplied lines in PRINT-based and LIST-based report requests do not disable optimization. This is the default.

OFF instructs the adapter to create SQL statements for simple data retrieval from each table. The server handles all aggregation, sorting, and joining in your address space or virtual machine to produce the report.

Both OPTIMIZATION settings produce the same report.

Example: SQL Requests Passed to the RDBMS With Optimization OFF

This example demonstrates SQL statements generated without optimization. The report request joins tables EMPINFO and FUNDTRAN with trace components SQLAGGR and STMTRACE allocated.

When optimization is disabled, the data adapter generates two SELECT statements. The first SELECT retrieves any rows from the EMPINFO table that have the value MIS in the DEPARTMENT column. For each EMPINFO row, the second SELECT retrieves rows from the cross-referenced FUNDTRAN table, resolving the parameter marker (?, :000*n*, or :H, depending on the RDBMS) with the value of the host field (EMP_ID). Both SELECT statements retrieve answer sets, but the server performs the join, sort, and aggregation operations:

```
SQL ADAPTER_ID SET OPTIMIZATION OFF
 JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
 TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
 END
```

In a trace operation, you will see the following output:

```
(FOC2510) FOCUS-MANAGED JOIN SELECTED FOR FOLLOWING REASON(S):
(FOC2511) DISABLED BY USER
(FOC2590) AGGREGATION NOT DONE FOR THE FOLLOWING REASON:
(FOC2592) RDBMS-MANAGED JOIN HAS BEEN DISABLED
  SELECT T1.EID,T1.LN,T1.DPT,T1.CSAL,T1.OJT
    FROM 'USER1'.'EMPINFO' T1 WHERE (T1.DPT = 'MIS') FOR FETCH ONLY;
  SELECT T2.EID FROM 'USER1'.'FUNDTRAN' T2 WHERE (T2.EID = ?)
    FOR FETCH ONLY;
```

Example: SQL Requests Passed to the RDBMS With Optimization ON

With optimization enabled, the data adapter generates one SELECT statement that incorporates the join, sort, and aggregation operations. The RDBMS manages and processes the request. The server only formats the report.

```
SQL ADAPTER_ID SET OPTIMIZATION ON
 JOIN EMP_ID IN EMPINFO TO ALL WHO IN FUNDTRAN AS J1
 TABLE FILE EMPINFO
  SUM AVE.CURRENT_SALARY ED_HRS BY WHO BY LAST_NAME
  IF DEPARTMENT EQ 'MIS'
 END
```

In a trace operation, you will see the following output:

```
AGGREGATION DONE ...
    SELECT T2.EID,T1.LN, AVG(T1.CSAL), SUM(T1.OJT)
      FROM 'USER1'.'EMPINFO' T1,'USER1'.'FUNDTRAN' T2
      WHERE (T2.EID = T1.EID) AND (T1.DPT = 'MIS')
      GROUP BY T2.EID,T1.LN
      ORDER BY T2.EID,T1.LN;
```

Reference: SQL Generation in Optimization Examples

There are minor differences in the specific SQL syntax generated for each RDBMS. However, the adapter messages are the same and the generated SQL statements are similar enough that most examples will illustrate the SQL syntax generated by any relational adapter.

Optimizing Requests to Pass Virtual Fields Defined as Constants

A virtual field defined as a constant is passed directly to an SQL database engine (RDBMS) for optimized processing that takes advantage of RDBMS join, sort, and aggregation capabilities, thus reducing the volume of RDBMS-to-server communication and improving response time. (In prior releases, constants were not passed to the database engine, causing optimization to be turned off.)

Constants in the following formats are passed to the RDBMS: NUMERIC, CHAR, VARCHAR, CHAR/INTEGER combination, and DATE. (Note that a few formats are *not* passed to the RDBMS; these are CHAR and VARCHAR combination, TIME, and DATETIME.)

When valid constants are passed to an RDBMS engine, a report is calculated based on the defined value(s) and only the calculated subset of records is returned. The extent of data manipulation at the adapter level is limited, thereby improving performance.

Example: Passing Numeric Constants

```
DEFINE FILE SMIX87
INTEGERCONST/I4 = 5
REALCONST/D20.2 = -97995.38
NUMERICCONST/P13.4 = -92999.3647

TABLE FILE SMIX87
 SUM INTEGERCONST REALCONST NUMERICCONST MAX.QUOT.FA01INTEGER
 BY QUOT.FA02INTEGER
 END
```

The following SQL is generated:

```
SELECT T2."FA02INTEGER", SUM(5), SUM(-97995.38),
   SUM(-92999.3647), MAX(T2."FA01INTEGER") FROM TMIX83A T2 GROUP
   BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

Example: Passing a CHAR Constant

```
DEFINE FILE SMIX87
 CHARCONST/A10 = '2N'

TABLE FILE SMIX87
 SUM CHARCONST MIN.FA02CHAR_15
 BY QUOT.FA02INTEGER
 END
```

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), MIN(T3."FA02CHAR_15") FROM
   TMIX83A T2,TMIX86A T3 WHERE (T3."FA01INTEGER" =
   T2."FA01INTEGER") GROUP BY T2."FA02INTEGER" ORDER BY
   T2."FA02INTEGER";
```

Example: Passing CHAR and INTEGER Constants

```
DEFINE FILE SMIX87
 CHARCONST/A10 = '2N'
 INTEGERCONST/I4 = 5

TABLE FILE SMIX87
SUM CHARCONST INTEGERCONST
BY QUOT.FA02INTEGER
END
```

The following SQL is generated:

```
SELECT T2."FA02INTEGER", MAX('2N'), SUM(5) FROM TMIX83A T2
GROUP BY T2."FA02INTEGER" ORDER BY T2."FA02INTEGER";
```

Chapter 2

Using the Adapter for 1010data

The Adapter for 1010data allows applications to access specific 1010data databases. The adapter converts application requests into 1010data calls and returns optimized answer sets to the requesting application.

The adapter utilizes the ODBC API and is only available on Windows. The adapter is READ-ONLY. It does not support inserting data into 1010data tables in any way.

In this chapter:

Configuring the Adapter for 1010data

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Preparing the 1010data Environment

To use the Adapter for 1010data, you must first install the 1010data ODBC driver and all related libraries. To use this driver, you must configure a working data source via the ODBC Data Source Administrator. The Adapter will use this data source to access the 1010data database.

Configuring the Adapter

In order to connect to the 1010data database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).

- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one 1010data database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the 1010data Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for 1010data

The 1010data adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

The data source name (DSN). There is no default data source name. You must enter a value.

This is the data source set in the ODBC Data Source Administrator.

Security

There are two methods by which a user can be authenticated when connecting to a data source:

- **Explicit.** The user ID and password are explicitly specified for each connection pass to the ODBC data source, at connection time, for authentication.
- **Trusted.** The adapter connects to the ODBC data source as a Windows login using the credentials of the operating system user impersonated by the server data access agent.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

File DSN parameters (optional)

Is the path to the ODBC File DSN that is defined on your Windows machine or network.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

For User/System DSN:

```
ENGINE SQL1010 SET CONNECTION_ATTRIBUTES connection
   DSNname/user_name,password,
```

For File DSN:

```
ENGINE SQL1010 SET CONNECTION_ATTRIBUTES connection
    FileDSN_name/,:'filedsn=FileDSN_path;',
```

where:

`SQL1010`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and DSN_*name*.

DSN_*name*

Is the 1010data Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

user_name

Is the primary authorization ID by which you are known to an 1010data data source.

password

Is the password associated with the primary authorization ID.

FileDSN_*name*

Is the name of 1010data File Data Source Name (DSN) you wish to access.

FileDSN_*path*

Is the path to the 1010data File DSN, which may reside on the hard drive or on the network.

Example: Declaring Connection Attributes

For User/System DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the 1010data DSN named SAMPLESERVER.

```
ENGINE SQL1010 SET CONNECTION_ATTRIBUTES CON1
  SAMPLESERVER/SAMPLEUSER,SAMPLEPASSWORD,
```

For File DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 via the ODBC File DSN named SAMPLESERVER.dsn.

```
ENGINE SQL1010 SET CONNECTION_ATTRIBUTES CON2
SAMPLESERVER.dsn /,:'filedsn=C:\ SAMPLESERVER.dsn;'
```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQL1010 SET DEFAULT_CONNECTION connection
```

where:

`SQL1010`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQL1010 SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQL1010 SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

`SQL1010`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMAND`

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing 1010data Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the 1010data data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQL1010 to identify the Adapter for 1010data.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQL1010 [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQL1010

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each 1010data table or sheet that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.

- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for 1010data

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Note: Due to internal settings of the 1010data, filtering by Owner/Schema might not be applicable to some database objects.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.

- ❑ To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for 1010data synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File

```
FILENAME=ONHAND, SUFFIX=SQL1010, $
  SEGMENT=ONHAND, SEGTYPE=S0, $
    FIELDNAME=PROD_NUM, ALIAS=Prod_Num, USAGE=A255V, ACTUAL=A255V,
      MISSING=ON, $
    FIELDNAME=PRODNAME, ALIAS=Prodname, USAGE=A255V, ACTUAL=A255V,
      MISSING=ON, $
    FIELDNAME=QTY_IN_STOCK, ALIAS=Qty_in_Stock, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
    FIELDNAME=PRICE, ALIAS=Price, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
    FIELDNAME=COST, ALIAS=Cost, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
```

Access File

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DB1,KEYS=1,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File for 1010data.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the 1010data table. The value assigned to this attribute can include the name of the workbook as follows: TABLENAME=[*filename*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* Absence of the CONNECTION attribute indicates access to the default database server.

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support

Data types are specific to the underlying data source.

Customizing the 1010data Environment

The Adapter for 1010data provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to 1010data.

Syntax: **How to Issue the TIMEOUT Command**

```
ENGINE SQL1010 SET TIMEOUT {nn|0}
```

where:

SQL1010

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

0

Represents an infinite period to wait for a response.

1010data Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 3

Using the Adapter for Adabas

The Adapter for Adabas allows applications to access Adabas data sources. The adapter converts application requests into native Adabas statements and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the Adabas Environment

Adabas environment variables must be set before you configure the server. Refer to the Software AG documentation for more information about required environment variables.

Procedure: How to Prepare the Adabas Environment on Windows

On Windows, the Adabas environment is set up during the installation of Adabas.

Procedure: How to Prepare the Adabas Environment on UNIX

1. Specify the Adabas database directories to access using the UNIX environment variable $ACLDIR . For example:

```
ACLDIR =/rdbms/sag/acl
export ACLDIR
```

2. Specify the Adabas driver using the UNIX environment variable $ADALNK. For example:

```
ADALNK=/rdbms/sag/ada/v6xxx/adalnkx.so
export ADALNK
```

3. Specify the version of the Adabas product using the UNIX environment variable $ADAVERS. For example:

```
ADAVERS=v6xxx
export ADAVERS
```

Procedure: How to Prepare the Adabas Environment on OpenVMS

When a site creates an Adabas ID, the software automatically generates a DCL setup script so users can properly invoke the environment.

The specification for the location of the Adabas setup file is

```
$@SAG$ROOT:[adabas_root]LOGIN.COM
```

where:

`SAG$ROOT`

Is the disk on which Adabas is installed.

`adabas_root`

Is the root directory of the Adabas installation.

Example: Specifying the Adapter for Adabas on OpenVMS

```
$@SAG$ROOT:[Adabas]LOGIN.COM
```

The logicals ADABAS$MAIN, ADALNK, and ADABAS$VERSION will be used to communicate with Adabas Nucleus.

Procedure: How to Prepare the Adabas Environment on z/OS

Before starting the server, you can specify the name of the CEE LKED PDS by exporting the environment variable CEELKED. The default value is the standard IBM name, CEE.SCEELKED. If you wish to override the default, define the variable as follows

```
CEELKED=cee_lked_pds
```

on the EDAENV member of the *high_level_qualifier.server_type*.DATA.

The CELLKED variable value (either the default or a value you specify) is displayed along with other environment parameters, such as STEPLIB and LIBPATH, in the lower section of the Adabas Configuration pane on the Web Console.

Configuring the Adapter for Adabas

Configuring the adapter consists of specifying connection information for each of the connections you want to establish.

No user ID and password are needed to establish a connection to Adabas. This means that Trusted Mode is the standard for Adabas. To secure a connection, use the SET PASSWORD feature.

Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note:

- On z/OS platforms, the adapter needs to be configured before connections can be tested.
- More than one connection can be configured. To add connections, right-click the *Adabas* folder, choose *Add Connection* and repeat Steps 5 and 6.

Reference: Connection Attributes for Adabas

The Adabas adapter is under the *DBMS* group folder.

This following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection Name

Is the logical name used to identify this particular set of connection attributes. There is no default Connection Name. You must provide a value.

The Connection Name is a new parameter added in Version 7 Release 7.4. It is designed to support access to different databases with different SVCs and releases through the same adapter. It corresponds to the new CONNECTION parameter in an Access File.

The adapter continues to support connection strings and Access Files without a Connection Name parameter, as they were declared prior to Version 7 Release 7.4.

Note that the connection name <*local*> will be displayed on the Web Console for the legacy connection strings.

Users may assign a more meaningful name instead. For example, the legacy connection

```
ENGINE ADBSINX SET CONNECTION_ATTRIBUTES
/,;3:',ADAEMPL=1,ADASVC=214,ADADEVICE=3,390,ADAASSO=SAGLIB.ADA814.
IBIMVS.DB03.ASSOR1'
```

can be converted into new connection supported since Version 7 Release 7.4

```
ENGINE ADBSINX SET CONNECTION_ATTRIBUTES
ADA814/,;3:',ADAEMPL=1,ADASVC=214,ADADEVICE=3,390,ADAASSO=SAGLIB.ADA814.IBIMVS.DB03
.ASSOR1'
```

Default DB number

Number of the database to access. For example: 001(Required for all platforms.)

SAG Employee/Demo file number

Number of the Adabas Employee or another Demo File. For example: 011 (Required for all platforms.)

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

SVC number

SVC number of the Adabas router. For example: 240 (Required only for z/OS.)

Device type

Type of device where the Adabas Associator is located. For example: 3390 (Required only for z/OS.)

ADABAS Load Library name

Name of the Adabas load library that contains the zapped member ADALNKR (see notes below). This name needs to be added after the IBI load library; the order is important. For example:

```
//TASKLIB ...
   // DD DISP=SHR,DSN=IBI.HOME.LOAD
   // DD DISP=SHR,DSN=SAGLIB.ADA814.LOAD
   ...
```

(Required only for z/OS.)

Associator data set name

Name of the Adabas Associator data set. For example: SAGLIB.ADA814.EXAMPLE.DB001.ASSOR1 (Required only for z/OS.)

ADABAS LOAD library

This parameter is needed only if the Adapter will be used to access Adabas databases with different SVCs. It lets you specify your own high_level_qualifier for each database.

If only one SVC is used, this parameter is not needed.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the *Profile Name* field (The extension is added automatically).

Store the connection attributes in the server profile (edasprof).</p>

Note:

- The Adabas adapter configuration procedure was changed starting with the Version 7 Release 7 of the server. This procedure no longer uses SVC, since starting with Adabas 8, Software AG no longer provides a source for ADALNK. The ADALNKR needs to be prepared as described in the Software AG Adabas 8 documentation. See *Installing Adabas with TP Monitors* under the *Installing Adabas with Batch/TSO under Adabas 8* chapter. The Default SVC number needs to be zapped into ADALNKR prior to the Adabas adapter configuration step.
- The correct SVC number still needs to be provided on the configuration screen. It is used by adapter to create synonyms and in other routines.

Overriding Default Passwords in Specific Files

You can set passwords for Adabas files in the server profile using the SET PASSWORD command. You can set default passwords for all files and/or databases. Specific passwords can be set for specific files which will override the default. The SET command overrides the password coded in the Access File. The SET PASSWORD command remains valid throughout the user session.

Syntax: How to Use the SET PASSWORD Command

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET PASSWORD password FILENO ALL DBNO {ALL|dbno}
ENGINE ADBSINX SET PASSWORD password FILENO fileno DBNO dbno
ENGINE ADBSINX SET PASSWORD OFF
ENGINE ADBSINX SET PASSWORD DEFAULT
```

where:

`ADBSINX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

password

Is the password, which can be from one to eight characters in length.

FILENO

Specifies the file number for which the password is set.

DBNO

Specifies the database or databases for which the password is set.

ALL

Indicates all files and/or databases used with the FILENO and DBNO parameters. If you want to use ALL for both FILENO and DBNO, issue this command before any other subsequent password commands. ALL overrides any prior settings.

dbno

Is any valid numeric database value between 0 and 255 (65,535 is the maximum value on a mainframe platform). The DBNO parameter indicates the actual database number.

fileno

Provides a file number, a list of file numbers, and/or a range of file numbers used with the FILENO parameter. Numbers and ranges can be combined by separating items with commas. Valid file numbers range between 0 and 255 (5000 is the maximum value on a mainframe platform).

OFF

Clears all previous ADBSINX SET PASSWORD commands. The Adapter for Adabas does not use any passwords specified in the Access File. This command lets you access only those files that have no password security.

DEFAULT

Clears all previous ADBSINX SET PASSWORD commands and causes the Adapter for Adabas to use the password in the Access File.

To set a default password:

- Issue the SET PASSWORD command using the ALL keyword for FILENO and/or DBNO.
- Issue specific password requests by specifying particular file and/or database numbers (or ranges) in a subsequent SET PASSWORD command.

Note that subsequent requests are appended to previous requests. Changes are cumulative. The passwords can be issued from a FOCEXEC, which may be encrypted.

Example: Using the SET PASSWORD Command to Specify Files in a Database

To set the password to BRUCE for specific files in database number 123 on z/OS, issue the following command:

```
ENGINE ADBSINX SET PASSWORD BRUCE FILENO 1,3-5,23,89-93 DBNO 123
```

To clear all previous ADBSINX SET PASSWORD commands on z/OS, and tell Adabas to use the password in the Access File, issue the following command:

```
ENGINE ADBSINX SET PASSWORD DEFAULT
```

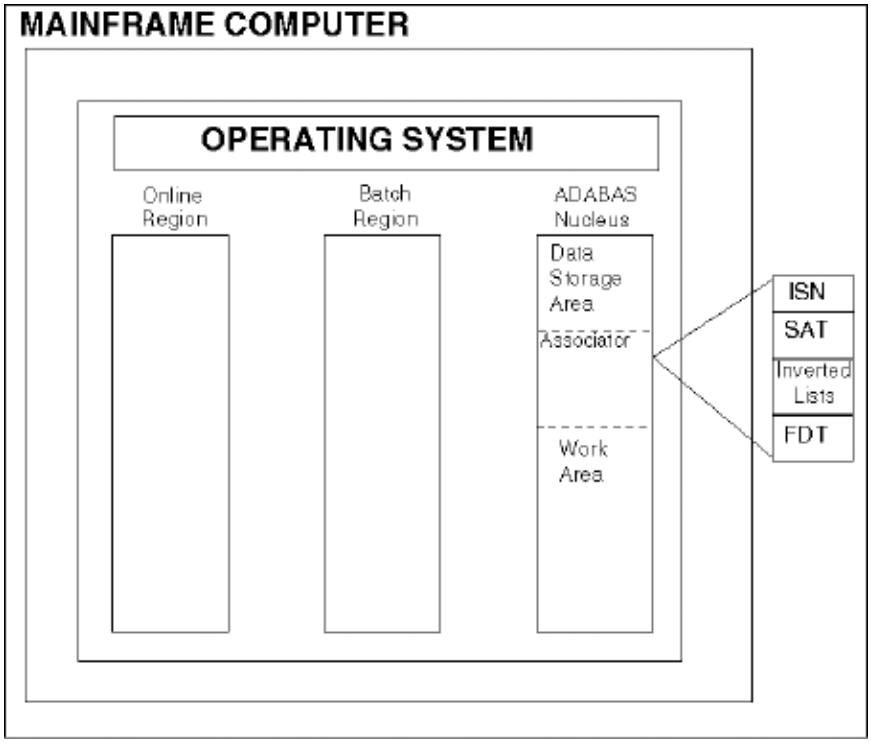
Adabas Overview

This topic provides an overview of Adabas and Adabas files, and includes a discussion of server concepts.

Adabas is a field-oriented DBMS. Data retrievals and updates are performed on a field-by-field basis.

Since Adabas data retrieval occurs at the field level rather than at the record level, your applications may be designed without consideration for the physical organization and maintenance of the record. Data is accessed in a variety of ways (in physical sequence, in logical sequence, or by Internal Sequence Numbers), thereby enabling you to tailor data access to address your specific needs.

The Adabas DBMS consists of several components. The following is an illustration of the Adabas environment.



This table describes the components of the Adabas environment.

Component	Description
Operating System	Set of programs (software) that control the operation of the computer (hardware).
Online Region	Part of the Dynamic Area of the computer. It is the section in which multiple jobs execute simultaneously. The Online Region is also known as the Foreground Region (applies only to TSO).
Batch Region	Part of the Dynamic Area of the computer. Jobs become a series of commands that are grouped together and processed in batches (applies only to batch jobs).

Component	Description
Data Storage Area	Contains the actual data. The data is stored in compressed form.
Associator	Stores relationships about the data. It contains the following components: ❏ Internal Sequence Number (ISN) list, also called the Address Converter, used to determine the physical location of data. ❏ Space Allocation Tables (SATs) to control storage space. ❏ Inverted lists for the defined descriptors. Inverted lists and descriptors are discussed in *Inverted Lists: The Adabas Key Structure* on page 139. ❏ Field Definition Tables (FDTs), which contain detailed data structure information for each field and descriptor.
Work Area	Is a "scratch pad" used by Adabas to build ISN lists and to sort and store records that your program requires.

The Multi-Programming Module (MPM), the cornerstone of the Adabas Nucleus, contains the logic that enables multiple programs, both batch and online, to access Adabas databases simultaneously.

Each database has its own data storage area, associator, and work area, in addition to its own unique database number.

Adabas Files

When accessing Adabas, the server uses logical files as the unit of data retrieval. An Adabas file is identified by a file number. The number is unique within each database.

All file and field documentation for the Adabas database can be stored in the Predict dictionary. The information about the data structure includes processing uses, file ownership, and field descriptions.

Inverted Lists: The Adabas Key Structure

An Adabas file is defined with a set of indexes called descriptors. The Adabas term for these values, which reside in the File Associator Table, is inverted lists. Inverted lists contain the values of descriptors, a count of the total number of records in which each value appears, and the Internal Sequence Numbers (ISNs), in ascending order, associated with each occurrence.

Adabas utilities create and maintain an inverted list for each descriptor identified. These lists store data in an ascending sequence by the value of the key. A single file may have up to 256 inverted lists associated with it.

The descriptors are identified to speed data location and to retrieve specific, frequently required data from Adabas files. Of the available types of inverted lists, the Adapter for Adabas supports the following.

Inverted List	Description
Descriptors	Key values associated with a single field (also called elementary field descriptors).
Subdescriptors	Key values associated with part of a single field.
Superdescriptors	Key values associated with all or part of two to twenty fields.
Phonetic descriptors	Alphabetic values associated with the first twenty bytes of the field value.
Hyperdescriptors	A value generated, based on a user-supplied algorithm.

In the following text, descriptor refers to all five types of descriptors interchangeably, unless otherwise indicated.

Two or more files may be related in these ways:

- The database administrator may couple several files based on a common descriptor key in each file.
- An application program may logically relate files if there are fields in one file that can be used to access a key in another.

Field Definition Tables

Field description information for Adabas files is maintained in the FDT, which is part of the Adabas associator. Adabas uses this information when accessing files. The FDT includes the following information:

Field Information	Description
Field Level Indicator	Denotes a hierarchical relationship between fields. In an Adabas record description the levels are 1, 2, 3, and so on.
Adabas Field Name	Two-character name used by Adabas to identify the field. This name is unique to the file. The first character must be alphabetic, and the second character can be alphabetic or numeric. Field names E0 through E9 are reserved for internal Adabas use.
Standard Length	Length of the field in bytes.
Standard Format	Format of the field. Refer to the table in *Standard Formats for Adabas Fields* on page 141 for the acceptable formats and their meanings.
Field Properties	Indicates whether the field value is null suppressed (NU), the field is of fixed or variable length (FI), or if the field (which exists on a mainframe platform) is long alphanumeric (LA).
Descriptor Status	Indicates if the field is a descriptor, subdescriptor, superdescriptor, phonetic descriptor, hyperdescriptor, subfield, or superfield.
Field Type	Indicates if a field is a group (GR), multi-value (MU), or periodic group (PE). Multi-value fields and periodic groups are examples of multiply occurring fields.

Typically, an Adabas FDT contains some, but not all, of the field characteristics discussed above. To view the FDT, Software AG provides the ADAREP report. See your Software AG documentation for more information on how to run the ADAREP report.

The external field name is in the Predict dictionary.

External Field Name	32-byte name used in a Predict to identify the field. This name is unique to the file.

Reference: **Standard Formats for Adabas Fields**

The following table shows the acceptable standard formats for Adabas fields and their meanings.

Format	Description
A	Alphanumeric data field with a maximum of 253 bytes (126 for descriptor fields).
U	Zoned decimal data field with a maximum of 29 bytes (signed, unpacked data).
P	Signed packed decimal data field with a maximum of 15 bytes.
B	Unsigned binary data field with a maximum of 126 bytes.
F	Single-precision, floating point data field that is always four bytes long.
G	Decimal, double-precision integer field with an eight-byte maximum.

In the following example, the column on the left illustrates a partial Adabas FDT. The bold numbers on the left refer to the numbered annotations that follow:

```
   PAY-FILE

   FIELD DESCRIPTION (from FDT)          FIELD NAME (from DDM)

1. 01, PS, 08, P, NU, DE                 SSN
2. 01, PW, 04, P                         HOURLY_WAGE
3. 01, MI, PE                            MONTHLY_INFO
   02, MH, 04, P                         MONTHLY_HOURS
   02, MW, 04, P                         MONTHLY_WAGES
   02, MT, 04, P                         MONTHLY_TAX
4. 01, PT, 04, P, DE, MU                 TAX
   01, PC, 08, P, DE, MU                 CHILD_SSN
```

1. The first field, SSN, is an elementary-level field. Its internal name is PS, it is eight bytes long, and it is in packed decimal data format. The field is null suppressed, as indicated by the NU, and it is a descriptor (DE).

2. HOURLY_WAGE is also an elementary-level field. It is called PW internally, is four bytes long, and is also in packed decimal data format.
3. MONTHLY_HOURS, MONTHLY_WAGES, and MONTHLY_TAX are all subordinate fields of the MONTHLY_INFO periodic group (PE). Internally, they are called MH, MW, and MT, respectively. Each is four bytes long and is in packed decimal data format.
4. TAX and CHILD_SSN are elementary-level fields. TAX is called PT internally, is four bytes long, is in packed decimal data format, and is a multi-value (MU) field with a descriptor (DE) associated with it. CHILD_SSN is called PC internally, is eight bytes long, is in packed decimal format, and is also a multi-value field with a descriptor associated with it.

For more information about Adabas periodic groups (PE) and multi-value (MU) fields, see *Mapping Adabas Files With Variable-Length Records and Repeating Fields* on page 192.

Managing Data Storage With Null-Suppression

Null-suppression is one of the methods Adabas employs to manage data storage. Only the fields within a record that contain data are stored. Fields containing blanks for alphabetic characters or zeros for numeric data are not stored. They are represented by a one-byte "empty field" character. When a procedure accesses a record containing a null-suppressed field, Adabas expands the field to its full length and includes the null values of blanks or zeros.

When the null-suppressed field is a descriptor or part of a superdescriptor, no entry is made for the record containing that field in the inverted list. It would not be productive to have the inverted list direct you to records in which the descriptor has no data.

A field with null-suppression appears with the NU attribute in the Adabas FDT.

Note that for the Server to support NULL (MISSING = ON) for an Adabas field, you must define the field in the Adabas FDT with the NC attribute.

Managing Data Storage With SQL Null Options

Adabas includes two data definition options, Not Counted (NC) and Not Null or Null Value Not Allowed (NN), for providing SQL-compatible null representation for mainframe Adabas SQL Server (ESQ) by Software AG and other Structured Query Language (SQL) database query languages.

The NC and NN options cannot be applied to fields defined:

- With Adabas null suppression (NU).
- With a fixed-point data type (FI).
- With multiple-values (MU).
- Within a periodic group.

- As group fields.

NC: SQL Null Value Option

Without the Not Counted (NC) option, a null value is either zero or blank depending on the field format.

With the NC option, zeros or blanks specified in the record buffer are interpreted according to the "null indicator" value: either as true zeros or blanks (that is, as "significant" nulls) or as undefined values (that is, as true SQL or "insignificant" nulls).

If the field defined with the NC option has no value specified in the record buffer, the field value is always treated as an SQL null.

Note: On the mainframe platform, subdescriptors and superdescriptors defined with NC=YES and MISSING=ON parameters cannot be used to search for the SQL NULL value, as that causes an Adabas RC 61.

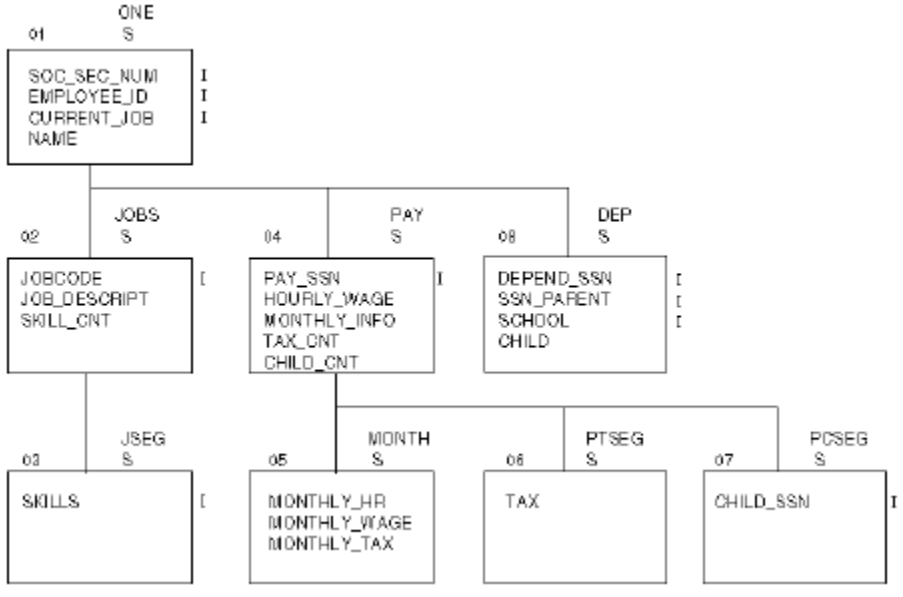
NN: SQL Not Null Option

The Not Null or Null Value Not Allowed (NN) option may only be specified when the NC option is also specified for a data field. The NN option indicates that an NC field must always have a value (including zero or blank) defined; it cannot contain "no value".

Server File Structure

The server uses a non-procedural language to create reports, graphs, and extract files. It also enables you to access data sources without knowing the details of the file structure or access method.

The server treats any data source as either a single-path or multi-path hierarchy. Graphically, information is laid out using an inverted tree structure, as in the following sample STAFF file. In the example, the letter I to the right of a field indicates an indexed field.



The most general information appears at the top, and the more specific information appears under it. Each box in the structure is referred to as a segment. A database can consist of one or more logically related segments.

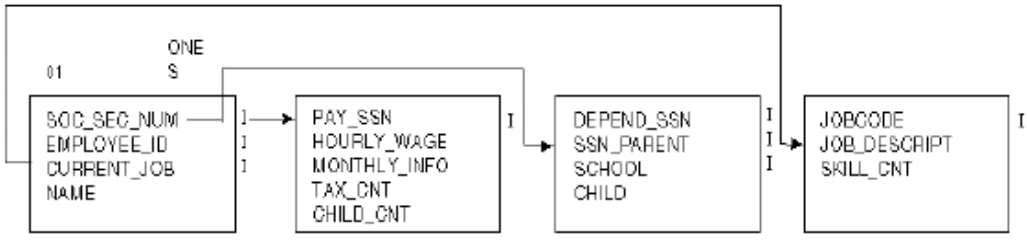
When logically related information is retrieved using this database structure, multiple occurrences of each segment are created. Each occurrence of a segment is called a segment instance. Each Adabas database is equivalent to a collection of logically related segment instances.

The retrieval sequence of the segments is determined by the view of the structure, that is, the order of the segments from top to bottom and left to right. The segment at the top is the parent, or root, segment. The segments under the parent are the child, or descendant, segments.

Generally, parent and child segments have a one-to-many relationship. That is, a single parent has multiple occurrences of one child segment. However, the server also handles one parent-one instance only of a child segment.

Adabas uses specific concepts and techniques for organizing data. It holds data in logically distinct files that are interrelated using fields that share common formats and values called descriptors.

Within a single Adabas file, records that contain multiple occurrences of a field can vary in length and format. The following example illustrates an Adabas structure containing four separate files that are linked by common fields:



Many Adabas structures are more complex than the preceding example.

Adabas Descriptors

Descriptors are fields, partial fields, or groups of complete and partial fields used by Adabas to select records in a file. Adabas descriptors correspond to indexed fields.

There are five types of descriptors supported by the Adapter for Adabas:

- Descriptors (DE), which have a value associated with a single field.
- Superdescriptors (SPR), which have a key value associated with all or part of two to twenty fields (see your Software AG documentation for current limitations on superdescriptors).
- Subdescriptors (NOP), which have a key value associated with part of a single field.
- Phonetic Descriptors (PDS), which have a similar phonetic value associated with a single field. The phonetic value of a descriptor is based on the first 20 bytes of the field value. Only alphabetic values are considered: numeric values, special characters, and blanks are ignored. Lowercase and uppercase alphanumeric characters are internally identical.
- Hyperdescriptors (HDS), which have a value generated, based on a user-supplied algorithm.

All five types of descriptors are collectively referred to as "descriptors."

Consider the Adabas FDT for the STAFF file:

```
STAFF
FILE FDT
    FIELD DESCRIPTION (from FDT)          FIELD NAME (from Predict)
       01, ES, 08, P, NU, DE              SOC_SEC_NUM
       01, EI, 06, A, NU, DE              EMPLOYEE_ID
       01, EJ, 03, A, DE                  CURRENT_JOB
       01, EN, 24, A                      NAME
```

Notice that SOC_SEC_NUM, EMPLOYEE_ID, and CURRENT_JOB are labeled as descriptors. Any one of these three fields can be used to search the STAFF file.

Adabas descriptors, superdescriptors, and subdescriptors must be declared in Master and Access Files in certain ways. For more information, see *Mapping Adabas Descriptors* on page 184.

Adabas Files With Fixed-Length Records

Unless an Adabas file has multi-value fields or periodic groups, each field occurs once in each record. When describing an Adabas file, you do not need to describe all the fields in your Master File; just the fields you use. Note that if you choose a periodic group, all fields in the periodic group must be defined. A single simple Adabas file maps to a single segment on the server, and each field you use in the Adabas file becomes a field in the segment.

Adabas RECORD		SEGMENT	
ES	SOC_SEC_NUM	SOC_SEC_NUM	ES
EI	EMPLOYEE_ID	EMPLOYEE_ID	EI
EJ	CURRENT_JOB	CURRENT_JOB	EJ
EN	NAME	NAME	EN

Adabas Files With Variable-Length Records and Repeating Fields

There are two types of Adabas repeating fields:

- Multi-value (MU) fields.
- Periodic (PE) groups.

An MU field is a single field that occurs a variable number of times in a record. It appears as type MU in an Adabas record description. Adabas supports up to 191 occurrences of MU fields per record.

A PE group is a group of contiguous fields that occur a variable number of times in a single record. It appears as type PE in an Adabas record description. Adabas supports up to 191 occurrences of PE fields per record. These component fields are regular fields or MU fields.

Note: The Adapter for Adabas supports the maximum number of occurrences of MU fields and PE groups allowed by Software AG.

When an Adabas file contains MU fields or PE groups, the repeating information occurs a variable number of times. The physical record length varies depending on how many times the repeating information actually appears.

More than one segment is needed to accurately describe an Adabas file with repeating data. The number of times the fields repeat is expressed in a counter field. For more information, see *Mapping Adabas Files With Variable-Length Records and Repeating Fields* on page 192.

Managing Adabas Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Adabas data types.

For the Adapter for Adabas to access Adabas files, you must describe each file you use in a Master and Access File. The logical description of an Adabas file is stored in a Master File, which describes the field layout.

Creating Synonyms

Synonyms define unique names (or aliases) for each Adabas table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File, which represent the server metadata.

The Create Synonym facility automatically generates Master and Access Files for Adabas files based on information stored in the Field Definition Table (FDT) in Adabas and the Predict dictionary (optionally). The command requires Adabas Release 5.0 or higher and Predict Release 3.1.4 or higher.

The syntax is identical on UNIX, Windows, and z/OS, and OpenVMS platforms.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Adabas

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Current DBID

Enter identification number of the database to access. (Required for all platforms.)

Associator data set name

Enter name of the Adabas Associator data set. (Required only for z/OS.)

Use Predict Metadata

Put a check mark in this checkbox to use metadata from an existing Predict file dictionary. This refreshes the pane, adding two entry boxes in which you can set the Default Predict Setting by entering the following:

`File Number`

Adabas file number where the Predict file is located.

`DBID`

Database ID (DBNO) for the Adabas DBMS containing the Predict dictionary data.

Then press *Select Tables* to summon the second Create Synonym pane (Step 2 of 2).

Provide values for the following superdescriptor processing parameters:

Mode

There are two options:

`Extended (NEW)`

Describes superdescriptors as groups in the Master File. Neither the groups nor their components (fields) have field names specified in the Master File. Aliases are populated using the Adabas FDT (2-byte name).

The Adapter for Adabas uses new logic to process the selection criteria of requests involving that synonym. Screening conditions within the request are analyzed and the superdescriptor that covers the highest order component fields required by the selection criteria are used. For more information, see *NEW Synonym Setting for Superdescriptors* on page 203.

Note that you must specify CALLTYPE=RL in the Access File in order to take advantage of superdescriptor-based access.

`Standard`

Incorporates the usual CREATE SYNONYM behavior, which does not trigger the new logic for requests using superdescriptors. Standard is the default value.

ISN field

No - Indicates that Adabas Internal Sequence Numbers (ISN) are not to be included in the Master File.

GFBID field

Global Format Buffer ID (GFBID) support is applicable only if a GFBID field is present in the Master File. This field has a user-defined field name, and an ALIAS of GFBID. This field is used to determine the Global Format Buffer ID that will be defined in read requests with identical field lists for the same database.

`Yes`

Specifies that a field generated in the Master File is to be used to specify Adabas Global Format Buffer ID values.

`No`

Indicates that Global Format Buffer ID values are not to be included in the Master File.

Enter the following additional parameters for synonym field name processing options:

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Adabas-specific Create Synonym Notes

- Only one Adabas file description can be generated in the Master File. If multiple Adabas files must be described in one Master File, a description for each Adabas file must be created and combined in one Master File manually.
- The Create Synonym facility describes Adabas files within the constraints of the Adapter for Adabas. For more information, see *Platform-Specific Functionality* on page 200. Superdescriptors, subdescriptors, periodic elements (PE groups), and multi-value fields (MU) are included. Comments are used to describe unsupported fields in the generated Master File.
- The Create Synonym facility allows you to customize the output using data from the Predict dictionary. You can:
  - Replace generic field names constructed based on Adabas field names (xx_FIELD) with the names obtained from the Predict dictionary.
  - Replace the USAGE format and length generated from an Adabas FDT (Field Definition Table) with the format and length from the Predict dictionary.

- Include the NATURAL column heading stored in the Predict dictionary in the Master File for use as the default column heading in server reports.

Example: **Creating Synonyms When Adabas Fields Are Defined With the NC Option**

The Create Synonym facility adds the parameter NC=YES in the Access File for fields defined with the NC option.

If a field with the NC option *does not have* the NN option, then the parameter MISSING=ON is also added to the field definition in the Master File. Subdescriptors and superdescriptors derived from this field will be defined as the fields with the following options: TYPE=NOP, NC=YES, and MISSING=ON. No component fields will be associated with these subdescriptors and superdescriptors.

Sample Master File and Access File contents with the NC option:

Master File:

```
FILENAME=ADANC1, SUFFIX=ADBSINX , $
  SEGMENT=S01, SEGTYPE=S0, $
    FIELDNAME=AA_FIELD, ALIAS=AA, USAGE=I6, ACTUAL=I2, FIELDTYPE=I, $
    FIELDNAME=AB_FIELD, ALIAS=AB, USAGE=I6, ACTUAL=I2, FIELDTYPE=I, MISSING=ON, $
    FIELDNAME=AC_FIELD, ALIAS=AC, USAGE=I6, ACTUAL=I2, FIELDTYPE=I, $
    FIELDNAME=AD_FIELD, ALIAS=AD, USAGE=I6, ACTUAL=I2, MISSING=ON, $
    FIELDNAME=AE_FIELD, ALIAS=AE, USAGE=I6, ACTUAL=I2, $
    FIELDNAME=BA_FIELD, ALIAS=BA, USAGE=A2, ACTUAL=A2, FIELDTYPE=I, $
    FIELDNAME=BB_FIELD, ALIAS=BB, USAGE=A2, ACTUAL=A2, FIELDTYPE=I, MISSING=ON, $
    FIELDNAME=BC_FIELD, ALIAS=BC, USAGE=A2, ACTUAL=A2, FIELDTYPE=I, $
    FIELDNAME=BD_FIELD, ALIAS=BD, USAGE=A2, ACTUAL=A2, MISSING=ON, $
    FIELDNAME=BE_FIELD, ALIAS=BE, USAGE=A2, ACTUAL=A2, $
   GROUP=G1_GROUP, ALIAS=G1, USAGE=A6, ACTUAL=A6, $
    FIELDNAME=CA_FIELD, ALIAS=CA, USAGE=A2, ACTUAL=A2, $
    FIELDNAME=CB_FIELD, ALIAS=CB, USAGE=A2, ACTUAL=A2, MISSING=ON, $
    FIELDNAME=CC_FIELD, ALIAS=CC, USAGE=A2, ACTUAL=A2, $
$ $$$$$$$$$$$$$$$$$$$$$ Superdescriptor $$$$$$$$$$$$$$$$$$$$$$$$$$$$$ $
    FIELDNAME=S1_FIELD, ALIAS=S1, USAGE=A6, ACTUAL=A6, FIELDTYPE=I, MISSING=ON, $
  $ FIELD=BA_FIELD_S01       ,ALIAS=BA         ,A2    ,A2    ,INDEX=I,$
  $ FIELD=BB_FIELD_S01       ,ALIAS=BB         ,A2    ,A2    ,INDEX=I,$
  $ FIELD=BE_FIELD_S01       ,ALIAS=BE         ,A2    ,A2    ,       ,$
$ $$$$$$$$$$$$$$$$$$$$$ Superdescriptor $$$$$$$$$$$$$$$$$$$$$$$$$$$$$ $
     FIELDNAME=S2_FIELD, ALIAS=S2, USAGE=A6, ACTUAL=A6, FIELDTYPE=I, MISSING=ON, $
$ FIELD=BA_FIELD_S02       ,ALIAS=BA         ,A2    ,A2    ,INDEX=I,$
$ FIELD=BC_FIELD_S02       ,ALIAS=BC         ,A2    ,A2    ,INDEX=I,$
$ FIELD=BD_FIELD_S02       ,ALIAS=BD         ,A2    ,A2    ,       ,$
$ $$$$$$$$$$$$$$$$$$$$$$$$ Subdescriptor $$$$$$$$$$$$$$$$$$$$$$$$$$$$ $
     FIELDNAME=S3_FIELD, ALIAS=S3, USAGE=A1, ACTUAL=A1, FIELDTYPE=I, MISSING=ON, $
$ $$$$$$$$$$$$$$$$$$$$$$$$ Subdescriptor $$$$$$$$$$$$$$$$$$$$$$$$$$$$ $
    FIELDNAME=S4_FIELD, ALIAS=S4, USAGE=A1, ACTUAL=A1, FIELDTYPE=I, $
$
```

Access File:

```
 RELEASE=6, OPEN=YES, $
 SEGNAM=S01, ACCESS=ADBS, FILENO=120, DBNO=3, CALLTYPE=FIND,
   UNQKEYNAME=AA_FIELD, WRITE=YES, $
$   CALLTYPE=RL  ,SEQFIELD=AA_FIELD                        ,$
$ FIELD=AA_FIELD ,TYPE=DSC       ,NC=   ,$
  FIELD=AB_FIELD, TYPE=DSC, NC=YES, $
  FIELD=AC_FIELD, TYPE=DSC, NC=YES, $
  FIELD=AD_FIELD, TYPE=, NC=YES, $
  FIELD=AE_FIELD, TYPE=, NC=YES, $
$ FIELD=BA_FIELD ,TYPE=DSC       ,NC=   ,$
  FIELD=BB_FIELD, TYPE=DSC, NC=YES, $
  FIELD=BC_FIELD, TYPE=DSC, NC=YES, $
  FIELD=BD_FIELD, TYPE=, NC=YES, $
  FIELD=BE_FIELD, TYPE=, NC=YES, $
  FIELD=CB_FIELD, TYPE=, NC=YES, $
  FIELD=CC_FIELD, TYPE=, NC=YES, $
  FIELD=S1_FIELD, TYPE=NOP, NC=YES, $
  FIELD=S2_FIELD, TYPE=NOP, NC=YES, $
  FIELD=S3_FIELD, TYPE=NOP, NC=YES, $
  FIELD=S4_FIELD, TYPE=NOP, NC=YES, $
```

Note: The following processing rules apply for fields defined with the NC=YES and MISSING=ON parameters:

- The default value is set to the SQL NULL value when a new record is created:

```
SQL
INSERT INTO ADANC1
   (AA_FIELD,   AB_FIELD,   AC_FIELD,
    BA_FIELD,   BC_FIELD,   BE_FIELD,
    CA_FIELD,   CC_FIELD)
    VALUES (21, 22, 23, 'B1', 'B3', 'B5','A2', 'C2');
END
```

- The value could be set to the SQL NULL value when a record is updated:

```
SQL
  UPDATE ADANC1 SET AB_FIELD=NULL
  WHERE  AA_FIELD = 21;
END
```

- These fields can be used in search criteria for selecting records that either *have or do not have* SQL NULL values, as in the following examples:

```
SQL
  SELECT AA_FIELD, AB_FIELD, AC_FIELD, AD_FIELD, AE_FIELD FROM ADANC1
  WHERE  AB_FIELD IS NULL AND AA_FIELD GE 10;
END

SQL
  SELECT AA_FIELD, AB_FIELD, AC_FIELD, AD_FIELD, AE_FIELD FROM ADANC1
  WHERE  AB_FIELD IS NOT NULL;
END

TABLE FILE ADANC1R
  PRINT AA_FIELD AB_FIELD AC_FIELD AD_FIELD AE_FIELD G1_GROUP
  WHERE AB_FIELD EQ MISSING;
END
```

- Subdescriptors and superdescriptors can be used only in search criteria. Their values cannot be reported. Here are several examples:

```
SQL
  SELECT AA_FIELD, AB_FIELD, AC_FIELD, AD_FIELD, AE_FIELD FROM ADANC1
  WHERE  S1_FIELD = 'A1A2A4' AND AA_FIELD > 10;
END

SQL
  SELECT AA_FIELD, AB_FIELD, AC_FIELD, AD_FIELD, AE_FIELD FROM ADANC1
  WHERE  S1_FIELD IS NOT NULL AND AA_FIELD > 10;
END
```

- On the mainframe platform, subdescriptors and superdescriptors defined with the NC=YES and MISSING=ON parameters cannot be used to search for an SQL NULL value, as that causes an Adabas RC 61.

Reference: **Master File Field Attributes**

The following field attributes describe Adabas data segments.

Field Attribute	Description
FILE	Master File name. It may or may not match the file name in the Adabas DBMS.
SUFFIX	Always ADBSINX.
SEGNAME	Segment names in the description generated by the Create Synonym facility. They follow a logical format to provide uniqueness within the file.
FIELD	Field name from the Predict dictionary (if used) or generated automatically (xx_FIELD).
GROUP	Identifies fields described as simple groups or PE groups. Is the field name from the Predict dictionary (if used) or generated automatically (xx_GROUP).
ALIAS	Actual Adabas short name. It can be detailed for counter fields without standard length. For order fields, it has the value ORDER.
USAGE	USAGE format and length of the field. This attribute determines how the value is displayed in reports. Values are determined based on ACTUAL format and length and then may be detailed by value from the Predict dictionary (if used). For fields without standard length, it has the maximum value for the format.
ACTUAL	Field standard format and length as stored in the Adabas Field Definition Table (FDT) for a given file. For fields without standard length, it has the maximum value for the format. For fields with format A and option LA (Long Alphanumeric, used only for z/OS) the ACTUAL length must have a value greater than 253. Value 500 is assumed.

Field Attribute	Description
INDEX=I	Indicates the field is a superdescriptor, subdescriptor, or simple descriptor.
TITLE	Column heading used in reports. This attribute is included only if the Predict dictionary is used and the field has a column heading value in the Predict dictionary.
GROUP	Identifies fields described as simple groups or PE groups.
$GRMU	Group that contains a PE group or an MU (multi-value) field.
$2LONG	Group field whose total length exceeds the maximum of 4096 characters supported by the server.
$PEMU	PE group that contains an MU (multi-value) field or is a group field that contains a PE group or an MU field. In both cases, the field cannot be used to retrieve data using the adapter.
$FIELD	Field that belongs to a commented group or superdescriptor composed of partial fields (NOP).

Reference: **Access File Attributes**

The following Access File attributes describe Adabas data segments:

Attribute	Description
RELEASE	Adabas release. If RELEASE is 5 or less, then FILENO can be 1–255 and DBNO can be 0–255. If RELEASE is 6 or greater, then the adapter supports two-byte FILENO (1–5000) and DBNO (1–65535).
OPEN	Determines whether the adapter should issue Adabas OPEN and CLOSE calls for each report request.
SEGNAM	Segment name as described in the Master File.

Attribute	Description
ACCESS	Access method for the segment. ADBS indicates segments that contain non-repeating data. PE indicates segments that describe periodic groups. MU indicates segments that describe multi-value fields.
DBNO	Adabas database number. On UNIX and Windows, and OpenVMS, this attribute must be included in the Access File. DBNO depends on RELEASE. If RELEASE is 5 or less, DBNO can be 0–255. If RELEASE is 6 or greater, DBNO can be 1–65535.
FILENO	Adabas file number. If RELEASE is 5 or less, FILENO can be 1–255. If RELEASE is 6 or greater, FILENO can be 1–5000.
CONNECTION	Is the parameterized form of the logical Connection Name defined in the adapter connection attributes. It is usually created as &&ADA_CONNECTION. It can be re-assigned in an a focexec through a -SET command. For example: `-SET &&ADA_CONNECTION=ADA814`
UNQKEYNAME	Field name that will be used as a unique key during file updating. The first unique indexed field from the root segment is used. If that does not exist, then a value from SEQFIELD is used.
CALLTYPE	FIND. Creates an additional commented line with CALLTYPE=RL if the Predict file view contains SEQFIELD data or the root segment contains an indexed field. The line with the preferable value of CALLTYPE can be chosen depending on the method used to retrieve the data from the database.
SEQFIELD	SEQFIELD name taken from the Predict file view, if used, or the first unique indexed field, or the first indexed field from Root segment. If CALLTYPE=FIND, then no value is entered for SEQFIELD in the Access File.
FIELD	Describes a descriptor, superdescriptor, subdescriptor, phonetic descriptor, hyperdescriptor, or a component of a superdescriptor.

Attribute	Description
TYPE	Type of descriptor for FIELD. Values are SPR for superdescriptors, NOP for subdescriptors or superdescriptors composed of partial fields, PDS for phonetic descriptors, HDS for hyperdescriptors, or DSC for a simple descriptor.
NU	Indicates if the field uses null suppression. Values are YES or NO.
NC	Specifies SQL null representation (NC stands for "not counted"). When on, forces the Create Synonym facility to insert "MISSING=ON" for this field in the associated MFD. NN option below further qualifies the SQL interpretation.
NN	NN "not null" or "null value not allowed" option indicates that an associated NC field must have a value (including zero or blank) defined; it cannot contain "no value.
PASS	Adabas password for the file. This attribute can be added manually.
KEYFLD	Only for child segments. This is the common field in the parent segment, which is used to relate the two files.
IXFLD	Only for child segments. This is the common field in the child segment, which is used to relate the two files.

Reference: **Comments in Master and Access Files**

The generated Master File and Access File contain several commented entries. They are provided for the client and are not used by the server. Comments are provided for the:

- CREATE SYNONYM time stamp and creator's User ID (included in both the Master and Access Files).
- Predict file name, file number, and DBID, if Predict is used.
- Headers before special fields: super/sub/hyper/phonetic descriptors or fields without standard length.
- Fields not supported by the adapter.

- Component fields of superdescriptors that are composed of partial fields (described as NOP type).

Reference: **Usage of Master File Fields With ISN Support**

The Adapter for Adabas can employ a data retrieval strategy through Read Logical by ISN (L1) calls. It can be used to determine the Internal Sequence Number (ISN) of a record that was read or that will be inserted into an Adabas file.

ISN-based access is applicable only if an ISN field is described in the Master File. This field has a field name that is user-defined and an ALIAS of ISN. The Usage format is I and the Actual format must be I4. This field can be defined only in segments that contain non-repeating data (that is, using an access method defined in the Access File as ADBS):

```
FIELD=ISN_FIELD, ALIAS=ISN, I10, I4, $
```

Equality tests on the ISN field can be used to retrieve a single record when the:

- Report request contains an equality operator in the selection test on an ISN list.

  or

- ISN field is used as the cross-referenced field in the Join to an Adabas file.

Adabas returns the Response Code 113 if the record with the ISN defined in the test is not present in the Address Converter for the file. The adapter returns the following message: "Record is not found".

The Adapter for Adabas uses Read Logical by ISN (L1) calls to retrieve all records for the entry segment when the:

- Report request does not contain optimizable selection criteria on an inverted list.
- Access File contains a SEQFIELD value for the segment whose value is equal to the ISN field name.

For example, the Access File ADATEST contains:

```
SEGNAM=S01, ACCESS=ADBS , ... ,SEQFIELD=ISN_FIELD ,$
```

Adabas returns each record in ascending order by the value of the ISN.

Example: **Equality Test on ISN Field**

```
SELECT AA_FIELD, AJ_FIELD FROM ADATEST
WHERE ISN_FIELD = 1100;
```

Note: Multifetch option will be suppressed for this call.

Read Logical by ISN (L1) calls to retrieve a subset of records for the entry segment when the:

- Report request contains the GE/GT relational operator in the selection test on an ISN list.
- Report request does not contain any selection tests on an inverted list.
- Access File contains a SEQFIELD value for that segment.

Example: Inequality Test on ISN Field

Access File ADATEST contains:

```
SEGNAM=S01, ACCESS=ADBS, ... ,SEQFIELD=AA_FIELD ,$
```

Read Logical by ISN (L1) is used:

```
SELECT AA_FIELD, AE_FIELD FROM ADATEST
WHERE ISN_FIELD > 1100;
```

Reference: ISN for Insert

After issuing an Insert request on a file with an ISN field in the Master File, the resulting ISN generated by Adabas is displayed by the message FOC4592:

```
(FOC4592) RECORD IS INSERTED WITH ISN : nnnnn
```

Example: Issuing an Insert Request

```
SQL
 INSERT INTO ADBTEST (AA_FIELD, AJ_FIELD)
VALUES ('11111111', 'TAMPA');
END

ADBTEST ADBSINX ON 09/20/2002 AT 15.22.16
(FOC4592) RECORD IS INSERTED WITH ISN : 11
(FOC4566) RECORDS AFFECTED DURING CURRENT REQUEST : 1/INSERT

TRANSACTIONS: TOTAL = 1 ACCEPTED= 1 REJECTED= 0
SEGMENTS: INPUT = 1 UPDATED = 0 DELETED = 0
```

You can assign a value for the ISN field if the Insert request contains the ISN field and the assigned value is not 0.

The adapter will issue an Adabas N2 Direct Call to assign this ISN value to the inserted record. Adabas returns Response Code 113 if this value was already assigned to another record in the file or if it is larger than the MAXISN in effect for the file.

Reference: **Master File Fields and GFBID Support**

The Adapter for Adabas can optimize the performance of queries that use the same Adabas field lists repeatedly. Field lists are generated in Adabas format buffers, and can be retained.

Global Format Buffer ID (GFBID) support is applicable only if a GFBID field is present in the Master File. This field has a user-defined field name, and an ALIAS of GFBID. This field is used to determine the Global Format Buffer ID that will be defined in read requests with identical field lists for the same database. The GFBID field has a USAGE format of A8 and an ACTUAL format of A8. This field can be defined only in segments that contain non-repeating data (that is, the access method defined in the Access File is ADBS).

Example: **Using GFBID Syntax in a Master File**

```
FIELD=GID_FIELD, ALIAS=GFBID, A8, A8, $
```

Note:

- If the field list is changed but the same GFBID is used in a request, then incorrect results may be displayed. In some cases, a message about the possible mismatch between the Field Definition Table (FDT) and Master File will be issued.
- If two requests have the same list of selected fields but different fields are used in selection criteria, then the requests must use different GFBID values.

The GFBID field can be defined in the Master File manually or using the Create Synonym facility with option PARMS GFBID.

Reference: **Using the GFBID Parameter With the Create Synonym Facility**

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

The value of GFBID can have up to 8 bytes and must start with a digit or uppercase character.

If GFBID is used in a request against a file that contains simple PE/MU segments, it will be applied to Adabas calls to get the field values from these segments. The GFBID value will be adjusted for each non-ADBS segment, that is, a segment number will be placed in the last (8th) byte of the GFBID field.

Calls to a PE (periodic element) with MU (multi-value) child or an MU with PE parent segment will not use GFBID values.

Note: To make the GFBID value unique within Adabas, do not use 8 byte GFBID values for these types of calls.

- If a GFBID field is defined in the Master File, it can be used in a request as part of the selection test. The adapter will take the GFBID value from the selection criteria, deactivate the field, and remove it from the match array. The GFBID value is placed in the ADD5 field of the Adabas Control Block for the request.
- If the GFBID is applied to an Adabas call, then field name ADD5 appears in the adapter trace. GFBID values that were issued in all requests to the database are accumulated in the Adabas internal queue. These values can be removed from the queue by issuing the following adapter SET command:

  ```
  ENGINE ADBSINX SET GFBID_OFF ALL/<value> DBID <number>
  ```

When a single <value> is in the SET command, all values issued for child segments are removed as well. If <value> contains blanks, then value must be enclosed in single quotation marks.

ALL clears all GFBID values.

Example: **Using GFBID Syntax**

Master File ADATEST contains:

```
FIELD=GID_FIELD, ALIAS=GFBID, A8, A8, $
```

Request 1. Global ID = ABC1:

```
SQL
SELECT AA_FIELD, AJ_FIELD, ISN_FIELD, AQ0201_OCC, AR_FIELD, AS_FIELD,
AT_FIELD
FROM EMPLOYEES
WHERE ISN_FIELD > 1100 AND GID_FIELD = 'ABC1';
END
```

Result:

```
PAGE 1

 AA_FIELD AJ_FIELD     ISN_FIELD AQ0201_OCC AR_FIELD AS_FIELD AT_FIELD
 -------- --------     --------- ---------- -------- -------- --------

 NUMBER OF RECORDS IN TABLE= 7 LINES= 7
```

Request 2. Global ID = ABC1, but field's list is changed:

```
SQL
SELECT AA_FIELD, ISN_FIELD, AQ0201_OCC, AR_FIELD, AS_FIELD, AT_FIELD
FROM EMPLOYEES
WHERE ISN_FIELD > 1100 AND GID_FIELD = 'ABC1';
END
```

Result:

```
(FOC4567) POSSIBLE MISMATCH BETWEEN FDT AND MFD : file=19879548
(FOC4591) ERROR RETURN ON READ BY ISN : S01 /999:ffffffcd001d00

 NUMBER OF RECORDS IN TABLE= 0 LINES= 0
```

Request 3. Remove value 'ABC1' from Adabas:

```
ENGINE ADBSINX SET GFBID_OFF ABC1 DBID 3
```

Request 4. Repeat request 2.

```
SQL
SELECT AA_FIELD, ISN_FIELD, AQ0201_OCC, AR_FIELD, AS_FIELD, AT_FIELD
FROM EMPLOYEES
WHERE ISN_FIELD > 1100 AND GID_FIELD = 'ABC1';
END
```

Result:

```
PAGE 1

 AA_FIELD ISN_FIELD AQ0201_OCC AR_FIELD AS_FIELD AT_FIELD
 -------- --------- ---------- -------- -------- --------
 30034517 1105      1          UKL      6500     750

 NUMBER OF RECORDS IN TABLE= 7 LINES= 7
```

Request 5. Remove all GFBID values for Database 3 from Adabas:

```
ENGINE ADBSINX SET GFBID_OFF ALL DBID 3
```

Overview of Master and Access Files

The server processes a report request with the following steps:

1. It locates the Master File for the Adabas file. The file name in the report request is the same as the z/OS PDS member name.
2. It detects the SUFFIX attribute, ADBSINX, in the Master File. Since this value indicates that the data resides in an Adabas file, it passes control to the adapter.
3. The adapter locates the corresponding Access File and uses the information contained in both the Master and Access Files to generate the Adabas direct calls required by the report request. It passes these direct calls to the Adabas DBMS.
4. The adapter retrieves the data generated by the Adabas DBMS and returns control to the server. For some operations, the server may perform additional processing on the returned data.
5. Beginning with Version 7 Release 7.4 of the server, the same adapter supports access to the database with different SVCs through different connections (see Connection Name in *Connection Attributes for Adabas* on page 132).

   The CREATE SYNONYM facility will place the FILENO, DBNO, and CONNECTION Access File attributes in parameterized form with default values that were provided when the synonym was created.

   These values can be changed later with a FOCEXEC by using a -SET command. For example:

   ```
   -SET &&ADA_CONNECTION=ADA814;
   -SET &&ADA_DBNO=123;
   -SET &&ADA_FILNO=1234;
   ```

Access and Master Files created in previous versions can be used without any changes, except in the case where legacy files are going to be used to access Adabas databases with different SVCs . In those cases, the new CONNECTION attribute has to be placed into the old Access File, as shown in example above and the value of &&ADA_CONNECTION must correspond to the Connection Name from the connection string in server profile.

If CONNECTION is not found among the connection strings, the adapter will issue error message FOC4515.

Master Files for Adabas

Standard Master File attributes are generally used to describe Adabas files, but there are concepts in Adabas file processing that require special terminology at the field and segment level. On z/OS, the Master File is a member of a PDS allocated to DDNAME MASTER.

The server permits a great deal of flexibility in its Master Files. For the Adapter for Adabas, you need to describe only the Adabas fields actually used in reporting applications, omitting any unnecessary Adabas fields. (Note the exception that if a PE group is included in the Master File, all fields of the PE group must be included. See *Field Attributes in Master Files* on page 170 and *Describing Multi-Value Fields Within Periodic Groups* on page 197 for additional information.) Additionally, describing the same Adabas file in multiple ways enables you to access that same file in its different configurations within one procedure.

Master Files have three parts: file declaration, segment declaration, and field declaration, each of which is explained in these topics. Concepts that are specific to Adabas files, for which the server requires unique syntax in the Master File, are also explained.

The following is an example of the Master File for VEHICLES.

```
$$$ CREATED ON 12/10/03 AT 10.17.27 BY PMSMJB
FILENAME=ADACAR,SUFFIX=ADBSINX,$

$ ADABAS FILE = VEHICLES-FILE                      DICTIONARY = 6
SEGNAME=S01     ,SEGTYPE=S,$
 FIELD=REG_NUM                    ,ALIAS=AA     ,A15   ,A15  ,INDEX=I,$

SEGNAME=AM0101  ,SEGTYPE=S,PARENT=S01  ,OCCURS=AMC,$  MAX= 60
 FIELD=MAINT_COST                 ,ALIAS=AM     ,P7    ,P4   ,$
 FIELD=AM0101_OCC                 ,ALIAS=ORDER  ,I4    ,I2   ,$
```

File Attributes in Master Files

Master Files begin with a file declaration that names the file and describes the type of data source. The file declaration has two attributes, FILENAME and SUFFIX.

The syntax is

```
FILE[NAME]=filename, SUFFIX=ADBSINX [,$]
```

where:

filename

Is a one- to eight-character name that complies with server file naming conventions.

ADBSINX

Is the value that specifies the Adapter for Adabas.

FILENAME

The FILENAME (or FILE) is any valid name from one to eight characters long.

In the z/OS environment, it is a member of a partitioned data set allocated to the DDNAME MASTER.

SUFFIX

The value for the SUFFIX attribute is always ADBSINX, which is the name of the Adapter for Adabas program that the server loads to read an Adabas database.

Example: **File Declaration**

The following example is a typical file declaration:

```
FILENAME=ADACAR, SUFFIX=ADBSINX,$
```

Segment Attributes in Master Files

Each segment declaration describes one Adabas record or a subset of an Adabas record (called a logical record type). Each logical record type described in a Master File requires a segment declaration that consists of at least two attributes, SEGNAME and SEGTYPE.

The syntax is

```
SEGNAME=segname, SEGTYPE=segtype [,PARENT=parent]
                                 [,OCCURS=occursname][,$]
```

where:

segname

Is a unique one- to eight-character name that identifies the segment.

segtype

Identifies the characteristics of the segment. Possible values are:

S which indicates multiple instances of a descendant segment are related to a given parent.

SO which indicates the Write Adapter for Adabas (for the Read Adapter for Adabas, SEGTYPE=S is sufficient).

U which indicates a single instance of data for a descendant segment is related to its parent.

KL which indicates multiple instances of a cross-referenced descendant segment are related to a given parent.

KLU which indicates a single instance of a cross-referenced descendant segment is related to its parent.

parent

Is the name of the parent segment in the Master File.

occursname

Indicates a data field in the parent segment that contains the number of occurrences of the descendant segment. Its value is derived from the two-character internal Adabas name (ALIAS field on the server) appended with the letter C.

SEGNAME

The SEGNAME (or SEGMENT) attribute is the name of a group of data fields that have a one-to-one relationship to each other in the Adabas file.

You may describe an Adabas file in the server hierarchical design to take advantage of multi-value fields and periodic groups. You may have multiple Adabas records described in the same Master File view. Each record is described as a segment with a unique SEGNAME.

Syntax: How to Name a Root Segment in the Master File

For the root segment of the Adabas file, the segment name generated is

S*nn*

where:

nn

Is a two-digit number indicating the order in which the file was selected.

The first file (selected as the root from the File Selection Menu) has SEGNAME=S01. Subsequent files used in the same description (selected as children from the File Selection Menu) have SEGNAME=S02, SEGNAME=S03, and so on.

Syntax: How to Name a Segment for a PE Group and MU Field

The segment names for PE (periodic element) groups and MU (multi-value) fields have the format

aammnn

where:

aa

Is the Adabas field name.

mm

Is a two-digit number that indicates the order in which the PE group or MU field appears in the PREDICT description of the file.

nn

Is the order number used for the root segment.

Example: **Naming a Segment for a PE Group and MU Field**

Using the syntax aammnn, SEGNAME=BE0201 describes the segment for the field BE, which is the second (02) PE group or MU field described in the first segment (01).

SEGTYPE

The SEGTYPE attribute identifies the basic characteristics of related or cross-referenced segments. Cross-referencing is a method of accessing information from two or more different files or segments to use in a single report request.

SEGTYPE

Is the root segment and cross-reference segment type. The SEGTYPE is S0 for the root file and children with a non-unique IXFLD. The SEGTYPE is U for a child with a unique IXFLD. The SEGTYPE for all PE and MU fields is S0.

PARENT

Any segment except the root is a descendant, or child, of another segment. The PARENT attribute supplies the name of the segment which is the logical parent or owner of the current segment. If no PARENT attribute appears, the default is the immediately preceding segment. However, it is highly recommended to include the parent. The PARENT name is the one- to eight-character SEGNAME of a previous segment.

PARENT

Is the value of SEGNAME of the parent record.

OCCURS

For more information on the segment attribute OCCURS, which applies to repeating fields and groups, see *Describing Multi-Value Fields and Periodic Groups With the OCCURS Attribute* on page 195.

OCCURS

Indicates the number of occurrences of a PE group or MU field. This attribute contains the Adabas field name of the PE group or MU field with the suffix C, which is the ALIAS of the counter field in the parent segment.

Example: Segment Declaration

The following two examples are typical segment declarations:

```
SEGNAME=S01         ,SEGTYPE=S      ,$
SEGNAME=AM0101      ,SEGTYPE=S      ,PARENT=S01     ,OCCURS=AMC    ,$
```

Field Attributes in Master Files

Field declarations describe the fields in each file. For the simplest file structures (single-segment, fixed-length files), you need to describe only the Adabas fields you actually use for reporting purposes.

Put the fields in any order within their segment, except in the case of fields within periodic groups (PE). The PE group must have all fields defined and in the proper order.

The syntax is

```
FIELD[NAME]=fieldname, ALIAS=alias, [USAGE=]display, [ACTUAL=]format,$
```

where:

fieldname

Is the 1- to 66-character name that is unique to the Master File.

alias

Is the two-character internal Adabas field name.

display

Is the server display format for the field.

format

Is the server definition of the Adabas field format and length.

Note: Field declarations are always terminated with ,$.

There are additional attributes that apply to superdescriptor, cross-referenced, repeating, and other types of fields.

FIELDNAME

The field name appears as a column heading when you include the field in a report request. You can change the default by using AS or NOPRINT in the report or by using TITLE in the Master File.

Field names are unique names of up to 66 characters. The Master File field name does not need to be the same as the Adabas field name. Field names can include any alphanumeric characters, but the first character must be a letter from A to Z. Avoid embedded blanks and special characters.

Since all references to data on the server are through field names or aliases, the field names should be unique within a Master File. This requirement is true even when the same Adabas record is included as two differently structured segments in the same Master File. You must specify different field names in the two segments or the server uses the first one in the Master File unless you qualify which field you want, for example, file.field, segment.field.

ALIAS

The ALIAS for a single Adabas field *must* contain the two-character internal Adabas field name. The adapter uses it to generate direct calls to the Adabas DBMS. The format rules are as follows:

- The ALIAS equals the two-character internal Adabas field name, for example, AM.
- The letter C is appended to the two-character internal Adabas field name if the field is the counter field for a PE group or MU field, for example, AMC.
- The ALIAS is the two-character internal Adabas field name appended with the digit 1 if an application calls for only the first occurrence of a repeating field, for example, AM1.
- The ALIAS can be used to reformat the length of the Adabas field. See *Using the ALIAS to Reformat Adabas Fields* on page 171 for examples using the reformatting option.

Note: Because of the requirement that the ALIAS in a Master File be the same as the two-character internal Adabas field name, your Master File may include duplicate ALIAS values. In that case, the field name is used to differentiate between the segments.

Using the ALIAS to Reformat Adabas Fields

The ALIAS field allows reformatting of the field for a different view. Several Adabas data formats have lengths that exceed the supported maximum length of data formats on the server. You can use the ALIAS to convert this data to an acceptable ACTUAL format and length.

When a field is specified in a retrieval request, the value in the ALIAS is passed to Adabas in the Format buffer. Adabas uses the ALIAS to process the field and return the data to the server.

To use the reformatting option, define the ALIAS using length and format values that indicate how you want to reformat the field.

The syntax is

```
ALIAS='xx,l,f'
```

where:

xx

Is the two-character internal Adabas field name.

l

Is the new length of the field value in number of bytes.

f

Is the new Adabas format of the field value.

The entire value must be enclosed in single quotation marks.

For example, if you want to use only the first three characters in a six-byte field, use the following syntax in your Master File:

```
FIELD=L_DBNR, ALIAS='AU,3,P', USAGE=P3, ACTUAL=P3  ,$
```

In this case, the Adapter for Adabas will read only the first three bytes (L_DBNR is a six-byte field with the Adabas description: 01, AU, 6, U).

In the next example, to convert an Adabas binary field format of ten bytes (Adabas description: 01, BB, 10, B) to an alphanumeric format large enough to accommodate the Adabas value, you could use the following syntax in your Master File:

```
FIELD=TESTFLD, ALIAS='BB,10,A', USAGE=A20, ACTUAL=A10  ,$
```

Notice that you must also change the USAGE and ACTUAL values to reflect the changes in the format. Refer to the chart in *ACTUAL* on page 173 for the acceptable USAGE and ACTUAL values along with the corresponding Adabas codes.

Note: Groups cannot be reformatted. This formatting is valid only for elementary fields.

USAGE

The USAGE attribute enables you to describe how you want fields displayed on the screen, printed in reports, or used in calculations. This attribute includes the data field type, length, and any applicable display options when the field values are printed. FORMAT is a synonym for USAGE.

The syntax is

```
USAGE=tllleeeee
```

where:

t

Is the field type.

lll

Is the number of positions needed to display the field.

eeeee

Are the display options.

The value that you specify for field length is the number of alphanumeric characters or numeric digits that the server allocates for the field in any display or report. The specified value excludes the editing characters, such as comma, $, and so on. Display options control how a field value is printed.

ACTUAL

The ACTUAL attribute describes the length and type of the Adabas field in storage. It is used to describe the format of fields from external data files only, and must be included in the Master Files needed for the Adapter for Adabas. The source of this information is your existing Adabas Field Definition Table (FDT).

The syntax is

ACTUAL=*tlll*

where:

t

Is the server field type of the Adabas field.

lll

Is the storage length of the Adabas field.

The server permits the following conversions from ACTUAL format to USAGE (display) format:

Adabas Format Type	Server ACTUAL Type	Server ACTUAL Length*	Server USAGE Type	Server USAGE Length*	Description
A	A	1-256	A	1-256	Alphanumeric

Adabas Format Type	Server ACTUAL Type	Server ACTUAL Length*	Server USAGE Type	Server USAGE Length*	Description
G	F D	4 8	F D	1-9 1-15	Float Single-Precision Float Double-Precision
F	I	2, 4	I	1-9	Integer
B 1-4 5-6 7-126	 I P A	 1-4 7-8 9-126	 I P A	 1-9 12-15 14-252	 Integer Values Packed Decimal Alpha
P	P	1-15	P	1-33.*n*	Packed Decimal
U	Z	1-29	A or P	1-33.*n*	Zoned

* Lengths are measured as follows:

- ACTUAL is in number of bytes.
- USAGE allows space for all possible digits, a minus sign for negative numbers, and a decimal point in numbers with decimal digits.

The following table shows the codes for the types of data the server reads:

ACTUAL Type	Description
A*n*	Alphanumeric characters A to Z, 0 to 9, and the special characters in the EBCDIC display mode, where *n* = 1 to 256 bytes.
D8	Double-precision, floating-point numbers, stored internally in eight bytes.
F4	Single-precision, floating-point numbers, stored internally in four bytes.
I*n*	Binary integers, where *n* = 1 to 4.
P*n*	Packed decimal data, where *n* = 1 to 15 bytes.

ACTUAL Type	Description
Z*n*	Zoned decimal data, where *n* = 1 to 30 bytes. Represent the field as Z*m.n*, where *m* is the total number of digits, and *n* is the number of decimal places (for example, Z6.1 means a six-digit number with one decimal place).

INDEX

For more information on the field attribute INDEX, which applies to descriptors, see *Specifying INDEX=I* on page 184.

GROUP

For more information on the field attribute GROUP, which applies to superdescriptors, see *Specifying Superdescriptors Using the GROUP Attribute* on page 185.

Example: **Field Declaration**

The following is a typical field declaration:

```
FIELD=MODEL ,ALIAS=AE ,USAGE=A20 ,ACTUAL=A20 ,$
```

Access Files for Adabas

An Access File describes the physical attributes of the Adabas file, such as the database number, file number, descriptors, and security. See *Overview of Master and Access Files* on page 164 for more information about Master and Access Files.

Access Files store database access information used to translate report requests into the required Adabas direct calls.

In the z/OS environment, the Access File is located in a PDS allocated to the DDNAME ACCESS. Each member is a separate Access File.

An Access File consists of 80-character records in comma-delimited format. A record in an Access File contains a list of attributes and values, separated by commas and terminated with a comma and dollar sign (,$). This list is free-form and spans several lines if necessary. You can specify attributes in any order.

The server reads blank lines, and lines starting with a dollar sign in column one, as comments.

Every Access File contains a release declaration and at least one segment declaration. Release declarations and segment declarations each have their own set of attributes. These attributes are discussed in the following topics.

The following is a sample Access File:

```
$$$ FILENAME=EMPFILE1,SUFFIX=ADBSINX,$
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = EMPLOYEES                          DICTIONARY =
SEGNAM=S01   ,ACCESS=ADBS,FILENO=001,DBNO=1,CALLTYPE=RL,
              SEQFIELD=PERSONNEL_ID,$
FIELD=DEPT_PERSON                          ,TYPE=SPR,$
FIELD=DEPT                                 ,TYPE=DSC,NU=YES,$
FIELD=NAME                                 ,TYPE=   ,NU=NO,$
 FIELD=LEAVE_LEFT                          ,TYPE=SPR,$
 FIELD=LEAVE_DUE                           ,TYPE=   ,NU=YES,$
 FIELD=LEAVE_TAKEN                         ,TYPE=   ,NU=YES,$
FIELD=DEPARTMENT                           ,TYPE=NOP,NU=NO,$
SEGNAM=AI0101,ACCESS=MU  ,FILENO=001,$ ADDRESS_LINE
SEGNAM=AQ0201,ACCESS=PE  ,FILENO=001,DBNO=1,$ INCOME
SEGNAM=AT0301,ACCESS=MU  ,FILENO=001,DBNO=1,$ BONUS
SEGNAM=AW0401,ACCESS=PE  ,FILENO=001,$ LEAVE_BOOKED
SEGNAM=AZ0501,ACCESS=MU  ,FILENO=001,$ LANG
```

Release Declaration

The release declaration must be the first uncommented line of the Access File. It identifies the release of Adabas and indicates whether the Adapter for Adabas issues Adabas OPEN and CLOSE calls for each report request.

The syntax is

```
RELEASE=relnum [,OPEN={YES|NO}] ,$
```

where:

relnum

Is the Adabas release number.

OPEN

Specifies whether the adapter issues Adabas OPEN and CLOSE calls to Adabas in each report request. Possible values are:

YES which indicates that Adabas OPEN and CLOSE calls are issued. YES is the default value.

NO which indicates that Adabas OPEN and CLOSE calls are not issued.

RELEASE

The first declaration in the Access File contains the Adabas release number with the attribute RELEASE. Specify the full release number. The value is for documentation only.

The following example illustrates the use of the RELEASE attribute to specify the Adabas release number:

```
RELEASE=6 ,$
```

OPEN

The OPEN attribute specifies whether the Adapter for Adabas issues Adabas OPEN and CLOSE calls to Adabas in each report request. Specifying YES or NO achieves the following results:

Value	Result
YES	The adapter issues an OPEN call to Adabas at the start of a call set initiated by a retrieval request. An Adabas CLOSE is issued at the end of retrieval for the request. YES is the default value. `RELEASE=6 , OPEN=YES ,$`
NO	Adabas OPEN and CLOSE calls are not issued for any retrieval request. `RELEASE=4.1, OPEN=NO ,$`

Accept the default value (YES) unless you are using an Adabas release lower than 5.0.

Note: To reduce overhead incurred in opening and closing databases when processing requests from multiple agents, the Adapter for Adabas allows opened databases to remain open until one of the following actions occurs:

- A request changes the database, the file, the database mode (close) or its access mode (read/write).
- The last agent disconnects.
- The last open database is closed explicitly.

Segment Attributes in Access Files

Segment declarations contain detailed information about each segment of an Adabas file. The segment declaration attributes specify the segment name, the file and database numbers, and the Adabas password, as well as retrieval options.

The syntax is

```
SEGNAM=segname, ACCESS=access, FILENO=file_number [,DBNO=database_number]
[,CALLTYPE={FIND|RL}] [,USE={FIND|ANY}] [,SEQFIELD=seqfield] [,PASS=password]
[,FETCH={ON|OFF}] [,FETCHSIZE={n|MAX}] [,UNQKEYNAME=unique_field] [,WRITE=YES|NO],$
```

where:

segname

Is the SEGNAME value from the Master File.

access

Specifies the segment type that the adapter uses for each segment. Possible values are:

ADBS which is for a segment that contains only non-repeating fields. ADBS is the default value.

PE which is for a segment that is a periodic group in the same file as the parent segment.

MU which is for a segment that is a multi-value field in the same file as the parent segment.

file_number

Is the number that identifies an Adabas file.

database_number

Is the number that identifies an Adabas database.

CALLTYPE

Indicates the type of data retrieval call constructed by the adapter. Possible values are:

FIND in which a FIND call is issued when there are one or more WHERE or IF statements in a retrieval request detected against fields defined with INDEX=I. FIND is the default value.

RL in which a Read Logical (RL) call is issued when there are one or more WHERE or IF statements against fields defined with INDEX=I.

Note: See your database administrator for the most efficient CALLTYPE to be used at your site.

USE

Indicates a method for handling unreadable sub or superdescriptor fields that are derived from PE or MU access types and defined in the root segment. Possible values are:

FIND indicates that the S1 command will be issued against such a field even if CALLTYPE is RL.

ANY indicates that fields are not of the sub/superdescriptor types. ANY, or the absence of a USE= entry, are the default values.

seqfield

Provides a default index which controls Read Logical (RL) retrieval when there is no IF or WHERE selection test.

password

Is the Adabas password for the file.

FETCH

Indicates whether to use the Fetch feature. Possible values are:

ON which sets the Fetch feature on for the user session. ON is the default value.

OFF which sets the Fetch feature off for the user session.

If you include this attribute, you must also include FETCHSIZE (see below).

FETCHSIZE

Sets the number of records per buffer. Possible values are:

n which is the number of records per buffer (1 to 32K). 10 is the default value.

MAX which is automatically calculated by the adapter to allow the maximum number of records that fit in a 32K buffer.

UNQKEYNAME

Is the attribute that indicates the unique key. It does not necessarily define the key described in the ADABAS FDT with the UQ option.

WRITE

Is the attribute that indicates the WRITE capability. NO is the default value.

Note: FETCH and FETCHSIZE are applicable only to segments described as ACCESS=ADBS. FETCH and FETCHSIZE can be set dynamically to override the Access File settings.

Special attributes that apply to embedded JOINs are explained in *Implementing Embedded JOINs: KEYFLD and IXFLD* on page 190. Attributes that apply to superdescriptors and subdescriptors are explained in *Customizing the Adabas Environment* on page 201.

SEGNAM

The SEGNAM attribute specifies the name of the segment being described. It is the same name as the SEGMENT value in the Master File.

ACCESS

The ACCESS attribute specifies the segment type that the Adapter for Adabas uses for each segment. The values are:

- ADBS, which specifies a segment that contains only non-repeating fields. ADBS is the default value.
- PE, which specifies a segment that is a periodic group in the same file as the parent segment.
- MU, which specifies a segment that is a multi-value field in the same file as the parent segment.

All three access values use the attributes FILENO and DBNO, as shown in this partial Access File for EMPLOYEES with the specification of PE and MU fields.

```
$$$ FILENAME=EMPFILE1,SUFFIX=ADBSINX,$
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = EMPLOYEES                          DICTIONARY =
SEGNAM=S01    ,ACCESS=ADBS,FILENO=001,DBNO=1,CALLTYPE=RL,
               SEQFIELD=PERSONNEL_ID,$
SEGNAM=AQ0201,ACCESS=PE   ,FILENO=001,DBNO=1,$ INCOME
SEGNAM=AT0301,ACCESS=MU   ,FILENO=001,DBNO=1,$ BONUS
SEGNAM=AW0401,ACCESS=PE   ,FILENO=001,DBNO=1,$ LEAVE_BOOKED
```

ACCESS=ADBS

ACCESS=ADBS specifies the main segment of the file. This segment contains only non-repeating fields.

FILENO

The FILENO attribute specifies the Adabas file number. You need this file number to identify the Adabas file(s) you wish to access. The valid values are 1 to 255 (5000 is the maximum value for a mainframe platform). The FILENO attribute has to be defined for segments with ACCESS=ADBS. If the FILENO attribute is omitted for segments with ACCESS=MU/PE, then it will be taken from the corresponding parent segment.

Suppose you are accessing two segments: the first is in the EMPLOYEE file, and the second is in the INSURANCE file. To describe this situation in the Access File, use the SEGNAM and FILENO attributes as illustrated in *DBNO* on page 181.

DBNO

The DBNO attribute specifies the Adabas database number. It is used when you define files from multiple databases in one Master File. If it is not provided, the DBNO will be read from the DDCARD (on a mainframe platform only). If the DDCARD is not allocated, the adapter uses the default value, DBNO=0.

If the DBNO attribute is omitted for a segment with ACCESS=PE/MU, it will be taken from the corresponding parent segment. The DBNO attribute has to be defined for segments with ACCESS=ADBS on non-mainframe platforms.

The following example illustrates the use of both the FILENO and DBNO attributes to account for the files being in different databases:

```
SEGNAM=ONE   ,FILENO=1  ,DBNO=1 ,... ,$
SEGNAM=PAY   ,FILENO=2  ,DBNO=3 ,... ,$
```

CALLTYPE

The CALLTYPE attribute affects how the Adapter for Adabas processes WHERE and IF statements on descriptors in report requests and how it retrieves cross-referenced file data from a descendant segment. With CALLTYPE, you optionally specify the type of access to use in order to process the inverted lists for any given segment. Ask your Adabas database administrator to advise you when you are selecting a CALLTYPE.

The possible values are:

FIND

An Adabas FIND call is issued when there are one or more WHERE or IF statements against fields defined to the server with INDEX=I. The search is on specific values of the field.

The Adapter for Adabas can generate Adabas FIND (S1) calls even when non-descriptor fields are used as search criteria. This can occur whenever CALLTYPE=FIND is specified in the Access File, and if you include an IF or WHERE test when referencing a non-descriptor field in your TABLE or TABLEF request.

To turn off this feature, see the topic in *Adapter Navigation* on page 227 that discusses the optimization of the FIND call using non-descriptor fields.

RL

An Adabas Read Logical call is issued when there are one or more WHERE or IF statements against fields defined to the server with INDEX=I.

Note: If you have selected a field defined with TYPE=NOP (for example, subdescriptors), a FIND call is issued even if RL has been specified in cases when:

- SET NOPACCESS FIND was performed.
- The server is running in OpenVMS environment.
- The same Adabas field is defined in the descendant PE/MU segment.

Switching from RL to FIND mode is also performed if a field is defined:

- With TYPE=SPR and the server is running in an OpenVMS environment.
- With TYPE=PDS (phonetic descriptor) or TYPE=HDS (hyperdescriptor).
- In a PE segment (is a part of periodic group).

The adapter uses Read Logical by ISN (L1) calls to retrieve all records for the entry segment when the:

- Report request does not contain an optimizable selection test on an inverted list or an ISN list.
- The Access File contains a SEQFIELD value for that segment and this value is equal to the ISN field name.

Adabas returns each record corresponding to an entry in the Address Converter. The records are in ascending value of the ISN.

The first IF statement in a request that refers to a field with INDEX=I determines the inverted list used for the Read Logical access for the root of the subtree.

When retrieving descendant segments, the Adapter for Adabas issues a Read Logical call using the descriptor pointed to by IXFLD. For more information on IXFLD, refer to *Implementing Embedded JOINs: KEYFLD and IXFLD* on page 190.

For CALLTYPE=RL, all other selection tests on descriptor fields specified in your report request are applied after the record is returned.

USE=FIND

The Adapter for Adabas cannot read sub/superdescriptors that are derived from PE/MU access types and defined in a root segment. These types of fields may be used only in an Adabas FIND command that produces a "trusted" answer set. However, you can add the description parameter USE=FIND in the Access File for sub and superdescriptor fields that cannot be read by the adapter.

The following processing rules apply for fields that are defined with this description or that are automatically recognized as a fields derived from PE/MU:

- The Adabas command S1 is issued even if CALLTYPE is RL in the Access File.
- If the field is used in a PRINT/WRITE list, the adapter issues the error message:

  ```
  (FOC4582) THIS NOP/SPR FIELD CAN BE USED IN FIND CALLS ONLY.
  ```

- If the field is used in a complex WHERE condition and cannot be fully converted to the generated FIND call, the adapter issues the error message:

  ```
  (FOC4493) THIS NOP/SPR FIELD CANNOT BE USED IN COMPLEX FIND
  ```

The Create Synonym facility always places sub/superdescriptors derived from PE/MU in a root segment with TYPE=NOP in the Access File. Moreover, the sub descriptors have the description USE=UFIND in the Access File.

SEQFIELD

The SEQFIELD attribute specifies the field you want to use as the sequencing value:

```
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = EMPLOYEES                          DICTIONARY =
SEGNAM=S01,ACCESS=ADBS,FILENO=001,DBNO=1,CALLTYPE=RL,
           SEQFIELD=PERSONNEL_ID,$
```

PASS

The PASS attribute specifies the Adabas password for the file. It is required if the file is password protected.

You must specify the password for each password-protected file you use. For example:

```
SEGNAM=ONE    ,FILENO=1    ,DBNO=1    ,PASS=ONEXX ,...,$
SEGNAM=PAY    ,FILENO=2    ,DBNO=3    ,PASS=USER2 ,...,$
```

FETCH

The FETCH attribute indicates whether to use the Fetch feature for segments described as ACCESS=ADBS in the Access File. Valid values are ON (default) or OFF.

FETCHSIZE

The FETCHSIZE attribute sets the number of records per buffer. You can supply a specific number or have the Adapter for Adabas automatically calculate the maximum number of records that fit in a 32K buffer.

The following is an example of an Access File that enables the Fetch feature and sets the number of records per buffer to 15.

```
$$$ FILENAME=EMPFILE1,SUFFIX=ADBSINX,$
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = EMPLOYEES                          DICTIONARY =
SEGNAM=S01,ACCESS=ADBS,FILENO=001,CALLTYPE=RL,
           SEQFIELD=PERSONNEL_ID,FETCH=ON,FETCHSIZE=15,$
```

Mapping Adabas Descriptors

Adabas descriptors, superdescriptors, and subdescriptors must be declared in Master and Access Files in certain ways:

- When creating Master Files for fields that are descriptors, use the INDEX=I attribute. The Access File must also contain information about the descriptors, specifying the TYPE as DSC, SPR, or NOP. Identifying descriptors in the Access File directs the server to inverted lists to speed retrieval of these fields.
- Adabas fields described as superdescriptors must be declared in the Master File using the GROUP attribute. In the Access File, the TYPE must be SPR.

Specifying INDEX=I

Descriptors act as key values associated with a single field in an Adabas record. They enable records to be retrieved more efficiently based on the selection of a value, a set of values, or a range of values.

Additionally, all descriptors, superdescriptors, and subdescriptors are used to establish logical relationships between files. There are two methods for establishing logical relationships:

- By establishing the relationship dynamically at run time with the JOIN command. For more information about using Adabas files that are to be cross-referenced using JOIN, see *Adapter Navigation* on page 227.
- By using a static cross-reference in the Master and Access Files. For information on how to define shared files, see *Implementing Embedded JOINs: KEYFLD and IXFLD* on page 190.

Adabas descriptor fields are identified in the Master File using the INDEX=I attribute. For example:

```
FIELD=MAKE ,ALIAS=AD ,USAGE=A20 ,ACTUAL=A20 ,INDEX=I ,$
```

INDEX=I is optional in the Master File, but using it is recommended so that keys in your Master File are easily recognized without reference to the Access File.

Describing Superdescriptors

A superdescriptor is a key value associated with all or part of two to twenty Adabas fields. If the superdescriptor consists of a group of complete fields, it is declared differently than a superdescriptor which consists of one or more partial fields. For information on superdescriptors consisting of partial fields, see *Customizing the Adabas Environment* on page 201.

Superdescriptors can be printed if they contain only alphabetic fields.

Specifying Superdescriptors Using the GROUP Attribute

A superdescriptor composed of several complete fields is described with the GROUP attribute. All the fields that are part of the group must be specified immediately after the GROUP attribute in the order in which they appear in the superdescriptor.

The following example shows a superdescriptor defined in server terminology:

```
GROUP=TRANS          ,ALIAS=S1 ,USAGE=A20   ,ACTUAL=A20 ,INDEX=I ,$
   FIELD=ACCT_NO     ,ALIAS=C2 ,USAGE=A9    ,ACTUAL=A9  ,$
   FIELD=ITEM_NO     ,ALIAS=GD ,USAGE=A5    ,ACTUAL=A5  ,$
   FIELD=TRANS_DATE ,ALIAS=D7 ,USAGE=A6YMD ,ACTUAL=A6  ,$
```

The group field name, in this case, is TRANS. Since it is a superdescriptor, the INDEX=I attribute is included on the GROUP specification.

The ALIAS is the two-character Adabas field name for the superdescriptor.

The USAGE and ACTUAL values must be specified in alphanumeric format. See *Calculating GROUP Length* on page 185 for more information.

If any of the components of the TRANS group field were descriptors, they could also contain the INDEX=I attribute.

Note: TYPE=SPR must be defined in the Access File. For more information, see *Customizing the Adabas Environment* on page 201.

Calculating GROUP Length

For a group field, you must supply both the USAGE and ACTUAL values in alphanumeric format.

If the component fields of the group are alphanumeric, the USAGE and ACTUAL lengths of the group field must be exactly the sum of the component field lengths. For example, in the *Specifying Superdescriptors Using the GROUP Attribute* on page 185, the lengths specified in the USAGE and ACTUAL attributes for the component fields ACCT_NO, ITEM_NO, and TRANS_DATE each total 20. The lengths specified in the USAGE and ACTUAL attributes of the TRANS group field are consequently both equal to 20.

If the component fields of the group are *not* alphanumeric:

- The USAGE and ACTUAL formats of the group field must still be alphanumeric.
- The ACTUAL length of the group field is still the sum of the component field lengths.
- The USAGE length is the sum of the internal storage lengths of the component fields.

You determine these internal storage lengths as follows:

USAGE	Length
A (alphanumeric)	Value equal to the number of characters contained in the field
D (decimal, double-precision)	8
F (decimal, single precision)	4
I (integer)	4
P (packed decimal):	
P*n* or P*n.d*, where *n* is less than or equal to 15	8
P16	16
P16.*d*	8
P*n* or P*n.d*, where *n* is greater than 16 or less than or equal to 31	16
Z (zoned)	Value equal to the number of characters contained in the field

For example, consider the following GROUP specification in the EMPLOYEES Master File:

```
GROUP=LEAVE_DATA    ,ALIAS=A3 ,A16 ,A4 ,$
  FIELD=LEAVE_DUE   ,ALIAS=AU ,P2  ,Z2 ,$
  FIELD=LEAVE_TAKEN ,ALIAS=AV ,P2  ,Z2 ,$
```

In this example:

- The lengths of the ACTUAL values for the component fields LEAVE_DUE and LEAVE_TAKEN total 4, which is the length of the ACTUAL value for the group field.

- The length of the USAGE value for the group field is determined by adding the internal storage lengths of the component fields LEAVE_DUE and LEAVE_TAKEN, as specified by the field types: a length of 8 for USAGE P2 (8 plus 8 = 16).

Here is a GROUP specification:

```
GROUP=MODEL_YEAR_MAKE ,ALIAS=AO ,A28 ,A22 ,INDEX=I ,$
  FIELD=YEAR          ,ALIAS=AG ,P2  ,Z2  ,$
  FIELD=MAKE          ,ALIAS=AD ,A20 ,A20 ,INDEX=I ,$
```

In this example:

- The lengths of the ACTUAL values for the component fields YEAR and MAKE total 22, which is the length for the ACTUAL value for the group field.
- The length of the USAGE value for the group field is determined by adding the internal storage lengths of the component fields YEAR and MAKE, as specified by the field types: a length of 8 for USAGE P2 and a length of 20 for USAGE A20 (8 plus 20 = 28).

Describing Descriptors in the Access File

Field suffixes are specified in the Access File to identify descriptors, superdescriptors, and subdescriptors.

The syntax is

```
FIELD[NAME]=fieldname, TYPE=fieldsuffix, [NU={YES|NO}] ,$
```

where:

fieldname

Is the field name or group in the Access File.

fieldsuffix

Indicates the field suffix. Possible values are:

DSC which indicates a descriptor.

SPR which indicates a superdescriptor made up of whole fields.

NOP which indicates a subdescriptor or superdescriptor made up of partial fields.

PDS which indicates a phonetic descriptor.

HDS which indicates a hyperdescriptor.

blank which indicates non-descriptor fields.

NU

Specifies whether null-suppression is in use. Possible values are:

YES which indicates that the field is described in the adapter with null-suppression.

Note: Descriptors with null values are not stored in inverted lists.

NO which indicates null-suppression is not used. NO is the default value.

Specifying Superdescriptors Containing Partial Fields

If a superdescriptor consists of one or more partial fields, that superdescriptor (field) is defined with TYPE=NOP (non-printable) in the Access File. This type of descriptor can be used in selection tests, but neither it nor any part of it can be printed or displayed unless the field is alphanumeric.

The partial fields that comprise such superdescriptors are stored in Adabas. There is no facility or necessity for identifying them to the server or the adapter. If you look at an Access File that contains a superdescriptor composed of partial fields, you would recognize it by TYPE=NOP, but you cannot list the partial fields that are its components. To use the adapter, identify such a superdescriptor in the Access File with TYPE=NOP.

Any superdescriptor defined to the server with TYPE=NOP has the following limitation: CALLTYPE=RL is not supported when this field is the IXFLD in an embedded cross-reference or JOIN.

See your Software AG documentation for more information about using superdescriptors containing partial fields.

Specifying Subdescriptors

A subdescriptor consists of a partial field value for which an index has been created in Adabas. It is described at the field level in the Access File as TYPE=NOP. It can be used in selection tests, but it cannot be printed.

Any subdescriptor defined in the Access File with TYPE=NOP has the following limitation: CALLTYPE=RL is not supported when this field is the IXFLD in an embedded cross-reference or JOIN.

Specifying Phonetic Descriptors

A phonetic descriptor consists of similar phonetic values for which an index has been created in Adabas. It is described at the field level in the Access File as TYPE=PDS. It can be used in selection tests, but it cannot be printed.

Specifying Hyperdescriptors

A hyperdescriptor consists of values generated, based on a user-supplied algorithm, for which an index has been created in Adabas. It is described at the field level in the Access File as TYPE=HDS. It can be used in selection tests, but it cannot be printed.

Any phonetic descriptor or hyperdescriptor defined in the Access File with TYPE=PDS/HDS has the following limitation: CALLTYPE=RL is not supported when this field is the IXFLD in an embedded cross-reference or JOIN.

If you have selected a field defined with TYPE=NOP (for example, subdescriptors), TYPE=PDS or TYPE=HDS, a FIND call is issued even if RL has been specified.

Specifying Null-Suppression

To allow the Adapter for Adabas to create the most efficient calls, while still maintaining integrity of the answer set, any null-suppressed fields that are components of a superdescriptor must be defined in the Access File. The NU attribute is used to define a null-suppressed field.

An NU field defined as a descriptor is not stored in inverted lists when it contains a null value. Any qualifying descriptor records containing a null value are not recognized by a FIND command that refers to that descriptor.

The same is true for subdescriptors and superdescriptors derived from fields described to the adapter with null-suppression. No entry is made for a subdescriptor if the bytes of the field from which it is derived contain a null value and that field is defined with null-suppression (NU). No entry is made for a superdescriptor if any of the fields from which it is derived is an NU field with a null value.

For more information about null-suppression and how it affects data retrieval, see your Software AG documentation.

Specifying Support for SQL-Compatible Null Representation

Two additional data definition options are provided to enable specification of SQL-compatible null representation and handling by the Adapter for Adabas. The NC (not counted) and NN (not null) options can be placed in Access File field definitions to control evaluation and handling of null values. (Note that the NN option is only permitted when the NC option is also specified.)

See *Server File Structure* on page 143 for an overview of these options, and *Creating Synonyms When Adabas Fields Are Defined With the NC Option* on page 152 for a detailed explanation and examples of both the Master Files and Access Files following issuance of Create Synonym.

Implementing Embedded JOINs: KEYFLD and IXFLD

The KEYFLD and IXFLD attributes identify the common fields for parent/descendant relationships in a multi-segment Master File. These relationships are referred to as embedded JOINs or server views.

For each descendant segment, the KEYFLD and IXFLD attributes specify the field names of the shared field that implements the embedded JOIN. The parent field supplies the value for cross-referencing; the descendant field contains the corresponding value. The adapter implements the relationship by matching values at run time.

The KEYFLD and IXFLD attributes are valid only for ACCESS=ADBS segments.

Attribute	Description
KEYFLD	Field name in the parent segment whose value is used to retrieve the child segment. This is also known as the primary key.
IXFLD	Field name in the child or cross-referenced segment containing the related data. This is also known as the foreign key.

The value for the KEYFLD attribute is a 1- to 66-character field name or alias from the parent segment. The value for the IXFLD attribute is a 1- to 66-character field name or alias from the descendant segment. This is an example of a Master File with an embedded JOIN using KEYFLD and IXFLD.

```
FILENAME=AMKTORDR     ,SUFFIX=ADBSINX ,$
SEGNAME=MKTORDER
FIELDNAME=NMARKET_GRP     ,BA          ,I3      ,I2,   INDEX=I,$
FIELDNAME=QPRODUCT        ,BB          ,I3      ,I2       ,$
FIELDNAME=QNEEDITM        ,BC          ,A3      ,I2       ,$
FIELDNAME=FBUILD          ,BD          ,A1      ,A1       ,$
FIELDNAME=FK_NPRODUCT     ,BE          ,A4      ,A4       ,$
FIELDNAME=FK_NCUSTOMER    ,BF          ,I3      ,I2       ,$
FIELDNAME=DATEMKTO        ,BG          ,A8      ,A8       ,$
FIELDNAME=DATEFBLD        ,BH          ,A8      ,A8       ,$

SEGNAME=CUSTOMER, SEGTYPE=U,PARENT=MKTORDER,$
FIELDNAME=NCUSTMR_GRP     ,AA          ,I3      ,I2,   INDEX=I,$
FIELDNAME=NAMECUST        ,AB          ,A15     ,A15      ,$
FIELDNAME=DCUSROAD        ,AC          ,A20     ,A20      ,$
FIELDNAME=DCUSTOWN        ,AD          ,A20     ,A20      ,$
```

This is an example of an Access File with an embedded JOIN using KEYFLD and IXFLD.

```
RELEASE=6,    OPEN=YES,$
  SEGNAM=MKTORDER,    ACCESS=ADBS,FILENO=022,DBNO=001 ,$
  SEGNAM=CUSTOMER,    ACCESS=ADBS,FILENO=021,DBNO=001 ,CALLTYPE=FIND,
IXFLD=NCUSTMR_GRP,KEYFLD=FK_NCUSTOMER,$
```

Note: Include the pair of attributes in the Access File segment declaration for descendant segments. Do not specify them in the segment declaration for the root segment.

A JOIN can be based on more than one field in the host and cross-referenced logical record types. If the Adabas file uses multiple fields to establish a relationship or link between logical record types, you can specify concatenated fields in an embedded JOIN. You can also specify multiple fields with the dynamic JOIN command.

In the multi-field embedded JOIN, the KEYFLD and IXFLD values consist of a list of their component fields separated by slashes (/). Additional Access File attributes are not required. The syntax is

```
KEYFLD=field1/field2/...,
IXFLD=cfield1/cfield2/...,$
```

where:

field1/field2...

Is a composite of up to 16 key fields from the parent segment. Slashes are required.

cfield1/cfield2...

Is a composite of up to 16 key fields from the descendant segment.

The adapter compares each field pair for the data formats prior to format conversion. It evaluates each field pair with the following rules:

- The cross-referenced field in the embedded JOIN must be an Adabas descriptor field. The host field can be any field.
- Parent and descendant fields must be real fields.
- All participating fields for either the parent or descendant file must reside in the same segment.
- KEYFLD and IXFLD attributes must specify the same number of fields. If the format of the parent field is longer than the format of the descendant field, its values are truncated. If the format of the parent field is shorter, its values are padded with zeros or blanks.
- The KEYFLD and IXFLD attributes can consist of a maximum of 16 concatenated fields in order of high-to-low significance. You must specify the field order: the order determines how the values will be matched.
- The pair of fields in the KEYFLD/IXFLD attribute does not have to have comparable data formats.

To implement JOINs, the Adabas DBMS converts the alphanumeric field formats on the server to equivalent Adabas field formats in order to perform the necessary search and match operations. When the Adabas DBMS returns the answer set of matched values, it also converts the values back to alphanumeric formats. The cross-referenced fields must be descriptor fields.

Mapping Adabas Files With Variable-Length Records and Repeating Fields

The OCCURS segment attribute is used by the server to describe MU and PE field types in a Master File.

Consider the sample Adabas file VEHICLES. The FDT for the VEHICLES file is shown below.

```
**********************************
* FILE     2 (VEHICLES        ) *
**********************************
FIELD DESCRIPTION TABLE
      I      I        I        I              I                    I
LEVEL I NAME I LENGTH I FORMAT I  OPTIONS     I  PARENT OF         I
      I      I        I        I              I                    I
------I------I--------I--------I--------------I--------------------I
      I      I        I        I              I                    I
  1   I  AA  I   15   I    A   I DE,UQ,NU     I                    I
  1   I  AB  I    4   I    F   I FI           I                    I
  1   I  AC  I    8   I    A   I DE           I                    I
  1   I  CD  I        I        I              I                    I
  2   I  AD  I   20   I    A   I DE,NU        I SUPERDE            I
  2   I  AE  I   20   I    A   I NU           I                    I
  2   I  AF  I   10   I    A   I DE,NU        I                    I
  1   I  AG  I    2   I    U   I NU           I SUPERDE            I
  1   I  AH  I    1   I    A   I DE,FI        I                    I
  1   I  AI  I    1   I    A   I FI           I                    I
  1   I  AJ  I    6   I    U   I NU           I SUPERDE            I
  1   I  AK  I        I        I              I                    I
  2   I  AL  I    3   I    A   I NU           I                    I

```

The MU field, MAINT_COST, is a field in VEHICLES. It is allocated to a new segment, AM0101, required by the adapter, as shown in the Master File for a partial view of the VEHICLES file, illustrating the use of OCCURS=*occursname*:

```
$$$ CREATED ON 12/10/97 AT 10.17.27 BY PMSMJB
FILENAME=ADACAR,SUFFIX=ADBSINX,$

$ ADABAS FILE = VEHICLES-FILE                    DICTIONARY = 6
SEGNAME=S01     ,SEGTYPE=S,$

 FIELD=REG_NUM                  ,ALIAS=AA      ,A15 ,A15  ,INDEX=I,$
 FIELD=CHASSIS_NUM              ,ALIAS=AB      ,I9  ,I4   ,$
 FIELD=PERSONNEL_ID             ,ALIAS=AC      ,A8  ,A8   ,INDEX=I,$
 FIELD=CLASS                    ,ALIAS=AH      ,A1  ,A1   ,INDEX=I,$
 FIELD=LEASE_PUR                ,ALIAS=AI      ,A1  ,A1   ,$
 FIELD=DATE_ACQ                 ,ALIAS=AJ      ,P6  ,Z6   ,$
$GRMU=CAR_MAINTENANCE           ,ALIAS=AK      ,A11 ,A7   ,$
  FIELD=CURR_CODE               ,ALIAS=AL      ,A3  ,A3   ,$
  FIELD=MAINT_COST_CNT          ,ALIAS=AMC     ,I4  ,I2   ,$
 FIELD=DAT_ACQ_DESC             ,ALIAS=AN      ,A4  ,A4   ,INDEX=I,$
 GROUP=MODEL_YEAR_MAKE          ,ALIAS=AO      ,A28 ,A22  ,INDEX=I,$
  FIELD=YEAR_S02                ,ALIAS=AG      ,P2  ,Z2   ,$
  FIELD=MAKE_S02                ,ALIAS=AD      ,A20 ,A20  ,INDEX=I,$

SEGNAME=AM0101 ,SEGTYPE=S,PARENT=S01  ,OCCURS=AMC,$  MAX= 60
 FIELD=MAINT_COST               ,ALIAS=AM      ,P7  ,P4   ,$
 FIELD=AM0101_OCC               ,ALIAS=ORDER   ,I4  ,I2   ,$
```

In the original segment, the MAINT_COST_CNT (ALIAS=AMC) field contains the total number of occurrences of the MAINT_COST field. The new segment, AM0101, contains the MAINT_COST data field and the newly created AM0101_OCC field. The AM0101_OCC field contains the position of each occurrence.

This example includes the group field called CAR_MAINTENANCE, which contains the MU field, MAINT_COST. You cannot report on a group with an unknown length. However, the component fields can be referenced for reporting purposes.

Note: The Create Synonym facility creates the new segment, AM0101, for you. Otherwise, you must create the new segment using the OCCURS segment attribute.

The following is the Access File for the VEHICLES file:

```
$$$ CREATED ON 12/10/03 AT 10.17.27 BY PMSMJB
$$$ FILENAME=ADACAR,SUFFIX=ADBSINX,$
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = VEHICLES-FILE                      DICTIONARY = 6
SEGNAM=S01   ,ACCESS=ADBS,FILENO=002,
              CALLTYPE=RL,SEQFIELD=PERSONNEL_ID,$
 FIELD=DAT_ACQ_DESC                          ,TYPE=NOP,$
 FIELD=MODEL_YEAR_MAKE                       ,TYPE=SPR,$
  FIELD=YEAR_S02                             ,TYPE=   ,NU=YES,$
  FIELD=MAKE_S02                             ,TYPE=DSC,NU=YES,$
SEGNAM=AM0101,ACCESS=MU  ,FILENO=002,$ MAINT_COST
```

A new segment is created for the MU field. Note that for this new segment, ACCESS=MU.

Here is an example of the counter fields. The AMC field contains the total count of occurrences, the AM field contains the actual data, and the ORDER field contains the position of each occurrence.

```
     (AMC)          (AM)        (ORDER)
MAINT_COST_CNT   MAINT_COST   AM0101_OCC
--------------   ----------   ----------
             1          520            1
-----------------------------------------
             1          210            1
-----------------------------------------
             4           44            1
             4          322            2
             4           66            3
             4          188            4
-----------------------------------------
             6          324            1
             6         1103            2
             6          566            3
             6          755            4
             6          988            5
             6         1899            6
-----------------------------------------
             2          344            1
             2          500            2
```

In some cases, the ORDER field may describe the months of the year (1 to 12). If all occurrences for the month of June are needed, for example, you would print data in which the ORDER field is equal to 6 (for June).

Using the preceding sample data, here is an example of how to use the ORDER field. This request always selects the sixth occurrence of maintenance costs:

```
TABLE FILE VEHICLES
PRINT MAINT_COST
WHERE AM0101_OCC EQ 6
END

MAINT_COST
----------
      1899
```

Using the same data, this request always selects the second occurrence of maintenance costs:

```
TABLE FILE VEHICLES
PRINT MAINT_COST
WHERE AM0101_OCC EQ 2
END

MAINT_COST
----------
       322
      1103
       500
```

Describing Multi-Value Fields and Periodic Groups With the OCCURS Attribute

The OCCURS attribute is a segment attribute used to describe portions of records containing a multi-value field or a periodic group. When describing Adabas files, the OCCURS attribute may be equal to the field name or (another option) to the two-character internal Adabas name appended with the letter C.

Records with repeating fields are defined in the Master File by describing the singly occurring fields in the parent segment, and the multiply occurring fields or groups in their own subordinate segment. The OCCURS attribute appears in the declaration for the subordinate segments.

The syntax is

```
OCCURS=occursname ,$
```

where:

occursname

Indicates a data field in the parent segment that contains the number of occurrences of the descendant segment. Its value is derived from the two-character internal Adabas name (ALIAS attribute in the Master File) appended with the letter C.

The following is an example of the VEHICLES Master File, containing an MU segment with the counter field in the parent segment:

```
FILENAME=VEHICLES,SUFFIX=ADBSINX,$
  SEGNAME=S01     ,SEGTYPE=S,$
   FIELD=REG_NUM          ,ALIAS=AA          ,A15    ,A15  , INDEX=I,$
   FIELD=CHASSIS_NUM      ,ALIAS=AB          ,I9     ,I4   ,$
   FIELD=PERSONNEL_ID     ,ALIAS=AC          ,A8     ,A8   , INDEX=I,$
   FIELD=CLASS            ,ALIAS=AH          ,A1     ,A1   , INDEX=I,$
   FIELD=LEASE_PUR        ,ALIAS=AI          ,A1     ,A1   ,$
   FIELD=CURR_CODE        ,ALIAS=AL          ,A3     ,A3   ,$
   FIELD=MAINT_COST_CNT   ,ALIAS=AMC         ,I4     ,I2   ,$
   GROUP=MODEL_YEAR_MAKE  ,ALIAS=AO          ,A28    ,A22  , INDEX=I,$
    FIELD=YEAR            ,ALIAS=AG          ,P2     ,Z2   ,$
    FIELD=MAKE            ,ALIAS=AD          ,A20    ,A20  , INDEX=I,$
SEGNAME=AM0101  ,SEGTYPE=S ,PARENT=S01  ,OCCURS=AMC,$
   FIELD=MAINT_COST       ,ALIAS=AM          ,P7     ,P4   ,$
   FIELD=AM0101_OCC       ,ALIAS=ORDER       ,I4     ,I2   ,$
```

MAINT_COST is the MU field. It is allocated to the newly created segment, AM0101. The counter field, MAINT_COST_CNT, is located in the parent segment. The new segment, AM0101, uses this counter field to determine the number of occurrences of the MAINT_COST field (OCCURS=AMC).

Notice that the fields MAINT_COST_CNT and AM0101_OCC (ALIAS=ORDER) have USAGE=I4 and ACTUAL=I2. These are the required values for the USAGE and ACTUAL attributes of the counter field and the ORDER field.

The adapter builds the PE segment in the same way. However, the component fields within the PE group are defined in the new segment.

The following is a view of the EMPLOYEES Master File, containing a PE group:

```
FILENAME=EMPFILE1,SUFFIX=ADBSINX,$

SEGNAME=S01     ,SEGTYPE=S,$
 FIELD=PERSONNEL_ID              ,ALIAS=AA       ,A8    ,A8  ,INDEX=I,$
  FIELD=FIRST_NAME               ,ALIAS=AC       ,A20   ,A20 ,$
  FIELD=NAME                     ,ALIAS=AE       ,A20   ,A20 ,INDEX=I,$
FIELD= LEAVE_BOOKED_CNT          ,ALIAS=AWC      ,I4    ,I2  ,$
SEGNAME=AW0401   ,SEGTYPE=S,PARENT=S01   ,OCCURS=AWC,$
 GROUP=LEAVE_BOOKED              ,ALIAS=AW       ,A16   ,A12 ,$
  FIELD=LEAVE_START              ,ALIAS=AX       ,P6    ,Z6  ,$
  FIELD=LEAVE_END                ,ALIAS=AY       ,P6    ,Z6  ,$
 FIELD=AW0401_OCC                ,ALIAS=ORDER    ,I4    ,I2  ,$
```

LEAVE_BOOKED is the PE group. It is allocated to the newly created segment, AW0401. The counter field, LEAVE_BOOKED_CNT, is located in the parent segment. The new segment, AW0401, uses this counter field to determine the number of occurrences of the LEAVE_BOOKED group (OCCURS=AWC).

The counter field, LEAVE_BOOKED_CNT, and the ORDER field, AW0401_OCC, require values of I4 for the USAGE attribute and I2 for the ACTUAL attribute.

The number of occurrences is limited by the original definition of the file to Adabas.

To retrieve the appropriate occurrence of a repeating field in a report request, specify the ORDER field in your Master File. See *Specifying OCCURS Segment Sequence: The ORDER Field* on page 198 for details.

For detailed information about defining MU fields and PE groups in the Access File, see *Segment Attributes in Access Files* on page 177.

Describing Multi-Value Fields Within Periodic Groups

This topic describes how to specify multi-value fields within periodic groups in the Master File. Define each multi-value field contained in the periodic group segment as a separate descendant segment of the periodic group.

A periodic group containing a multi-value field is defined as two separate segments.

All fields must be defined in the order in which they appear in the FDT.

Consider the EMPLOYEES file. It has a periodic group called INCOME, which contains one multi-value field, BONUS. Each counter field (for example, AQC) must be in its appropriate parent segment. The INCOME_CNT field is in the parent segment for the periodic group, INCOME. The BONUS_CNT field is in the parent segment for the MU field, BONUS. Any repeating fields within the periodic group are defined in the AQ0201 segment. Their corresponding Adabas two-character field names are the values for ALIAS with the appropriate values for USAGE and ACTUAL.

Here is the view of the Master File for this structure:

```
 FILENAME=EMPFILE1,SUFFIX=ADBSINX,$

   SEGNAME=S01     ,SEGTYPE=S,$
    FIELD=PERSONNEL_ID      ,ALIAS=AA        ,A8    ,A8  ,INDEX=I,$
     FIELD=FIRST_NAME       ,ALIAS=AC        ,A20   ,A20 ,$
     FIELD=NAME             ,ALIAS=AE        ,A20   ,A20 ,INDEX=I,$
1. FIELD=INCOME_CNT        ,ALIAS=AQC       ,I4    ,I2  ,$

1. SEGNAME=AQ0201  ,SEGTYPE=S,PARENT=S01   ,OCCURS=AQC,$
1. $PEMU=INCOME            ,ALIAS=AQ        ,A19   ,A13 ,$
1.    FIELD=CURR_CODE       ,ALIAS=AR        ,A3    ,A3  ,$
1.    FIELD=SALARY          ,ALIAS=AS        ,P9    ,P5  ,$
2.   FIELD=BONUS_CNT        ,ALIAS=ATC       ,I4    ,I2  ,$
1. FIELD=AQ0201_OCC        ,ALIAS=ORDER     ,I4    ,I2  ,$

2. SEGNAME=AT0301  ,SEGTYPE=S,PARENT=AQ0201,OCCURS=ATC,$
2.  FIELD=BONUS            ,ALIAS=AT        ,P9    ,P5  ,$
2.  FIELD=AT0301_OCC       ,ALIAS=ORDER     ,I4    ,I2  ,$
```

1. PE fields.

This example includes the periodic group called INCOME, which contains the MU field, BONUS. Create Synonym comments out the group field with $PEMU because its length is variable (depending on the number of occurrences of the MU field). The server cannot report on a group with an unknown length. However, the component fields can be referenced for reporting purposes.

2. MU fields.

   BONUS_CNT (ALIAS=ATC) is the counter field. It is defined in the PE segment and tells us the number of occurrences for that field. Used in the MU segment, it indicates how many times this repeating field occurs, for example, OCCURS=ATC. Defined in the parent segment, the counter field is used by the child segment to tell us how many occurrences to expect.

   Any periodic group segment must be described in its entirety. This description has two requirements: each field of the periodic group must have a field declaration in the periodic group segment, and each field in the group must be described in the order in which it appears in the Adabas FDT.

Specifying OCCURS Segment Sequence: The ORDER Field

There may be occasions with OCCURS segment processing when the order of the data is significant. For example, the field values may represent monthly or quarterly data, but the record itself may not explicitly specify the month (or quarter) to which the data applies. The ORDER field maintains the sequence number for each multiply occurring instance.

The order of the occurrences of a multi-value field or periodic group also has some significance in your application. For example, if a periodic group contains 12 occurrences, each occurrence could correspond to one month of the year. The first occurrence represents January, the second February, and so on through to December.

To use the ORDER option, you must include an additional field in your Master File with an ALIAS of ORDER. This option instructs the server to determine the sequence number of fields in an OCCURS segment. The server automatically supplies a value for the new field that defines the sequence number of each repeating group. The ORDER field does not represent an existing Adabas field; it is used only for internal processing.

The syntax rules for the ORDER field are:

- It must be the last field described in the OCCURS segment.
- The field name must be unique.
- The ALIAS value must be ORDER.

- The USAGE value must be I4, with any appropriate display options.
- The ACTUAL value must be I2 (in earlier releases, I1 was used).

Each field with the ALIAS value ORDER tracks the order of occurrence of the preceding fields in the segment. Therefore, in the sample Master File in *Describing Multi-Value Fields Within Periodic Groups* on page 197, AT0301_OCC maintains the sequence of BONUS occurrences.

An ORDER field may be decoded into a meaningful value in a DEFINE.

Using the GROUP Attribute to Cross-Reference Files

The GROUP attribute can be used to cross-reference Adabas files if the file you want to search does not contain a descriptor. This cross-referencing can be done *only* if fields within the file you want to search correspond to descriptors in the file you are cross-referencing.

Consider this situation: You have a SALES file which contains salesman information. It also has account information, such as COMPANY_CODE, ITEM_NUMBER, and ITEM_NAME.

Suppose you also have an ACCOUNT file containing information about each company in the territory of a salesman. The ACCOUNT file has a superdescriptor consisting of COMP_CODE, IT_NUMBER, and IT_NAME. These fields correspond to the fields specified in the SALES file.

You can create a link between the matching fields in the SALES and ACCOUNT files. To do this, describe the matching fields from the SALES file as a group. Then you can join the group field to the superdescriptor in the ACCOUNTS file. The host file is the file, without a descriptor, containing the held values which must be grouped in order to retrieve related records in the second file. For example:

```
FILE=SALES     ,SUFFIX=ADBSINX     ,$
  SEGNAME=ACCT_SEG  ,SEGTYPE=S    ,$
    GROUP=LINKFLDS          ,ALIAS=    ,USAGE=A20 ,ACTUAL=A20 ,$
      FIELD=COMPANY_CODE    ,ALIAS=BA ,USAGE=A3  ,ACTUAL=A3  ,$
      FIELD=ITEM_NUMBER     ,ALIAS=BB ,USAGE=A5  ,ACTUAL=A5  ,$
      FIELD-ITEM_NAME       ,ALIAS=BC ,USAGE=A12 ,ACTUAL=A12 ,$
```

SALES is the host file which uses the superdescriptor (COMPANY) in the ACCOUNT file for the company-related data. The superdescriptor in the ACCOUNT file, easily recognized by TYPE=SPR in the Access File, is composed of fields that correspond to the dummy group in the host. Looking at the GROUP attribute used to cross-reference files, above, and the GROUP attribute used to cross-reference files, below, you see how the fields in the LINKFLDS group in the SALES file relate to the superdescriptor COMPANY in the ACCOUNT file:

```
FILE=ACCOUNT    ,SUFFIX=ADBSINX ,$
  SEGNAME=PROD_SEG  ,SEGTYPE=S  ,PARENT=ACCTS ,$
    GROUP=COMPANY     ,ALIAS=S1 ,USAGE=A20 ,ACTUAL=A20, INDEX=I,$
      FIELD=COMP_CODE ,ALIAS=AA ,USAGE=A3  ,ACTUAL=A3  ,$
      FIELD=IT_NUMBER ,ALIAS=AB ,USAGE=A5  ,ACTUAL=A5  ,$
      FIELD-IT_NAME   ,ALIAS=AC ,USAGE=A12 ,ACTUAL=A12 ,$
```

Use the GROUP superdescriptor COMPANY to retrieve data for those values using the JOIN command within a procedure. The JOIN command or embedded cross-reference completes the link. In this example, you would join LINKFLDS in SALES to COMPANY in ACCOUNT using the following syntax:

```
JOIN LINKFLDS IN SALES TO ALL COMPANY IN ACCOUNT AS J1
```

Platform-Specific Functionality

The Adapter for Adabas on UNIX and Windows, and OpenVMS, has more restrictions than on z/OS. These restrictions are described below.

On all platforms, if an error occurs while Adabas commands are being processed, then the communication block (CB) is returned along with the Response Code (RC) Additions 2 field, in 2 or 4 bytes binary format. The Additions 2 field indicates the specific reason for the Response Code. The Adapter for Adabas displays both RC and Additions 2 fields in the message. This information is available in the trace as well.

Reference: Functionality on z/OS

The following conditions apply when using the adapter on z/OS platforms:

- Sub/super descriptors defined with "NC=YES" and "MISSING=ON" parameters cannot be used to search for SQL NULL values, as that causes an Adabas RC 61.
- If you assign Server or Application Administrator privileges to user IDs other than the one used to install the server, to allow these additional administrators to create metadata for Adabas data sources, you must do one of the following:
  - Include the Adabas load library in your SYS1.PARMLIB(LNKLST*nn*) member.
  - Use the STEPLIBLIST feature and add the Adabas load library to the sanctioned list file. For full details on the STEPLIBLIST feature, see the IBM publication *UNIX System Services Planning Guide*.

    Tip: To locate the information in that document, search for STEPLIBLIST.

Reference: Functionality on UNIX and Windows

The following conditions apply when using the adapter on UNIX and Windows platforms:

- You cannot use non-descriptor fields as search criteria.
- The parameter NDFIND is automatically set to the OFF value if the adapter is executed in a non-mainframe environment. If non-descriptor fields are used as key fields, the entire database is read.
- If the Master File non-descriptor field is declared as an indexed field (INDEX=I or FIELDTYPE=I) and used as a key field, the result from Adabas is RC 61.
- If an occurrence of an MU (multi-value) field is deleted, the adapter shifts all other occurrences into its place and assigns an empty value for the last occurrence. If this field has an NU (null suppression) option, the last occurrence will be automatically deleted by Adabas.
- DBNO must be assigned to a valid numeric value for the existing database.

Reference: Functionality for OpenVMS Platform

Adabas on OpenVMS does not allow a direct request for sub/superdescriptors values. For this reason, there are some limitations on using these fields (with TYPE=NOP/SPR in ACX) in server requests to Adabas:

- NOP fields cannot be printed or displayed, even if they are alphanumeric.
- NOP/SPR fields cannot be used in functions (MIN, MAX, and so on).
- If NOP/SPR fields are used in the IF/WHERE criteria, then CALLTYPE=RL is automatically changed to CALLTYPE=FIND. It can change the sequence of returning data rows on OpenVMS in comparison with sequence on other platforms.
- NOP fields cannot be used in a complex IF/WHERE clause.
- NOP fields cannot be used for joining.

Customizing the Adabas Environment

The Adapter for Adabas provides several parameters for customizing the environment and optimizing performance.

The sections *Multifetch and Prefetch* on page 205, and *Adabas Dynamic Database Number* on page 207 describe the environment commands that display and change the parameters governing your server session.

ORDER Fields in the Indexed Field List

ORDER fields maintain the sequence number for each multiply occurring instance. ON is the default value and includes ORDER fields in the list of indexed fields.

Setting ORDERKEYS to OFF forces the Adapter for Adabas to exclude ORDER fields from the list of indexed fields.

Syntax: How to Set ORDERKEYS in the Indexed Field List

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET ORDERKEYS {ON|OFF}
```

where:

`ON`

Includes ORDER fields in the list of indexed fields. ON is the default value.

`OFF`

Excludes ORDER fields from the list of indexed fields.

Switching the Access Mode Using NOPACCESS

This setting allows you to switch the access mode from RL to FIND if a field defined with TYPE=NOP was selected (even if CALLTYPE=RL has been specified).

The default value for this setting is MIXED, which uses the default access mode for the selected field. The new setting can be useful when the NOP superdescriptor defined in a root segment is derived from fields that belong to different Master File segments.

Syntax: How to Set NOPACCESS

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET NOPACCESS {FIND|MIXED}
```

where:

FIND

Switches the access mode from RL to FIND if a field defined with TYPE=NOP was selected (even if CALLTYPE=RL has been specified).

MIXED

Uses the default access mode for the selected field.

NEW Synonym Setting for Superdescriptors

Setting SYNONYM to NEW instructs the Adapter for Adabas to use new logic when:

- Describing metadata.
- Processing requests that can take advantage of superdescriptors for screening conditions.

Note: This command must be specified in the server profile.

Syntax: How to Set Synonyms for Superdescriptors

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET SYNONYM {NEW|STD}
```

where:

NEW

Describes superdescriptors as groups in the Master File. With NEW synonym format, neither the groups nor their components (fields) have field names specified in the Master File. Aliases are populated using the Adabas FDT (2-byte name).

When a synonym contains the NEW syntax, the Adapter for Adabas uses NEW logic to process the selection criteria of requests involving that synonym. Screening conditions within the request are analyzed and the superdescriptor that covers the highest order component fields required by the selection criteria are used.

Note that you must specify CALLTYPE=RL in the Access File in order to take advantage of superdescriptor-based access.

STD

Incorporates the usual synonym creation behavior, which does not trigger the new logic for requests using superdescriptors. STD is the default value.

For more information on synonyms, see *Creating Synonyms* on page 147.

Example: Setting Synonyms for Superdescriptors

The following Master File illustrates superdescriptors Y6 and Y7 defined as GROUP, with the NEW synonym format:

```
GROUP=      ,ALIAS=Y6          ,A2    ,A2    ,INDEX=I,$
   FIELD=   ,ALIAS=AF          ,A1    ,A1    ,       ,$
   FIELD=   ,ALIAS=AG          ,A1    ,A1    ,       ,$
GROUP=      ,ALIAS=Y7          ,A22   ,A22   ,INDEX=I,$
   FIELD=   ,ALIAS=AF          ,A1    ,A1    ,       ,$
   FIELD=   ,ALIAS=AG          ,A1    ,A1    ,       ,$
   FIELD=   ,ALIAS=AC          ,A20   ,A20   ,       ,$
```

The corresponding Access File specifies the superdescriptors Y6 and Y7 and their components, using the keywords SUPER and NUMFLDS:

```
SUPER=Y6                ,NUMFLDS=2          ,$
  FIELD=AF_FIELD        ,TYPE=   ,NU=NO     ,$
  FIELD=AG_FIELD        ,TYPE=   ,NU=NO     ,$
 SUPER=Y7                ,NUMFLDS=3          ,$
  FIELD=AF_FIELD        ,TYPE=   ,NU=NO     ,$
  FIELD=AG_FIELD        ,TYPE=   ,NU=NO     ,$
  FIELD=AC_FIELD        ,TYPE=   ,NU=NO     ,$
```

SUPER specifies the native Adabas two-byte field name of the superdescriptor.

NUMFLDS defines the number of participating fields. Descriptions of all participating fields immediately follow the SUPER statement.

The request that follows uses superdescriptor Y6 in the L3 (Read Logical) command in the Access File:

```
TABLE FILE EMP211
PRINT AF_FIELD AG_FIELD AC_FIELD AD_FIELD
IF AF_FIELD EQ 'S'
IF AG_FIELD EQ 'M'
END
```

The next request uses superdescriptor Y7 in the L3 (Read Logical) command. Notice that it references an extra field in the last line of the Access File:

```
TABLE FILE EMP211
PRINT AF_FIELD AG_FIELD AC_FIELD AD_FIELD
IF AF_FIELD EQ 'S'
IF AG_FIELD EQ 'M'
IF AC_FIELD EQ 'C'
END
```

Multifetch and Prefetch

The Adabas Multifetch and Prefetch options reduce execution time and allow Adabas data to be retrieved with a high degree of efficiency. By buffering multiple record results from a single call, Multifetch and Prefetch reduce the communication overhead between the Adapter for Adabas and the Adabas nucleus.

The adapter uses the Multifetch option if it is available (this is the default option), or the Prefetch option if it is available. The option available is determined by your environment.

The adapter trace file contains the following information about the Fetch option:

- Fetch is allowed or disallowed.
- Fetch technique being used (Multifetch or Prefetch).
- Number of records per Fetch buffer.
- Size of the Fetch buffer (ISN buffer).

The Multifetch and Prefetch options require that OPEN=YES (the default value) is specified in the Access File. When OPEN=YES is specified, the Multifetch and Prefetch options are activated. There are two ways to deactivate (or reactivate) these options:

- Issue SET commands before running the request.
- Include the FETCH and FETCHSIZE attributes in the Access File.

Note: The SET commands override the Access File settings. This setting will be in effect for the entire server session.

Syntax: How to Set FETCH and FETCHSIZE

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET FETCH {ON|OFF|DEFAULT}
ENGINE ADBSINX SET FETCHSIZE {n|MAX[IMUM]}
```

where:

`ADBSINX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Sets the Fetch feature on for the user session.

OFF

Sets the Fetch feature off for the user session.

DEFAULT

Uses the information from the Access File. DEFAULT is the default value.

n

Is the number of records per buffer (1–32K). The buffer size varies with the size of the record and can be different for each TABLE request. The buffer size limit is 32K. 10 is the default value.

MAX[IMUM]

Is automatically calculated by the Adapter for Adabas to allow the maximum number of records that fit in a 32K buffer.

Syntax: How to Declare the FETCH and FETCHSIZE Attributes in the Access File

FETCH and FETCHSIZE are applicable only to segments described as ACCESS=ADBS in the Access File.

The Access File can contain the following attributes in the SEGNAM statement

```
FETCH={ON|OFF}
FETCHSIZE={n|MAX[IMUM]}
```

where:

ON

Sets the Fetch feature on for the user session. ON is the default value.

OFF

Sets the Fetch feature off for the user session.

n

Is the number of records per buffer (1 to 32k). 10 is the default value.

MAX[IMUM]

Is automatically calculated by the Adapter for Adabas to allow the maximum number of records that fit in a 32K buffer.

Here is an example of the FETCH and FETCHSIZE attributes in the sample Access File for EMPLOYEES:

```
$$$ FILENAME=EMPFILE1,SUFFIX=ADBSINX,$
RELEASE=6,OPEN=YES,$

$ ADABAS FILE = EMPLOYEES                          DICTIONARY =
SEGNAM=S01 ,ACCESS=ADBS,FILENO=001,CALLTYPE=RL,
             SEQFIELD=PERSONNEL_ID,FETCH=ON,FETCHSIZE=15,$
FIELD=DEPT_PERSON         ,TYPE=SPR,$
FIELD=DEPT_S03            ,TYPE=DSC,NU=YES,$
FIELD=NAME_S03            ,TYPE=    ,NU=NO,$
```

See your Software AG documentation for more information about the Multifetch/Prefetch feature.

Controlling Adabas Multifetch for Join Operations

You can use the FETCHJOIN command to take advantage of Multifetch efficiencies in Join operations for a session. This feature is particularly useful when you are joining to a base file in which sorting is based on the key field that is used for the join.

Syntax: How to Set Adabas FETCHJOIN

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET FETCHJOIN {ON|OFF}
```

where:

`ADBSINX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Sets the FETCHJOIN feature on for the user session. ON is the default value.

`OFF`

Sets the FETCHJOIN feature off for the user session. This value is recommended when joining with a base file that is unsorted by the key field used for joining. This option avoids buffering and reduces processing time.

Adabas Dynamic Database Number

Previous versions of the Adapter for Adabas required specification of the Adabas database number in the Access File using the DBNO attribute. This feature required a duplicate copy of the Access File for each database accessed.

Adabas database numbers can now be set from the server's profile. This SET command allows users to override the DBNO in the Access File. Note that specifying database numbers in the Access File is still supported. Use of the dynamic database number makes Master and Access Files shareable among databases.

The SET command remains valid throughout the server session.

Syntax: How to Set the Adabas Dynamic Database Number

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ADBSINX SET DBNO dbno
ENGINE ADBSINX SET DBNO dbno AFD afd
ENGINE ADBSINX SET DBNO dbno AFD afd SEG[NAM] segname
ENGINE ADBSINX SET ?
ENGINE ADBSINX SET DBNO DEFAULT
```

where:

`ADBSINX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`dbno`

Is any valid numeric database value between 0 and 255.

`afd`

Is any valid Access File name.

`segname`

Is any valid ADBS segname in the Access File.

`?`

Queries the current settings.

`DEFAULT`

Returns to the default settings for all previous settings. The DBNO is read from the Access File. If the attributes are not specified in the Access File, the adapter will determine the DBNO from the DDCARD.

Examples for z/OS are shown below:

`ENGINE ADBSINX SET DBNO 5`	Retrieves all data from database number 5.
`ENGINE ADBSINX SET DBNO 2 AFD EMPFILE`	Retrieves data for the EMPFILE from database number 2.

Note: Several commands can be issued for different files. Each command must be issued separately. Changes are cumulative. For example:

```
ENGINE ADBSINX SET DBNO 1 AFD EMPFILE
ENGINE ADBSINX SET DBNO 2 AFD EMP2
ENGINE ADBSINX SET DBNO 3 AFD VEHICLES
```

`ENGINE ADBSINX SET DBNO 2 AFD EMPFILE SEG S02`	Retrieves data for the EMPFILE in database number 2 for a particular ADBS segment (segment S02).
`ENGINE ADBSINX SET ?`	Displays your settings.
`ENGINE ADBSINX SET DBNO DEFAULT`	Returns to the default settings. This resets all SET DBNO commands for all Access Files.

Controlling Data Retrieval Types

The SET CALLTYPE command enables you to set the data retrieval type per session, file, or segment by switching dynamically between physical and logical reads.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

Example: Using Dynamic CALLTYPE

The following examples illustrate the use of variations of dynamic CALLTYPE syntax:

```
ENGINE ADBSINX SET CALLTYPE FIND
```

Uses FIND as the type of data retrieval call for all files.

```
ENGINE ADBSINX SET CALLTYPE RL AFD EMPFILE
```

Retrieves data for the EMPFILE using RL as the type of data retrieval call.

Note that you can issue several commands for different files. Each command must be issued separately. Changes are cumulative. For example, the following commands retrieve data for the EMPFILE using FIND as the type of data retrieval call for a particular ADBS segment (segment S02):

```
ENGINE ADBSINX SET CALLTYPE RL AFD EMPFILE

ENGINE ADBSINX SET CALLTYPE FIND AFD EMP2

ENGINE ADBSINX SET CALLTYPE MIXED AFD VEHICLES

ENGINE ADBSINX SET CALLTYPE FIND AFD EMPFILE SEGNAME S02
```

```
ENGINE ADBSINX SET ?
```

Displays your settings.

```
ENGINE ADBSINX SET CALLTYPE DEFAULT
```

Returns to the default settings. This command resets all SET CALLTYPE commands for all Access Files.

LA Fields

The SET LAFORMAT command affects Metadata for fields with LA options:

```
ENGINE ADBSINX SET LAFORMAT {DEFAULT|TX|Annnnn}
```

where:

`DEFAULT`

Maps the ADABAS LA field as fixed-length A500, A500.

`TX`

Maps the ADABAS LA field as text TX50, TX.

A*nnnnn*

(253 < *nnnnn* < 16382) maps LA field with a specified given range length.

UNICODE Fields in W-format

The command sets specified code-page on the field level when mapping ADABAS Unicode W-fields.

```
ENGINE ADBSINX SET WCODEPAGE {DEFAULT|OFF|nnnnn}
```

where:

DEFAULT

Corresponds to codepage 65003.

OFF

Means to process W as A (without conversion).

nnnnn

Means any valid codepage.

Adabas Reporting Considerations

Designers have great flexibility in coding the description of the part of the Adabas structure that they want to access. These topics describe the methods of file traversal that the Adapter for Adabas uses to determine the relative advantages of different file descriptions.

Adabas File Navigation Techniques

When you define specific hierarchical representations of Adabas structures in Master Files, you specify the order in which you want the Adapter for Adabas to retrieve records. This procedure is called navigational logic and is usually part of the application program. Navigation techniques using the JOIN command also work this way.

Referencing Subtrees and Record Retrieval

The Adapter for Adabas selects where to enter the subtree, called the point-of-entry, and the subsequent navigational processing, by analyzing the tree structure defined by your Master File (or JOIN structure) and report request. The adapter determines the smallest subtree that contains all the fields needed for retrieval to produce a report.

The smallest subtree is composed of those segments that contain fields referenced by the request, plus the minimum number of additional segments required to connect all the files used in the request.

The adapter retrieves records only in segments in the referenced subtree. Within the subtree, it retrieves records that contain fields required for the report request or records that are needed to provide the correct links between report fields.

The adapter always enters a database through the root segment of the referenced subtree.

Segment Retrieval Methodology

The Adapter for Adabas retrieves segments from top-to-bottom, then left-to-right at each level of the hierarchy. It retrieves all unique descendant segments before any non-unique descendant segments.

This treatment of unique segments is consistent with a basic server principle: for reporting purposes (though not for updating or file organization), a unique child is logically a direct extension of its parent. This principle is an important factor in selecting a structure that properly reflects your Adabas file. The results of SUM and COUNT operations on fields in child segments may depend on whether they have been declared unique or non-unique. The server also treats missing segments differently, depending on whether the segment is declared unique or non-unique.

Missing Unique Segments

If a segment is specified as unique (SEGTYPE=U or KU), the server regards it as a logical extension of the parent segment. The Adapter for Adabas automatically inserts default values (blanks for alphanumeric fields and zeros for numeric fields) if the unique child segment does not exist. As a result, unique segments are always present.

Syntax: How to Use Missing Non-Unique Segments

If a segment is specified as non-unique (SEGTYPE=S or KM), select one of three options for processing a record without descendant segments

```
SET ALL=all_option
```

where:

all_option
Allows for the processing of records with no descendant segments. Possible values are:

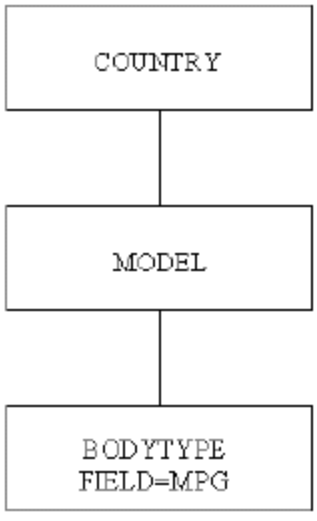
OFF which omits parent instances that are missing descendant segments from the report. OFF is the default value.

ON which includes parent instances that are missing descendant segments in the report.

PASS which includes parent instances that are missing descendant segments, even when IF criteria exist to screen fields in the missing instances of the descendant segment.

You can specify SET ALL in a profile or procedure.

The examples in the following topics describing the SET ALL command are based on the following structure:



SET ALL=OFF

The default option (SET ALL=OFF) rejects a record if the request calls for retrieval of a descendant segment and there is no descendent segment present.

For example, assume you have a file in which the parent segment is COUNTRY, which has a descendant segment named MODEL, which in turn has a descendant segment named BODYTYPE. Using the SET ALL=OFF option, the statement

```
COUNT BODYTYPE BY COUNTRY
```

does not print in the report the details of any country that did not produce at least one bodytype of a model of a car.

SET ALL=ON

The Adapter for Adabas displays the parent record, even if it has no descendant segments. In this case, using the SET ALL=ON option when processing the statement

```
COUNT BODYTYPE BY COUNTRY
```

displays the names of all countries and gives a count of zero (0) bodytypes for those without descendant segments.

However, if the request has an explicit screening test on the descendant segment, the absence of any descendant segments results in test failure. For example, the request

```
COUNT BODYTYPE BY COUNTRY
IF MPG GT 22
```

excludes any country without any bodytype segments from the report.

SET ALL=PASS

The third option, SET ALL=PASS, allows parents without a descendant segment to pass an explicit screening test on that descendant segment. The request

```
COUNT BODYTYPE BY COUNTRY
```

lists all countries with or without bodytype segments. The request

```
COUNT BODYTYPE BY COUNTRY
IF MPG GT 22
```

includes records without any bodytype segments, and those with an MPG greater than or equal to 22.

The ALL Prefix

Selectively apply SET ALL=ON by adding the ALL prefix to any field from the desired segment.

Reference the field either as a sort field (for example, BY ALL.COUNTRY or ACROSS ALL.COUNTRY) or as a display field (WRITE ALL.COUNTRY). As a result, the SET ALL=ON strategy is applied to any missing, immediate, non-unique descendants of the segment containing the ALL-prefixed field. The SET ALL=OFF option is in effect for all other segments.

For example, in the request

```
COUNT MODEL AND BODYTYPE BY ALL.COUNTRY
```

the SET ALL=ON option applies to the country segment and its descendant segments. Therefore, if there is a country without models (and consequently without bodytypes), the report shows that country. Any test condition on either the model or the bodytype segment nullifies the effect of the ALL prefix.

The global SET ALL settings of ON and PASS take precedence over the selective ALL prefix. The selective ALL prefix is effective only when the global setting is OFF, either explicitly or by default.

Adabas Selection Considerations

The Adapter for Adabas analyzes all selection criteria that apply to a specific report request and uses the criteria to minimize its search for data. If a record fails any of the selection tests, the server does not attempt to retrieve any descendant records. Retrieval continues with the next record in the parent segment. If there is no other record in that parent segment and it is not the root of the Master File, The server moves back up to the next record in the previous segment.

The selection tests that you impose on a high-level segment are much more efficient at reducing I/O operations than criteria imposed on lower-level segments. If you know in advance which selection criteria are likely to be used most frequently, design the Master File to take advantage of the hierarchical structure in the Adapter for Adabas.

Selection Order in the Access File

When a report request contains multiple optimizable selection tests, the order of descriptors in the Access File determines the order in which the server applies the selection tests. The server issues a Read Logical (RL) call using the first descriptor listed in the Access File that participates in a selection test.

Therefore, for efficient processing you should describe the most restrictive descriptor at the beginning of its segment in the Access File. The order of descriptors in the Master File has no effect on selection processing.

Syntax: How to Use RECORDLIMIT and READLIMIT

For any request, you may limit the number of Adabas records retrieved from the database and the number of read operations performed. Use the RECORDLIMIT and READLIMIT parameters to impose these limitations by adding the following conditions to a report request

```
{WHERE|IF} RECORDLIMIT {EQ|IS} n {WHERE|IF} READLIMIT {EQ|IS} n
```

where:

n

Is the number of records or read operations at which you want to limit the search.

You add these conditions to any report request, or incorporate them into file security through the DBA facility.

Consider the following example

```
TABLE FILE VEHICLES
PRINT PERSONNEL_ID MAKE MODEL YEAR
WHERE RECORDLIMIT EQ 5
END
```

which produces this report:

```
PAGE      1

PERSONNEL_ID   MAKE            MODEL               YEAR
------------   ----            -----               ----
11500330       CITROEN         BX LEADER             85
11400313       ALFA ROMEO      SPRINT GRAND PRIX     84
30034217       AUSTIN          MINI                  80
30034228       TALBOT          SOLARA                83
30008427       AUSTIN          MINI                  80
```

Notice that only five records are reported as requested.

Syntax: How to Use Optimization of the FIND Call Using Non-Descriptor Fields

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

It is possible to use non-descriptor fields as search criteria and have the calls to Adabas use the search buffer rather than read through the entire database.

The Adapter for Adabas provides improved optimization by allowing the search buffer to be generated using non-descriptor fields. This optimization occurs whenever CALLTYPE=FIND is specified in the Access File and you include an IF or WHERE test referencing a non-descriptor field in your report request.

It may prove to be more efficient to alter your retrieval strategy and perform a Read Physical (L2) call when large amounts of data exist. A SET command is provided for changing the default Adabas call when selecting non-descriptor fields.

```
ENGINE ADBSINX SET NDFIND {ON|OFF}
```

where:

`ENGINE`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Causes the search buffer to be generated with any field (non-descriptor and/or descriptor field). ON is the default value.

`OFF`

Causes the search buffer to be generated with only descriptor fields. If the request does not use any descriptor field, the Read Physical call is generated.

This command applies only if CALLTYPE=FIND is specified in the Access File.

Using the JOIN Command to Process Multiple Files

You can JOIN Adabas databases defined to the server to other Adabas databases or to any other fully joinable database that the server can read. Each JOIN creates a parent-child relationship. The parent field is called the host or *from* field. The child field is called the cross-referenced or *to* field.

You can JOIN to Adabas databases if the cross-referenced field is one of the following:

- A descriptor field.
- A superdescriptor defined with TYPE=SPR or NOP in the Access File.
- A subdescriptor defined with TYPE=NOP in the Access File.

In every case, in the Access File, the cross-referenced segment must specify ACCESS=ADBS.

If CALLTYPE=RL is specified for the cross-referenced segment, the host field can be joined to the high-order portion of a descriptor, superdescriptor, or subdescriptor.

When an Adabas file is the host file, the host field is one of the following:

- A non-recurring field (ACCESS=ADBS).
- A field in a periodic group (ACCESS=PE).
- A multi-value field (ACCESS=MU).

The Adapter for Adabas also supports DEFINE-based JOINs. Up to 16 JOINs can be in effect at one time.

Example: Multi-field JOIN and Short-to-Long JOIN Capability

For a multi-field JOIN, the number of fields used in the JOIN must be the same for both the host and the cross-referenced files. The cross-referenced fields must describe the left-most portion of a superdescriptor defined to the server using the GROUP attribute. Consider the following example.

```
JOIN FLDA AND FLDB IN ADBS1 TO KEY1 AND KEY2 IN ADBS2 AS J1
```

For the short-to-long JOIN, the cross-referenced field must be a descriptor, subdescriptor, or superdescriptor, or a field that describes the left-most portion of a GROUP superdescriptor.

Adabas Optimization With Null-Suppression for CALLTYPE=RL

In the Adapter for Adabas, optimization refers to using an index to retrieve the answer set. To ensure data integrity and complete answer sets, the Adapter for Adabas will perform optimization when all:

- Non-referenced component fields of a superdescriptor are *not* null-suppressed (NU=NO in the Access File).
- Component fields of a superdescriptor that contain null-suppressed fields (NU=YES in the Access File) are used in the selection criteria.

If a field is null-suppressed in Adabas (NU=YES in the Access File), any superdescriptor that uses this field has no entry on the inverted list when this field is blank (alphanumeric) or zero (numeric).

Master File With a Three-Field Superdescriptor

```
GROUP=SUPERG  ,ALIAS=S1 ,USAGE=A9 ,ACTUAL=A9 ,INDEX=I ,$
   FIELD=FLD1 ,ALIAS=AA ,USAGE=A3 ,ACTUAL=A3 ,$
   FIELD=FLD2 ,ALIAS=AB ,USAGE=A3 ,ACTUAL=A3 ,$
   FIELD=FLD3 ,ALIAS=AC ,USAGE=A3 ,ACTUAL=A3 ,$
```

Access File With a Three-Field Superdescriptor

```
FIELD=SUPERG    ,TYPE=SPR,$
   FIELD=FLD1  ,TYPE=   ,NU=YES ,$
   FIELD=FLD2  ,TYPE=   ,NU=NO  ,$
   FIELD=FLD3  ,TYPE=   ,NU=YES ,$
```

In order to optimize a selection test against a superdescriptor with null-suppression, you must explicitly reference the null-suppressed field in the superdescriptor. If you do not reference the null-suppressed field and the field has no data, there is no record in the index and optimization would return no records. To ensure correct results, the server will not optimize the selection test if the null-suppressed field is not referenced.

For more information about null-suppression and how it affects data retrieval, see your Software AG documentation.

Adabas Optimization on Group Fields

If a report request contains IF or WHERE selection tests against one or more fields that describe the left-most portion of a GROUP descriptor, the Adapter for Adabas combines this request into a test that uses the superdescriptor for greater efficiency. If any of the component (or parent) fields of the superdescriptor are defined to Adabas with null-suppression, be sure to note this information in the Access File to ensure accuracy of reads.

For example, consider the following Master File extract:

```
GROUP=SUPERD ,ALIAS=SD ,USAGE=A8 ,ACTUAL=A8 ,INDEX=I ,$
   FIELD=PART1 ,ALIAS=P1 ,USAGE=A4 ,ACTUAL=A4 ,$
   FIELD=PART2 ,ALIAS=P2 ,USAGE=A4 ,ACTUAL=A4 ,$
```

If, in a report request, you include the following two tests,

```
WHERE PART1 EQ 'ABCD'
WHERE PART2 EQ 'EFGH'
```

these two tests are equivalent to the following syntax:

```
WHERE SUPERD EQ 'ABCD/EFGH'
```

This combination uses the superdescriptor's inverted list and optimizes the Adabas call. This optimization is performed only if all null-suppressed (NU=YES) superdescriptor components are explicitly referenced in IF or WHERE tests.

Test on Group Field With Numerics

If you are testing on a group that contains numeric fields, the test must contain the sign byte. The Adapter for Adabas passes only one value per numeric field, based on the preferred sign values in Adabas. A sign value of F is passed for positive numbers and a sign value of D is passed for negative numbers. This sign value reduces the number of calls sent to Adabas and also eliminates the need for Adabas to perform any logical sign translation.

For example:

```
GROUP=GROUP1  ,ALIAS=S1  ,USAGE=A9  ,ACTUAL=A14  ,INDEX=I  ,$
   FIELD=FLD1 ,ALIAS=AA  ,USAGE=A3  ,ACTUAL=A3   ,$
   FIELD=FLD2 ,ALIAS=AB  ,USAGE=P3  ,ACTUAL=P3   ,$
   FIELD=FLD3 ,ALIAS=AC  ,USAGE=A3  ,ACTUAL=A3   ,$
```

In a report request, you must include the sign for the P3 field:

Mainframe platforms:

```
WHERE GROUP1 EQ 'ABC/123F/XYZ'
```

Non-mainframe platforms:

```
WHERE GROUP1 EQ 'ABC/123/XYZ'
```

Adabas Writing Considerations

The Adapter for Adabas is designed to support SQL update commands for an Adabas data source without the use of remote procedures. These topics describe the methods and rules related to write capability.

Adabas Write Adapter

Before you can use any commands that write to an Adabas data source, you must make the following changes to the Master and Access Files:

In the Master File:

- All segments must have SEGTYPE = S0 (for the Read Adapter, SEGTYPE=S is sufficient).
- Fields with ACTUAL format Z (zoned) must have a numeric USAGE format (P or I). Format A is supported only for reading an Adabas data source.

  Note: For the best performance, you can change ACTUAL format Z to ACTUAL format P in the Master File. In this case, you must also change the ALIAS attribute to contain the length and type. If the ALIAS is ff, and the field length is lll, the ALIAS attribute should be coded as:

  ```
  ALIAS='ff,lll,P'
  ```

  For example, consider the following field declaration:

  ```
  FIELD=LEAVE_DUE  ,ALIAS=AU  ,USAGE=P2  ,ACTUAL=P2  ,$
  ```

  You would edit this declarations as follows:

  ```
  FIELD=LEAVE_DUE  ,ALIAS='AU,2,P'  ,USAGE=P2  ,ACTUAL=P2  ,$
  ```

- If two or more fields in the Master File are synonyms (they refer to the same field in the data source and, therefore, have the same ALIAS attribute), only the first field encountered in the Master File can be used in INSERT and UPDATE commands. If a synonym other than the first is used in an INSERT command, it is ignored. If one is used in an UPDATE command, processing is terminated with the following error message:

  ```
  (FOC4565) IGNORED ATTEMPT TO CHANGE NONUPDATABLE FIELD
  ```

In the Access File:

- The segment attribute WRITE=YES indicates that values of fields from the segment may be modified.
- If a segment has the attribute ACCESS=ADBS, you can define a unique key by adding the following attribute:

  ```
  UNQKEYNAME=name
  ```

where:

name

Is the name of the elementary or group field to be used as the unique key.

The UNQKEYNAME attribute does not necessarily define the key described in the ADABAS FDT (the UQ option). The adapter uses it to decide which rules to apply in an INSERT, DELETE, or UPDATE command. If the UNQKEYNAME attribute does not correspond to the key described with the UQ option in the ADABAS FDT, Adabas and the adapter may not agree on whether a segment instance is unique. This can affect the results of INSERT commands. If this attribute is not present, the adapter uses the rules for modifying a segment with a non-unique key or no key. If it is present, the adapter uses the rules for modifying a segment with a unique key. Subsequent sections describe these rules.

- We recommend the use of CALLTYPE=FIND instead of CALLTYPE=RL.

When using the Write Adapter for Adabas, the adapter automatically sets the values of the following two options:

- ADABAS OPEN is set to YES.
- FETCH is set to OFF for all segments.

SQL Commands for the Adapter for Adabas

The Adapter for Adabas supports the following commands:

- SQL INSERT
- SQL UPDATE

  Note: Certain types of fields listed in the Master File cannot be updated. For more information, see *Fields That Cannot be Updated* on page 222.

- SQL DELETE

The adapter issues a COMMIT after each INSERT, UPDATE, or DELETE call. If the Adabas process fails, the adapter issues a ROLLBACK. User rollback of the Adabas process is not supported for SQL commands.

Reference: Obtain Counts of Rows Updated or Deleted

While processing SQL transactions, you can issue the PASSRECS command to obtain counts of rows affected by each successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Syntax: How to Count Records Updated, Inserted or Deleted

```
ENGINE ADBSINX INT SET PASSRECS {ON|OFF}
```

where:

`ADBSINX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`INT`

Indicates that the PASSRECS setting in this command will be applied globally to all adapters that support SQL INSERT, UPDATE, and DELETE commands.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.

Reference: Fields That Cannot be Updated

The SQL UPDATE command for the following types of fields is ignored:

- Counter fields (ALIAS=xxC).
- ORDER fields (ALIAS=ORDER).
- Group fields.
- Unique key fields (fields specified by the UNQKEYNAME attributes in the Access File).

The SQL UPDATE command for the following types of fields produces an error:

- Synonym fields.
- Fields created from subdescriptors or superdescriptors (as defined in the Access File).

Reference: **Using Synonym Fields (Not Related to Creating a Synonym)**

In a Master File, two or more field declarations can refer to the same Adabas field. Each duplicate field declaration after the first is called a synonym field. Such synonym fields can be used in report commands, but cannot be used in write commands. The following actions occur as a result of using synonyms in write commands:

- Synonym fields used in SQL INSERT are ignored.
- Synonym fields used in SQL UPDATE cause processing to terminate and generate the message:

  ```
  (FOC4565) IGNORED ATTEMPT TO CHANGE NONUPDATABLE FIELD
  ```

Syntax: **How to Insert Records Into an Adabas Data Source**

```
INSERT INTO mfname [(field1, field2, ...)]
VALUES ('value1','value2', ...)
```

where:

mfname

Is the name of the Master File to use.

field1, field2, ...

Is an optional list of fields to be inserted. If you omit the list, the value list must contain values for all fields in all segments in the Master File as long as the Master File only specifies a single path Adabas file. If the Master File is multi-path, the field list is required and can specify only a single path. Elementary fields not included in the field list have empty values in the data source. The field list can contain only elementary fields. Groups, subdescriptors, superdescriptors, and hyperdescriptors, cannot be used in the field list.

'value1', 'value2',...

Is the list of values to be inserted. Each alphanumeric value must be enclosed in single quotation marks. If you specify the field name list, the value list only needs to specify, in field name list order, the values for the field names supplied. At a minimum, you must supply all the key fields for all the segments in the path to the target.

If a segment is not present, default values are generated for all fields that are not supplied, and the missing path segments are inserted along with the target segment.

Reference: Rules for Inserting Records Into an Adabas Data Source

- For a segment with a unique key:

  The key field value is used to insert the target segment. If any additional fieldname=value pairs are supplied for a segment in the path, they are used to qualify that path segment. If a segment with ACCESS=ADBS has a unique key or group of keys, only these key fields should be used in the INSERT command. All other fields should be added to the record using the UPDATE command.

- For a segment with a non-unique key or no key:

  If you want to insert an additional record for an existing key field, you must have at least one field in addition to the key field in the field list in order to make the record unique. If you do not, the insert is rejected.

- For segments with ACCESS=PE or MU, if a new occurrence is inserted, you must set the occurrence number (ORDER field) to 0 (zero indicates the next occurrence) or to a value greater than the number of existing occurrences. This new occurrence is always inserted after the last existing occurrence. For example, if a PE or MU segment has two existing occurrences, the next occurrence added is always the third. If the occurrence with the given number already exists, processing terminates with the following message:

  ```
  (FOC4564) THIS OCCURRENCE ALREADY EXISTS. USE UPDATE COMMAND
  ```

  You should use the UPDATE command instead of INSERT in this case.

- For segments in which the parent segment contains ACCESS=PE, and the child segment contains ACCESS=MU without the NU option in the ADABAS FDT:

  - If an INSERT command is issued for the parent (PE) segment alone, Adabas automatically inserts an empty child (MU) segment. You can use the UPDATE command to provide values for this child.

  - If one INSERT command is issued for the parent (PE) and child (MU) segments simultaneously, the first occurrence in the child segment is inserted by the Write Adapter for Adabas using the values from the INSERT command.

- For segments in which the parent segment has ACCESS=PE, and the child segment has ACCESS=MU with the NU option in the ADABAS FDT, the empty child is automatically suppressed by Adabas. You can use an INSERT command for the parent and child segments separately or simultaneously.

Reference: Effect of UNQKEYNAME on INSERT Actions

The UNQKEYNAME attribute in the Access File determines how the adapter presents an INSERT command to Adabas. The UQ option in the ADABAS FDT and the specific field values listed in the INSERT command determine whether Adabas actually inserts the segment instance. The following table describes how these factors affect the result of the INSERT command. Assume that the Access File specifies UNQKEYNAME=EMPLOYEE_ID and that the employee ID value EMPID005 already exists in the data source:

Result of the INSERT Command for Existing EMPLOYEE_ID EDMPID005

EMPLOYEE_ID has the UQ Option in FDT	Fields in INSERT Command	Instance Inserted
No	EMPLOYEE_ID only.	No - rejected duplicate
Yes	EMPLOYEE_ID only.	No - rejected duplicate
No	EMPLOYEE_ID plus fields with values that do not already exist.	Yes
Yes	EMPLOYEE_ID plus fields with values that do not already exist.	No - message (FOC4561), RC=198

Result of INSERT Command when EMPLOYEE_ID is not in the field list

UNQKEYNAME = EMPLOYEE_ID	Instance Inserted
Yes	No - message (FOC4563)
No	Yes, with empty EMPLOYEE_ID value.

Syntax: How to Update Field Values in an Adabas Data Source

```
UPDATE mfname SET field1 ='value1' [,field2 ='value2'...]
WHERE kfield1 ='kvalue1' [AND kfield2 ='kvalue2'...]
```

where:

mfname

Is the name of the Master File to use.

field1, field2, ...

Are the names of the fields to be updated.

'value1', 'value2',...

Are the new values for the updated fields, enclosed in single quotation marks.

kfield1, kfield2, ...

Are, at a minimum, all of the key fields for all the segments in the path to the target. Only one target segment is updated. You can include additional fieldname=value pairs for the target or any segment in the path. When additional fieldname=value pairs are present for the target segment, these are used for change verification protocol processing. If all target fieldname=value pairs that are present match the Adabas segment field values, the segment is updated with the SET fieldname values. The field list can contain only elementary fields. Groups, subdescriptors, superdescriptors, and hyperdescriptors, cannot be used in the field list.

'kvalue1', 'kvalue2',...

Are the values that identify the target segment, enclosed in single quotation marks.

Reference: Rules for Updating Records in an Adabas Data Source

- For a segment with a unique key, the key field value and any additional fieldname=value pairs are used to qualify the target segment for an update.
- For a segment with a non-unique key, you must supply the key field. If the WHERE criteria for this type of segment, in the path or target, do not identify a unique occurrence, the first occurrence found is updated. The use of Adabas descriptors for this type of segment is highly recommended for efficiency.
- For a segment with no key, you must supply at least one fieldname=value pair. If the WHERE criteria for this type of segment, in the path or target, do not identify a unique occurrence, the first occurrence found is updated.

Syntax: How to Delete Records From an Adabas Data Source

```
DELETE FROM mfname WHERE field1 ='value1' [AND field2 ='value2'...]
```

where:

mfname

Is the name of the Master File to use.

field1, field2, ...

Are, at a minimum, the names of all of the key fields for all the segments in the path to the target. Only one target segment is deleted; Adabas cascades the delete to dependent segments. Additional fieldname=value pairs may be included for the target segment and any segment in the path that has no key or a non-unique key. It is recommended to use Adabas descriptor fields for any additional fieldname=value pairs.

'value1', 'value2',...

Are the values that identify the target segment to be deleted.

Reference: **Rules for Deleting Records From an Adabas Data Source**

- For a segment with a unique key, the key field value is used to delete the target segment.
- For a segment with a non-unique key, you must supply the key field. If the WHERE criteria for this type of segment, in the path or target, do not identify a unique occurrence, the first occurrence found is deleted. The use of Adabas descriptors for this type of segment is highly recommended for efficiency.
- For a segment with no key, you must supply at least one fieldname=value pair. If the WHERE criteria for this type of segment, in the path or target, do not identify a unique occurrence, the first occurrence found is deleted.
- A segment occurrence with ACCESS=PE or MU is deleted from the data source except if it is the last occurrence for an ACCESS=PE segment. Adabas only deletes the last occurrence if all fields have the NU option in the FDT. If they do not all have this option, the occurrence has empty values in all fields.
- When you delete segments that have dependent segments, the DELETED counter for the session may have an incorrect value. For a first level segment with descendants, this counter is always incorrect. For a second level segment, this counter is incorrect if there are multiple descendant segments. For a third level segment, this counter is always correct.

Adapter Navigation

To retrieve the necessary records that fulfill a request, the Adapter for Adabas navigates the Adabas database through direct calls in read-only mode. The calls generated depend on three factors:

- Information supplied in the Master File.
- Information supplied in the Access File for a specified segment.

- Particulars of the report request.

The adapter uses information from these sources to choose the most appropriate and efficient retrieval method.

There are three logical types of Adabas access:

- Entry segment retrieval of Adabas records.
- Retrieval of descendant periodic groups and multi-value fields.
- Retrieval of descendant Adabas records.

Entry Segment Retrieval of Adabas Records

The server constructs an Adabas request based on the Master File, Access File, and the report request. The root of the subtree is the entry segment into the database for a particular request.

For Adabas structures, the root of the subtree must be a segment in the Access File containing singly occurring fields (ACCESS=ADBS). The Adabas calls generated to retrieve data for this entry segment depend on the Access File information that has been supplied for the segment and the selection tests in the request.

The first decision the Adapter for Adabas makes for the entry segment is whether to retrieve all the records of the segment or just a subset.

All records are retrieved for a segment if either of the following conditions exists:

- There is *no* selection test on any field that is a descriptor (defined in the Access File with TYPE=SPR, DSC, or NOP) and the SEQFIELD has not been defined.
- The specified selection test is *not* IF or WHERE, and does not use the relational operators:

  `IS, EQ, GE, GT, LT, LE, or FROM...TO`

  For example:

  field **IS** *value1* [(OR *value2*... OR *valuen*)]

  field **IS** (*ddname*)

  field **FROM** *value1* **TO** *value2* [(OR *value3* TO *value4*...)]

  field **GE** *value1*

  field **GT** *value1*

```
field LT value1

field LE value1

group EQ 'value1/value2/value3'
```

When you are using one or more of these selection tests against a descriptor, the adapter uses the inverted list to retrieve a subset of the records for the segment.

For example, consider the following selection criterion:

```
field IS value1 [(OR value2... OR valuen)]
```

In this example, any combination of full values or partial values triggers the use of inverted lists except when the $ (used to indicate a masked field) is in the first position of the value. If the $ is in the first position of the value, the search conducted by Adabas is not done through the descriptor's inverted list. Instead, the search is conducted physically through the database in the same manner that a Read Physical call performs a retrieval. See *Read Physical Calls* on page 230 for more information.

Once the adapter determines whether to retrieve all or a subset of the segment records, it decides which access strategy to use based on the Access File attribute settings. The following are the strategies that the adapter can use:

- Retrieval of all records through Read Physical (L2) calls discussed in *Read Physical Calls* on page 230.
- Retrieval of all records through Read Logical (L3) calls without using a starting value discussed in *Read Logical Navigation* on page 231.
- Retrieval of a subset of records through Read Logical (L3) calls using a starting value discussed in *Read Logical Navigation* on page 231.
- Retrieval of all records for the entry segment through Read Logical by ISN (L1) calls discussed in *Read Logical Navigation* on page 231.
- Retrieval of a subset of records through simple FIND (S1) calls discussed in *FIND Navigation* on page 235.
- Retrieval of a subset of records through complex FIND (S1) calls discussed in *FIND Navigation* on page 235.
- Retrieval of all records through Read Descriptor Value (L9) direct calls discussed in *Read Descriptor Value (L9) Direct Calls* on page 238.

The selection logic is designed to implement as many of the record selection tests as possible at the Adabas level. It minimizes the number of I/O operations required to access the necessary data by issuing efficient calls to Adabas.

Read Physical Calls

Read Physical calls read every database record in a physical file, and then return every record for the entry segment to the server. The server must then select the records that meet the selection criteria in the request and discard the rest.

The Adapter for Adabas issues Read Physical (L2) calls to retrieve all records for the entry segment when:

- The request contains no optimizable selection tests on an inverted list (descriptor) and the Access File does not have a SEQFIELD defined.
- With CALLTYPE=FIND, there is no screening on a descriptor, the screening for a non-descriptor has been set off, and the Access File does not have a SEQFIELD defined.

See *Adabas Reporting Considerations* on page 211 for more information about retrieval of records with no screening on a descriptor.

The steps the adapter and Adabas perform to complete a Read Physical call are:

1. The adapter constructs a Read Physical (L2) call.
2. Adabas returns each record in the physical file corresponding to the Adabas file number specified. The records are retrieved in the order in which they are physically stored.

Subsequent retrieval for the entry segment is completed by issuing the same Read Physical call with the User Control Block unmodified. The adapter terminates retrieval when one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached (see *Adabas Reporting Considerations* on page 211 for information about these keywords).

Read Physical (L2) calls can be faster than Read Logical (L3) calls depending on the request and the data dispersion of the physical storage. Ask your Adabas database administrator if you should use SEQFIELD for a given Adabas record, or if Read Physical would be more efficient.

Read Logical Navigation

When designing a database, it is necessary to know the contents of the files being created. Defining descriptors is very important for efficiency. The Adapter for Adabas does not have information about the different fields, or about which field is more efficient to parse first, unless the Access File has this information. The Access File tells the adapter how to access your data in the most efficient manner. The order of the fields (for example, DSC, NOP, or SPR descriptors) is important in the Access File, as the adapter uses this order when executing an IF or WHERE clause.

The Access File needs to have information about the index fields used in the report request. The order in which you define these fields is important. Adabas is field oriented, not positional. The order of the fields will not affect retrieval, except for the selection of which inverted list to use.

The Access File controls the order of the IF or WHERE clauses, so the database administrator can set up the Access File in the order of the most efficient reads. The user will then receive the requested data much more efficiently. The order in the Access File controls the order of retrieval.

Read Logical Calls Without a Starting Value

The Adapter for Adabas uses Read Logical (L3) calls to retrieve all records for the entry segment when the Access File contains a SEQFIELD value for that segment and the report request does not contain an optimizable selection test on an inverted list, and CALLTYPE=RL.

SEQFIELD is generally used to suppress Read Physical calls when there is no optimizable selection test on an inverted list. A Read Physical call will be issued if a SEQFIELD is not defined.

The steps the adapter and Adabas perform to complete a Read Logical call without starting values are:

1. The adapter constructs a Read Logical (L3) call without the 'Value Start' option and without the Adabas Search and Value buffers.
2. Adabas returns each record corresponding to an entry in the inverted list. The records are in the same order as the inverted list.

Subsequent retrieval for the entry segment is done by issuing the same Read Logical call with the User Control Block unmodified. The records are returned in ascending value of the inverted list. The adapter terminates retrieval when one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

In an Adabas file that has no record types, you can select the value of SEQFIELD from any inverted list containing entries for all records on the file.

SEQFIELD is required when the Adabas file has several record types. In this case, the value of SEQFIELD is an inverted list which has entries for a single record type.

If the descriptor used as the SEQFIELD is null-suppressed or contains null-suppressed fields, only records where the descriptor is populated will be included in the retrieval. An entry is not included in the inverted list if a field is null and will not be returned by Adabas to the server. See your Software AG documentation for more information about null-suppression and how it affects data retrieval.

Read Logical Calls With a Starting Value

The Adapter for Adabas constructs Read Logical (L3) calls for the root of the accessed subtree when the following conditions exist:

- The Access File contains CALLTYPE=RL for that segment.
- The request contains an optimizable selection test against a descriptor or superdescriptor identified by TYPE=SPR or DSC in the Access File.
- None of the selection tests is on a field identified by TYPE=NOP in the Access File.

When a report request contains multiple optimizable selection tests, the order of descriptors in the Access File determines the order in which the server applies the selection tests. The server issues a Read Logical (RL) call using the first descriptor listed in the Access File that participates in a selection test.

Therefore, for efficient processing, you should describe the most restrictive descriptor at the beginning of its segment in the Access File. The order of descriptors in the Master File has no effect on selection processing.

The steps Adabas performs to complete a Read Logical call are:

1. The adapter constructs a Read Logical (L3) call with the starting value to be retrieved for that inverted list.
2. The adapter calls Adabas with a 'V' in Command Option 2, which instructs Adabas to use the 'Value Start' option.
3. The call retrieves the first record whose value in the inverted list is equal to or greater than the value specified in the request.

Subsequent retrieval for the entry segment is done by issuing the same Read Logical call with the User Control Block unmodified. The records are returned in ascending value of the inverted list.

The adapter terminates retrieval when one of the following occurs:

- The value of the inverted list is out of range of the request.
- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

If there are multiple values specified in the request (for example, WHERE *field* EQ *value* OR *value*..., WHERE *field* FROM *val1* TO *val2* OR *val3* TO *val4*) and RECORDLIMIT or READLIMIT has not been reached, the Adapter for Adabas releases the Command ID and reissues the Read Logical call with the next starting value. For each set of values, the adapter terminates retrieval when one of the above conditions occurs.

Retrieval Through Read Logical by ISN (L1) Calls

The Adapter for Adabas uses Read Logical by ISN (L1) calls to retrieve all records for the entry segment when the:

- Report request does not contain an optimizable selection test on an inverted list or an ISN list.
- Access File contains a SEQFIELD value for that segment and this value is equal to the ISN field name.

Adabas returns each record corresponding to an entry in the Address Converter. The records are in ascending value of the ISN. For example:

Access File ADATEST

```
SEGNAM=S01, ACCESS=ADBS, ... , SEQFIELD=ISN_FIELD ,$
```

Request

```
SELECT AA_FIELD, AJ_FIELD FROM ADATEST;
```

The adapter uses Read Logical by ISN (L1) calls to retrieve a single record for the entry segment when the:

- Report request contains the only EQ relational operator in the selection test on an ISN list.
- ISN field is used as the cross-referenced field in the Join to Adabas file.

Adabas returns RC 113 if the record with the ISN defined in the test is not present in the Address Converter for the file. Then the adapter returns the answer "Record is not found".

For example:

```
SELECT AA_FIELD, AJ_FIELD FROM ADATEST
WHERE ISN_FIELD = 1100;
```

Note: The Multifetch option will be suppressed for this call.

The adapter uses Read Logical by ISN (L1) calls to retrieve subset of records for the entry segment when the:

- Report request contains the only GE/GT relational operator in the selection test on an ISN list.
- Report request does not contain any selection test on an inverted list.
- Access File contains a SEQFIELD value for that segment.

Adabas returns each record corresponding to an entry in the Address Converter. The records are in ascending value of the ISN.

For example, the Access File ADATEST contains:

```
SEGNAM=S01, ACCESS=ADBS , ... ,SEQFIELD=AA_FIELD ,$
```

Request 1. When Read Logical by ISN (L1) used:

```
SELECT AA_FIELD, AE_FIELD FROM ADATEST
WHERE ISN_FIELD > 1100;
```

Request 2. When Read Logical (L3) used:

```
SELECT AA_FIELD, AE_FIELD FROM ADATEST
WHERE ISN_FIELD > 1100 AND AJ_FIELD = 'TAMPA';
```

After issuing an Insert request to the file with the ISN field in the Master File, the resulting ISN from Adabas is printed in the message FOC4592:

```
(FOC4592) RECORD IS INSERTED WITH ISN : nnnnn
```

For example:

```
SQL
INSERT INTO ADBTEST (AA_FIELD, AJ_FIELD)
VALUES ('11111111', 'TAMPA');
END

ADBTEST ADBSINX ON 09/20/2002 AT 15.22.16
(FOC4592) RECORD IS INSERTED WITH ISN : 11
(FOC4566) RECORDS AFFECTED DURING CURRENT REQUEST : 1/INSERT
TRANSACTIONS: TOTAL = 1 ACCEPTED= 1 REJECTED= 0
SEGMENTS: INPUT = 1 UPDATED = 0 DELETED = 0
```

If the Insert request contains an ISN field in the fields list and a corresponding value is not 0, then the adapter issues an N2 call to Adabas. Adabas assigns this ISN value to the record provided by the user. Adabas returns RC 113 if this value was already assigned to another record in the file or if it is larger than the MAXISN in effect for the file.

For example:

Request 1

```
SQL
INSERT INTO ADBTEST (AA_FIELD, AJ_FIELD, ISN_FIELD)
VALUES ('11111114', 'TAMPA', 14);
END

ADBTEST ADBSINX ON 09/20/2002 AT 15.22.16
(FOC4592) RECORD IS INSERTED WITH ISN : 14
(FOC4566) RECORDS AFFECTED DURING CURRENT REQUEST : 1/INSERT
TRANSACTIONS: TOTAL = 1 ACCEPTED= 1 REJECTED= 0
SEGMENTS: INPUT = 1 UPDATED = 0 DELETED = 0
```

Request 2

```
SQL
INSERT INTO ADBTEST (AA_FIELD, AJ_FIELD, ISN_FIELD)
VALUES ('11111114', 'TAMPA', 999999);
END

ADBEMP43ADBSIN ON 09/19/2002 AT 16.16.22
(FOC4561) ERROR IN ADABAS INCLUDE /113
TRANSACTIONS: TOTAL = 1 ACCEPTED= 1 REJECTED= 0
SEGMENTS: INPUT = 0 UPDATED = 0 DELETED = 0
```

FIND Navigation

The manipulation of ISN lists is done on the initial call to Adabas. Both the intermediate lists and the resulting list may be very large and may take up a large percentage of the Adabas workspace. The Adabas work area is shared by all Adabas users, and complex FINDs may affect programs that are updating the database. You may want to suppress FINDs altogether. Accomplish this suppression by specifying CALLTYPE=RL on every Access File segment. Ask your Adabas database administrator whether to use FIND processing.

Simple FIND Calls

The Adapter for Adabas constructs a simple FIND (S1) call, using a single inverted list structure, for the root of the accessed subtree if one of the following conditions is met:

- The Access File contains either CALLTYPE=FIND for that segment or does not specify the CALLTYPE attribute, in which case the adapter default is CALLTYPE=FIND. Additionally, the request contains a single selection test on a descriptor identified with TYPE=DSC or a superdescriptor identified with TYPE=SPR in the Access File.
- For any value of CALLTYPE (RL or FIND), if the request contains a single selection test on a subdescriptor or superdescriptor containing partial fields (identified with TYPE=NOP in the Access File).

CALLTYPE=FIND instructs the adapter to generate FIND calls to retrieve records from the inverted lists. This method is the default for processing selection criteria on inverted lists for a segment (if CALLTYPE is omitted from the Access File segment declaration).

If you have selected a field defined with TYPE=NOP (for example, subdescriptors), a FIND call is issued even if RL has been specified in cases when:

- SET NOPACCESS FIND was performed.
- The server is running in an OpenVMS environment.
- The same Adabas field is defined in a descendant PE/MU segment.

Switching from RL to FIND mode is also performed if a:

- Field is defined with TYPE=SPR and the server is running in an OpenVMS environment.
- Field is defined with TYPE=PDS (phonetic descriptor) or TYPE=HDS (hyperdescriptor).
- Field is defined in a PE segment (that it is a part of periodic group).

For performance considerations, a FIND (S1) call does not issue a READ ISN (L1) call if an answer set containing only one record is returned. The GET FIRST option returns the first record in the inverted list. This reduces unnecessary I/O calls. If the FIND call returns more than one ISN in a list, the GET NEXT option of L1 is used to start reading the ISN list from the second entry.

The steps Adabas performs to complete a FIND (S1) call are:

1. The adapter constructs a FIND (S1) call with the value(s) specified.
2. The adapter calls Adabas with an 'H' in Command Option 1, which instructs Adabas to store the resulting list of Internal Sequence Numbers (ISNs) in the Adabas work area.

3. Adabas constructs a complete list of ISNs for every record matching the selection criteria in the work area of Adabas. This list is sorted in ascending ISN order.
4. The adapter issues a Read ISN (L1) call to retrieve the first record from the Adabas work area which matches the selection criteria. The records are returned in ascending ISN order.

All subsequent retrieval for this entry segment is done using the Read ISN (L1) call issued against the ISN list held by Adabas. L1 commands are issued until one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

Complex FIND Calls

The Adapter for Adabas constructs complex FIND (S1) calls, using two or more inverted list structures, for the root of the accessed subtree if one of the following conditions is met:

- The Access File contains CALLTYPE=FIND for that segment (or omits CALLTYPE). The request contains multiple selection tests on a descriptor or superdescriptor described with TYPE=DSC or TYPE=SPR in the Access File.
- For any value of CALLTYPE, the request contains selection tests on a subdescriptor or superdescriptor containing partial fields (identified with TYPE=NOP in the Access File).

The steps Adabas performs to complete a FIND call on multiple inverted list structures are:

1. The adapter constructs a FIND (S1) call with all the values specified for each inverted list on which there are selection criteria.
2. The adapter calls Adabas with an 'H' in Command Option 1, which instructs Adabas to store the resulting list of ISNs in the Adabas work area.
3. Adabas constructs an ISN list for each inverted list specified.
4. Adabas merges these lists into a final list of ISNs which match all of the selection criteria in the call. This list is kept in the Adabas work area and is sorted in ascending ISN order.
5. The adapter then issues a Read ISN (L1) call to retrieve the first record from the list in the Adabas work area. The records are returned in ascending ISN order.

All subsequent retrieval for this entry segment is completed using Read ISN (L1) calls issued against the ISN list held by Adabas. L1 commands are issued until one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

Read Descriptor Value (L9) Direct Calls

The Adapter for Adabas issues the Adabas Read Descriptor Value (L9) direct call when you use the COUNT command or SUM CNT.*field* within a report request. L9 calls are, by definition, limited to descriptors defined to the server with the following:

- INDEX=I in the Master File.
- A field type of NOP, DSC, or SPR (defined in the Access File).

L9 calls allow an aggregate ISN count to be returned for each unique value on the inverted list at a cost of only one call per unique value. This technique allows a dramatic efficiency gain over passing each record to the server to process the count.

Selection criteria (for example, WHERE *descriptor* EQ '1234') are passed along with the L9 call to further limit the number of calls. If any non-descriptor fields are mentioned in the TABLE request, a Read Descriptor Value (L9) direct call is not possible and the server uses its own internal count processing. If a BY field is used, it must be the same field or GROUP name used as the object of the COUNT verb.

Here is an example of the SUM CNT.*field* using EMPFILE1:

```
TABLE FILE EMPFILE1
SUM CNT.DEPT_S03
BY DEPT_S03
END
```

Descendant Periodic Groups and Multi-Value Fields

The Adapter for Adabas must retrieve a count of the number of occurrences before attempting to retrieve a periodic group (PE) or multi-value (MU) field. This retrieval is accomplished by taking the appropriate Adabas counter field (indicated by the OCCURS attribute on the segment declaration in the Master File) and placing its ALIAS (the two-character Adabas name of the PE or MU appended with the letter C) in the Format buffer of the call for the parent record fields.

Adabas returns to this counter field the total number of occurrences that exist for the PE or MU.

The adapter retrieves the descendant data in one of the following ways:

- For MU fields or PE groups which do not contain an MU, all the occurrences are retrieved at once. The counter field ALIAS is used without the letter C, to retrieve the entire set of occurrences in one Read ISN (L2) call.

- For PE groups which contain one or more MU fields, the adapter retrieves a single occurrence of all component fields at a time, including the count(s) of the number of MU descendants, if required. For example, a PE group containing an MU field which has five occurrences of the PE requires five Read ISN (L2) calls to retrieve all of them.

Descendant Adabas Records

The access strategy used to retrieve descendant records in a subtree depends on the Access File attributes specified for a given segment and the SEGTYPE attribute in the Master File (or the SEGTYPE created on the cross-referenced segment as the result of a JOIN). In some cases, the selection criteria in a request further affect access strategy for descendant segments.

Descendant records are related to their parents by a field or GROUP in the parent that corresponds to a field or GROUP in the descendant. This relationship is set up either in the Access File using the KEYFLD/IXFLD pair or through the host field/cross-referenced field combination in a JOIN.

The most appropriate access strategy is selected based on the value of CALLTYPE of the descendent segment in the Access File. The three basic strategies used to obtain descendant records are:

- Retrieval of descendant records through Read Logical calls using a starting value.
- Retrieval of descendant records through simple FIND calls.
- Retrieval of descendant records through complex FIND calls.

The CALLTYPE attribute, the KEYFLD/IXFLD attributes, the SEGTYPE, and the TABLE request are the determining factors in the way descendant data is retrieved.

Read Logical Calls Using a Starting Value

The Adapter for Adabas constructs Read Logical (L3) calls for related descendant records of a parent when the following conditions are met:

- The Access File contains CALLTYPE=RL for that segment.
- The IXFLD or JOIN *to* field is described as TYPE=DSC or TYPE=SPR in the Access File.
- No other selection criteria on inverted lists for this segment have selection on a descriptor with TYPE=NOP.

Read Logical processing is performed on a single inverted list only. The steps the adapter performs to complete a Read Logical call using a starting value are:

1. The adapter constructs a Read Logical (L3) call with the value of the KEYFLD from the parent segment for the IXFLD inverted list. This call retrieves the first record whose value in the inverted list is equal to or greater than the value of the KEYFLD.
2. For unique descendants, no additional retrieval is performed on the descendant segment for any given parent. (For an embedded cross-referenced segment, the SEGTYPE is U or KU or the segment was the cross-referenced segment in a unique JOIN.)
3. For non-unique descendants, subsequent retrieval for the entry segment is completed by issuing the same Read Logical call with the User Control Block unmodified. The records are returned in ascending value of the inverted list.

The adapter terminates retrieval when one of the following conditions is met:

- The value of the inverted list is greater than the value of the KEYFLD.
- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

Simple FIND Calls (Descendant Records)

The Adapter for Adabas constructs a simple FIND (S1) call, using a single inverted list, to obtain related descendant records for a parent when one of the following conditions exists:

- The Access File contains CALLTYPE=FIND (or omits CALLTYPE) and the request contains no selection criteria on the descendant segment.
- The Access File contains CALLTYPE=FIND (or omits CALLTYPE) and the request contains selection criteria on the descendant segment and the descendant is unique. (For an embedded cross-referenced segment, the SEGTYPE is U or KU or the segment was the cross-referenced segment in a unique JOIN.)
- For any value of CALLTYPE, IXFLD is described with TYPE=NOP in the Access File and the request contains no selection criteria on the descendant segment.

The steps Adabas performs to complete simple FIND calls against descendant segments are:

1. The adapter constructs a FIND (S1) call with the value of the KEYFLD from the parent segment for the inverted IXFLD list.
2. For unique descendants, Adabas returns the record on the FIND call; no 'H' command is issued to Adabas. Only one call will be issued, and only the first instance of data will be returned.
3. For non-unique descendants, the adapter calls Adabas with an 'H' in Command Option 1, which instructs Adabas to store the resulting list of ISNs in the Adabas work area.

4. Adabas constructs a complete list of ISNs for every record related to the parent record in the work area. This list is sorted in ascending ISN order.
5. The adapter issues a Read ISN (L1) call to retrieve the first record from the Adabas work area which matches the selection criteria.

If the descendant is not unique, subsequent retrieval of records for this descendant segment is completed using the Read ISN (L1) call issued against the ISN list held by Adabas. L1 calls are issued until one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

Complex FIND Calls (Descendant Records)

The Adapter for Adabas constructs a complex FIND (S1) call, using several inverted list structures, to obtain related descendant records for a parent when one of the following conditions is met:

- The Access File contains CALLTYPE=FIND for that segment (or omits CALLTYPE) and the descendant is non-unique. (For an embedded cross-referenced segment, the SEGTYPE is S or KM, or the segment was the cross-referenced segment in a non-unique JOIN.) The report request contains one or more selection criteria on the descendant segment.
- The Access File contains any value of CALLTYPE. The descendant is non-unique. (For an embedded cross-referenced segment, the SEGTYPE is S or KM, or the segment was the cross-referenced segment in a non-unique JOIN.) The request contains one or more selection criteria on the descendant segment, one of which is on a descriptor, or the IXFLD is described as TYPE=NOP in the Access File.

The steps Adabas performs to complete a complex FIND call are:

1. The adapter constructs a FIND (S1) call with the value of the KEYFLD from the parent segment using the inverted IXFLD list, in addition to all other selection criteria on inverted lists from the request.
2. For non-unique descendants, the adapter calls Adabas with an 'H' in Command Option 1, which instructs Adabas to store the resulting list of ISNs in the Adabas work area.
3. Adabas constructs an ISN list for each inverted list specified, and merges these lists into a final list of ISNs that match all of the selection criteria in the call. This list is kept in the Adabas work area and is sorted in ascending ISN order.
4. The adapter then issues a Read ISN (L1) call to retrieve the first record from the Adabas work area which matches the selection criteria.

Subsequent retrieval of records for this descendant segment is done through the Read ISN (L1) call issued against the ISN list held by Adabas. L1 commands are issued until one of the following occurs:

- Adabas issues a response code indicating end-of-list.
- The RECORDLIMIT or READLIMIT is reached.

Chapter 4

Using the Adapter for Adabas Stored Procedures

The Adapter for Adabas Stored Procedures enables you to invoke an Adabas stored procedure, which is a Natural subprogram created and tested using Natural facilities.

Note: This adapter is only available on the z/OS operating systems.

You invoke a stored procedure by:

- Issuing a data retrieval command in an SQL request.
- Issuing a Data Manipulation Language (DML) request. (DML is Information Builders internal retrieval language, TABLE.)
- Executing a remote procedure call.

This enables you to invoke an Adabas stored procedure from environments like WebFOCUS and DataMigrator. You can pass input parameters to a stored procedure by specifying filtering criteria in the request or to an RPC by passing a parameter list. You retrieve output as an answer set.

You use the Web Console or the Data Management Console to generate a synonym for a stored procedure using information from Natural data areas. The synonym maps the input and output parameters of a procedure.

In this chapter:

Preparing the Adabas Stored Procedures Environment

The Adapter for Adabas must be installed and configured prior to configuring the Adapter for Adabas Stored Procedures. For information about configuring the Adapter for Adabas, see *Using the Adapter for Adabas* on page 129.

Configuring the Adapter for Adabas Stored Procedures

You can configure the Adapter for Adabas Stored Procedures from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter

You must have configured the Adapter for Adabas in order to be able to configure the Adapter for Adabas Stored Procedures. For configuration instructions, see *Using the Adapter for Adabas* on page 129.

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note: The Adapter for Adabas Stored Procedures is under the *Procedures* group folder. No input parameters are required.

Managing Adabas Stored Procedure Metadata

When the adapter invokes an Adabas stored procedure, it needs to know where to find the stored procedure and how to process its parameters. For each stored procedure the adapter will access, you create a synonym that describes this information.

Reference: Requirements for Creating a Synonym

Creating a synonym, that is, metadata, for Adabas Stored Procedures consists of mapping input and output parameters that are described in a Natural library as local or global (LDA/GDA) data areas.

Only the first record of a definition can be level 1. If a data area has more than one parameter, the parameters must be defined as a structure.

Example: Defining One Parameter in an Adabas Stored Procedure

```
Local     SAMPPRM1 Library SYSRPC                DBID     3 FNR     8
Command                                                            > +
I T L Name                           F Leng Index/Init/EM/Name/Comment
All - ------------------------------ - ---- -------------------------
    1 PARAMETER                      A   10

------------------------------------------------------------ S 1    L 1
```

Example: Defining Multiple Parameters in an Adabas Stored Procedure

```
Local     SAMPPRM2 Library SYSRPC                DBID     3 FNR     8
Command                                                            > +
I T L Name                           F Leng Index/Init/EM/Name/Comment
All - ------------------------------ - ---- -------------------------
    1 PARAMETERS
    2 TEXTINP                        A   60
    2 TEXTOUT                        A   60
    2 KEYWORD                        A   20 (1:20)

------------------------------------------------------------ S 4    L 1
```

Creating Synonyms

A synonym defines a unique logical name (also known as an alias) for each Adabas stored procedure, and one set of input/output parameters. The adapter requires that you generate a synonym for each Adabas stored procedure that you want to invoke with the adapter.

Synonyms are also useful because they insulate client applications from changes to the location of a procedure. You can move or rename a procedure without modifying the client applications that use it. You need to make only one change, redefining the synonym used by the procedure on the server.

Creating a synonym generates a Master File and an Access File: these are metadata that describe the name, parameters, and options of the Adabas stored procedure to the server.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Adabas Stored Procedure

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Data Base ID

The database ID.

Natural System System File

A number that identifies the Natural System system file.

Natural Stored Procedure Library

Natural library with stored procedure.

Enter a string for filtering library names, inserting the wildcard character (%) at the beginning and/or end of the string.

For example, enter ABC% to display libraries whose names begin with the letters ABC; %ABC to display libraries whose names end with the letters ABC;%ABC% to display libraries whose names contain the letters ABC at the beginning, middle, or end; or % to display all libraries.

Mask for Subprogram Name

The mask for returning a list of subprograms from which to chose. Enter a string for filtering subprogram names, inserting the wildcard character (%) at the beginning and/or end of the string.

Subprogram names

Choose a program from the drop-down list.

To identify the request buffer for the stored procedure, enter values for the next three parameters:

Data Base ID

The database ID.

Natural System User File

A number that identifies the Natural System user file.

Mask for the Libraries

The mask for returning a list of libraries from which to chose the one containing local/global data areas that describe the parameters of the stored procedure.

Mask for the Data area names

Enter the mask for returning a list of the data areas from which you will chose the data area defining the stored procedure parameters.

Natural Libraries

Select a library from the drop-down list.

Trigger File Data Base ID

The trigger file database ID.

Trigger File Number

The trigger file number.

Transaction Option

Specifies the stored procedure transaction property.

Parameter Option

Specifies the type of parameters the stored procedure has: no parameters, control, or error message.

Synonym name

The name of the synonym. You can retain the current name or change it.

Changing a synonym name enables you to manage multiple synonym versions to reflect, for example, multiple environments, or synonyms with different application logic such as different sets of Master File DEFINE attributes.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Providing a suffix enables you to manage multiple synonym versions to reflect multiple environments, or synonyms with different application logic such as different sets of Master File DEFINE attributes.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Input Data Area/ Output Data Area

Specifies which data areas are for input parameters and which are for output parameters. You can specify the same data area as the source of both the input and output parameters.

You can specify a data area only if Parameter Option is set to a value other than None.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Example: Generating a Synonym

The following sample Master File and Access File are generated from the Web Console using the Create Synonym facility.

Generated Master File SAMP_LEM.MAS

```
FILENAME=SAMP_LEM, SUFFIX=ADANAT  , $
  SEGMENT=SEG1, SEGTYPE=S0, $
$  GROUP=REC_BUFFER, USAGE=A49, ACTUAL=A28, $

```

Reference: Master File Attributes

The following Master File attributes describe Adabas Stored Procedure data segments.

Attribute	Description
FILENAME	The Master File name. This name may or may not match the stored procedure name.
SUFFIX	Identifies the adapter, and is always ADANAT.
SEGMENT	The segments in the description that are created when the synonym is generated. The segment names follow a logical format to provide uniqueness within the file.
FIELDNAME	The field name from the data area.
GROUP	The fields from the data areas that were redefined or that were defined as arrays.

Attribute	Description
USAGE	The display format and length of the field. This attribute determines how the value is displayed in reports. Values are determined based on the format and length specified by the ACTUAL attribute.
ACTUAL	The format and length of the field as described in the data area.

Reference: Access File Attributes

Attribute	Description
SEGNAME	The name of the Master File segment that describes the stored procedure input parameters. If the stored procedure does not have input parameters, the synonym generation process creates a dummy segment.
STPNAME	The name of the stored procedure. You specify the value when you create the stored procedure synonym.
TRGDBID	The database ID of the trigger. You specify the value when you create the stored procedure synonym.
TRGFILE	The name of the trigger file. You specify the value when you create the stored procedure synonym.
OPTTRN	The transaction option. You specify the value when you create the stored procedure synonym.
OPTPRM	The parameter option. You specify the value when you create the stored procedure synonym.
OPTUPD	The update option. This is based on values that you specify when you create the stored procedure synonym.

Invoking an Adabas Stored Procedure

To invoke an Adabas stored procedure, you issue a Data Manipulation Language (DML) request, also known as a TABLE command, or an SQL SELECT statement. (DML is Information Builders internal retrieval language.) For information about the Data Manipulation Language, see the *Stored Procedure Reference* manual.

Syntax: How to Invoke an Adabas Stored Procedure Using TABLE

The syntax for invoking an Adabas stored procedure using a TABLE command is

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the Adabas stored procedure you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

IF/WHERE

Is used if you want to pass values to input parameters.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

Syntax: How to Invoke an Adabas Stored Procedure Using SELECT

The syntax for invoking an Adabas stored procedure using a SELECT statement is

```
SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the Adabas stored procedure you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

WHERE

Is used if you want to pass values to input parameters.

You must specify the value of each parameter on a separate line.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

Syntax: How to Invoke an Adabas Stored Procedure Using EX

```
EX [app_name_space/]synonym  1=parm1_val,..., N=parmN_val

EX [app_name_space/]synonym parm1_name=parm1_val,... ,
                            parmN_name=parmN_val

EX [app_name_space/]synonym [, parm1_val [,...[, parmN_val]]]
```

where:

app_name_space

Is the apps directory name under which the synonyms are stored. This value is optional.

synonym

Is the user friendly name of a repository entry that represents the object to be executed in the vendor environment.

parm_name

Is the name of the parameter taken from the input metadata description.

1=parm1_val

N=parmN_val

parm1_name

parm1_val

parmN_val

Are the parameter values that match the input metadata description.

Note:

- Consecutive commas denote missing parameters in the positional form of the request.
- Values containing special characters (<equal sign> <space> <comma>) must be encapsulated in double or single quotation marks.

Example: Invoking the SAMP_LEM Adabas Stored Procedure

The following TABLE command invokes the SAMP_LEM Adabas stored procedure, passing three parameter values to it.

```
TABLE FILE SAMP_LEM
   PRINT #REF_RC SEG4.#FCHAR
   IF #REF_NAME EQ '12345678'
   IF #REF_COUNT EQ 123
   IF #RESET_PARM EQ 'RESET'
END
```

The following SELECT command invokes the SAMP_LEM Adabas stored procedure:

```
SQL
SELECT #REF_RC SEG4.#FCHAR FROM SAMP_LEM
   WHERE #REF_COUNT = 123
END
```

The following EX commands invoke the SAMP_LEM Adabas stored procedure:

```
EX SAMP_LEM 225,2004
EX SAMP_LEM AM=225,YEAR=2004
EX SAMP_LEM 1=225,2=2004
```

Chapter 5

Using the Adapter for Alchemy Sentiment Analysis

This section describes how to configure the Alchemy Sentiment Analysis Adapter.

In this chapter:

Alchemy Sentiment Analysis Adapter Overview

The Alchemy Sentiment Analysis Adapter is used to score structured and unstructured textual content by identifying positive, neutral, and negative sentiment found within emails, documents, and database records. Textual data from a data source is passed to the adapter in one of three ways:

- Joining the column containing the textual data from the data source to the column within the Alchemy Sentiment Analysis Adapter used to define the textual data to be scored.
- A report which uses Cluster Join metadata. The Cluster Join metadata already contains the join from the column containing the textual data from the data source to the column within the Alchemy Sentiment Analysis Adapter used to define the textual data to be scored.
- Using a WHERE/IF condition to pass textual data directly to the column within the Alchemy Sentiment Analysis Adapter used to define the textual data to be scored.

The score returned from the Alchemy Sentiment Analysis Adapter ranges from -1 to 1.

- A score of -1 identifies the sentiment of the textual data that was passed to the adapter as extremely negative.
- A score of 0 identifies the sentiment of the textual data that was passed to the adapter as neutral.
- A score of 1 identifies the sentiment of the textual data that was passed to the adapter as tremendously positive.

Configuring the Alchemy Sentiment Analysis Adapter

The Alchemy Sentiment Analysis Adapter is part of the Social Media group of adapters within the WebFOCUS Reporting Server.

Procedure: How to Configure the Alchemy Sentiment Analysis Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

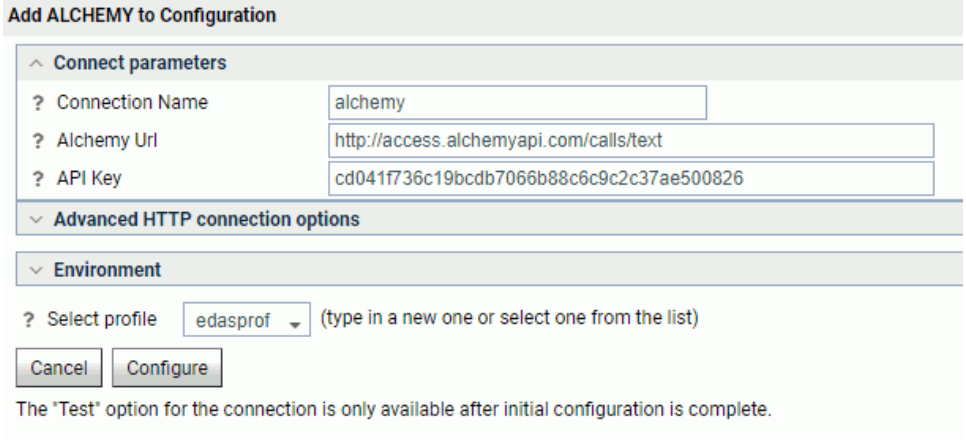
   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click *ALCHEMY* and select *Configure*.

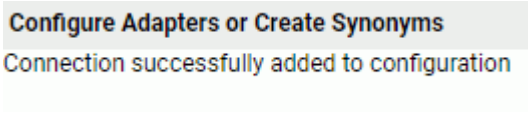
   The Add ALCHEMY to Configuration pane opens, as shown in the following image.



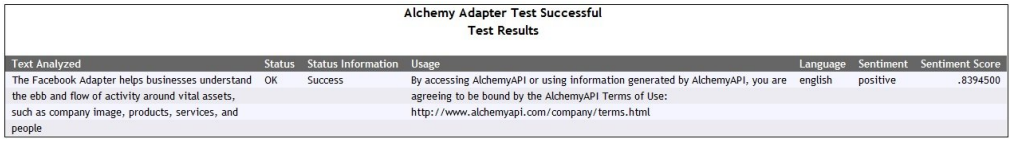
5. Enter the value for API Key supplied by Alchemy.

6. Click *Configure*.

The Configure Adapters or Create Synonyms pane opens, as shown in the following image.



7. Click *Test* to ensure that the Alchemy Sentiment Analysis Adapter is configured properly.



Alchemy Adapter Test Successful
Test Results

Text Analyzed	Status	Status Information	Usage	Language	Sentiment	Sentiment Score
The Facebook Adapter helps businesses understand the ebb and flow of activity around vital assets, such as company image, products, services, and people	OK	Success	By accessing AlchemyAPI or using information generated by AlchemyAPI, you are agreeing to be bound by the AlchemyAPI Terms of Use: http://www.alchemyapi.com/company/terms.html	english	positive	.8394500

Reference: Connection Attributes for Alchemy Sentiment Analysis

The following list describes the connection attributes for the Alchemy Sentiment Analysis Adapter.

Connection Name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Alchemy URL

The URL that is used to connect to the Alchemy Sentiment Analysis service. The default value is:

`http://access.alchemyapi.com/calls/text`

API KEY

The API Key that is supplied by Alchemy to allow authorization to the Alchemy Sentiment Analysis scorer.

PROXY Server IP Address

IP address of the proxy server. For example:

`170.115.249.42`

PROXY Port

Port number on which the proxy server listens. The default port number is 80.

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the connection attributes. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

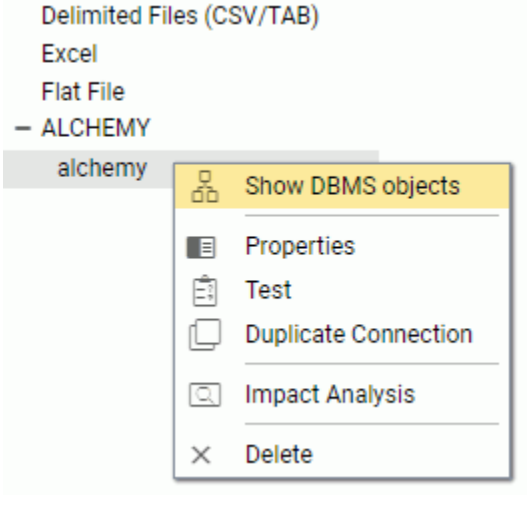
Store the connection attributes in the server profile (edasprof).

Creating Metadata and Sample Reports for the Alchemy Adapter

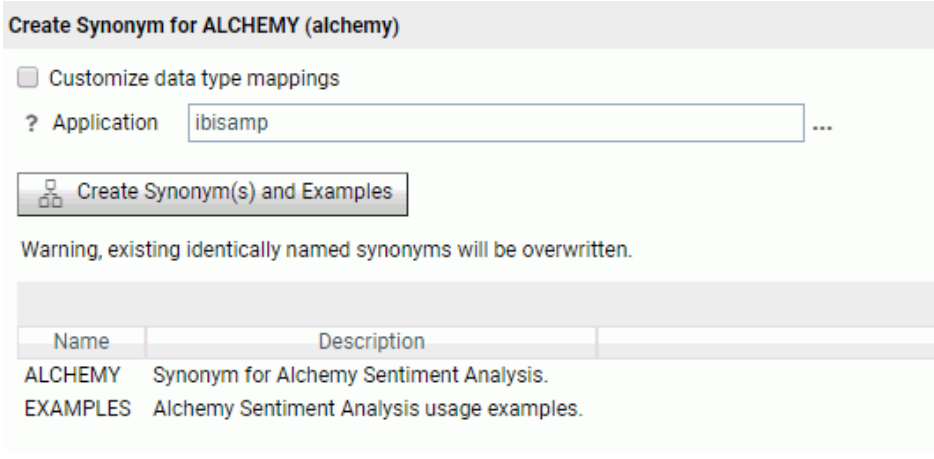
Create Synonym for the Alchemy Sentiment Analysis Adapter creates the metadata used by reports to perform Sentiment Analysis scoring as well as sample reports which utilize the metadata.

Procedure: How to Create Metadata and Sample Reports

1. From the WebFOCUS Reporting Server Web Console or the Data Management Console, expand the *Adapters* folder, *Configured* folder, and then the *ALCHEMY* folder.
2. Right-click the configured connection for the Alchemy Sentiment Analysis Adapter (for example, alchemy) and select *Show DBMS objects* from the context menu, as shown in the following image.



The Create Synonym for ALCHEMY pane opens, as shown in the following image.

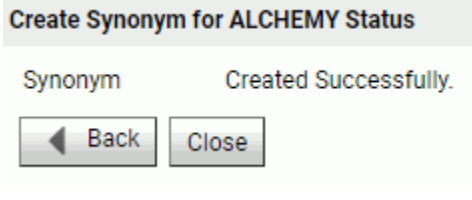


3. Enter a specific application in the Application field or click the ellipsis button to the right of the field to select an application where the metadata and sample reports are to be stored.

   The sample reports are stored within the *alchsampl* subdirectory of the application.

4. Click *Create Synonym(s) and Examples*.

   The Create Synonym for ALCHEMY Status pane opens and indicates that the synonym was created successfully, as shown in the following image.



Alchemy Sentiment Analysis Adapter Examples

This section describes the metadata and sample reports for the Alchemy Sentiment Analysis Adapter.

Reference: Alchemy Sentiment Analysis Adapter Metadata

The following table lists and describes the available metadata for the Alchemy Sentiment Analysis Adapter.

Metadata	Description

alchemy	Metadata is used for interacting with the Alchemy web service for sentiment analysis scoring.
	
	The DOC field would contain the textual data that is to be analyzed and scored by the Alchemy Sentiment scorer. Textual data can be joined from a column within a table to the DOC field or set within a WHERE/IF condition.
	
	The following example uses a JOIN statement:
	
	`JOIN DOCLINE IN alchemy/alchsampl/ alchemy_sample_fix TO DOC IN alchemy/ alchemy END`
	
	The following example uses a WHERE/IF condition:
	
	`WHERE (DOC CONTAINS 'The Facebook Adapter helps businesses')`
	
	A sentiment score between -1 and 1 is returned within the SCORE field.

alchsampl/alchemy_sample_fix	Metadata that defines the sample text file (alchsampl/alchemy_sample.txt) used for the *alchemy_sample_join* and *alchemy_sample_cluster* sample reports.
alchsampl/alchemy_sample_cluster	Cluster join between *alchsampl/alchemy_sample_fix* and *alchemy*.

Reference: **Alchemy Sentiment Analysis Adapter Sample Reports**

The following table lists and describes the sample reports for the Alchemy Sentiment Analysis Adapter.

Sample Report	Description
alchsampl/alchemy_sample_join	Scores the text passed from the *alchsampl/alchemy_sample.txt* file performed through a JOIN statement.
alchsampl/alchemy_sample_cluster	Scores the text passed from the *alchsampl/alchemy_sample.txt* file using the Cluster Join master.
alchsampl/alchemy_sample_where	Scores the text passed within a WHERE statement.

Chapter 6

Using the Adapter for Amazon Athena

The adapter for Amazon Athena allows applications to access and analyze data stored in the Amazon Simply Storage Server (Amazon S3) using standard SQL.

In this chapter:

Introducing the Adapter for Amazon Athena

Amazon Athena is an interactive query service that makes it easy to analyze data directly in Amazon S3 using standard SQL. You can point Athena at your data stored in Amazon S3, run a SQL or ad-hoc query and get results fast.

The Adapter for Amazon Athena is available in two types: ODBC and JDBC. Only one type per server instance can be configured. Amazon provides ODBC (on Windows and Linux) and JDBC drivers and adapter of corresponding type using ODBC or JDBC Athena API to connect and report.

Preparing the Amazon Athena Environment

The following components are needed to use the adapter for Amazon Athena:

ODBC Driver:

- Download and install the Amazon Athena ODBC driver.
- Perform the configuration steps according to the Amazon/Simba instructions for your operating system.
- Obtain the AWS Region, S3 Output Location, Encryption Option, AWS access key, and AWS secret key from your Amazon Athena Administrator.

JDBC Driver:

- Download and install the Amazon Athena JDBC driver.
- Obtain the path to the JDBC driver jar files that you will use. For example, using JDBC 4.1 that is Java 8 compatible on Linux requires:

  ```
  /qas/authena/AthenaJDBC41-1.0.1.jar
  ```

  This full path to the Athena driver .jar files value will be added to IBI_CLASSPATH during configuration.
- Obtain the connection URL, S3 staging directory, AWS access key and AWS secret key from your Amazon Athena Administrator.

Configuring the Adapter for Amazon Athena

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Amazon Athena ODBC Adapter Configuration Settings

The Adapter for Amazon Athena ODBC is under the SQL group folder. The configuration settings for the adapter are:

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

DSN-less

Select this option to provide AWS Region and S3 Output Location in lieu of a DSN.

DSN

The DSN that was configured for your Athena Data Source.

Security

Select *Explicit* as the authentication method to use when connecting to the database server.

User

Enter the AWS access key as the primary authorization ID.

Password

Enter the AWS secret key as the password associated with the primary authorization ID.

Reference: Amazon Athena JDBC Adapter Configuration Settings

The Adapter for Amazon Athena is under the SQL group folder. The configuration settings for the adapter are:

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Is the URL to the location of the Amazon Athena JDBC data source.

The following is an example of the URL that is used to connect to your Amazon Athena server:

```
jdbc:awsathena://connection_URL:?s3_staging_directory
```

where:

connection_URL

Is the connection URL obtained by your Amazon Athena administrator.

s3_staging_directory

Is the staging directory obtained by your Amazon Athena administrator.

Security

Select *Explicit* as the authentication method to use when connecting to the database server.

User

Enter the AWS access key as the primary authorization ID.

Password

Enter the AWS secret key as the password associated with the primary authorization ID.

Driver Name

Enter *com.amazonaws.athena.jdbc.AthenaDriver* as the name of the JDBC driver.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Enter the full path to the Athena driver jars, as determined in *Preparing the Amazon Athena Environment* on page 265.

Creating Synonyms With Amazon Athena

Synonyms define unique names (or aliases) for each Amazon Athena external table (External Table is the only object type that is available in Athena) that is accessible using a connection. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Athena external table.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter and a connection.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.
5. Optionally, expand the *Customize data type mappings* section and enter a value for Longchar Length or numeric precision.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Limitations

Athena uses an approach known as schema-on-read, which means a schema is projected on to your data at the time that you execute a query. This eliminates the need for data loading or transformation. Athena does not modify your data in Amazon S3, but instead uses Apache Hive to define tables and create databases, which are essentially a logical namespace of tables.

When you drop a table in Athena, only the table metadata is removed; the data remains in Amazon S3.

Chapter 7

Using the Adapter for Amazon Redshift

The Adapter for Amazon Redshift allows applications to access Amazon Redshift data sources. The adapter converts data or application requests into native Amazon Redshift SQL statements and returns optimized answer sets to the requesting program.

In this chapter:

Introducing the Adapter for Amazon Redshift

The Adapter for Amazon Redshift is ODBC based. It utilizes the Amazon Redshift ODBC driver, which can be installed on Windows and Linux.

Preparing the Amazon Redshift ODBC Environment

On Windows, the Amazon Redshift ODBC environment is set up during the installation of the Redshift ODBC driver. No additional setup steps are required.

On Linux, after the Amazon Redshift ODBC driver is installed, make sure that path to the directory where the Redshift driver is installed is included in LD_LIBRARY_PATH (or in IBI_LIBPATH if the server is running with security on).

For example:

```
export IBI_LIBPATH=/opt/amazon/redshiftodbc/lib/64
```

Also, set variable AMAZONREDSHIFTODBC that points to the Linux driver manager initialization file with the setting DriverManagerEncoding=UTF-16 in it.

For example:

```
export AMAZONREDSHIFTODBC=/usr/odbc/ibiodbc/amazon.redshiftodbc.ini
```

Configuring the Adapter for Amazon Redshift

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Amazon Redshift Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Amazon Redshift Adapter Configuration Settings

The Adapter for Amazon Redshift is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

System

Is the name of the machine where the Amazon Redshift database is running. The basic syntax is *host*. Note that the port can be specified in the Additional connection string keywords text box.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.
- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Additional connection string keywords (optional)

Is used to add options to the connection string. For example, 'PORT=1563'.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Creating Synonyms With Amazon Redshift

Synonyms define unique names, or aliases, for each Amazon Redshift table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Amazon Redshift table.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Using Direct Pass-through With Amazon Redshift

Direct Pass-through commands, such as SHOW TABLES and DESCRIBE tablename, do not display any results.

This can be avoided by adding a comment:

```
SQL SQLRDS /*QUERY*/ show all;
END
```

Chapter 8

Using the Adapter for Apache Drill

Apache Drill is a query engine for Hadoop and a variety of NoSQL databases and file systems including HDFS and Mapr-FS, HBase and MapR-DB, and MongoDB. Drill can use Hive metadata or derive metadata from self-describing data files.

In this chapter:

Preparing the Apache Drill Environment

The following components are needed to use the adapter for Apache Drill:

- **Java.** To use this Java-based adapter, you must have Java installed. Drill requires Version 1.7 or later. Java can be downloaded from *http://www.java.com*.

  The location of the Java must be specified in an environment variable.

  If you are using Linux, add a line to your profile with the location where Java is installed. For example:

  ```
  export JAVA_HOME=/usr/lib/jvm/jre-1.7.0
  ```

  If you have JDK installed:

  ```
  export JAVA_HOME=/usr/lib/jvm/jdk-1.7.0
  ```

  If you are using Windows, right-click *Computer* and select *Properties*. Then select *Advanced System Settings* and click *Environment Variables*. Add the locations to your PATH variable. For example:

  ```
  C:\Program Files\Java\jdk7\bin\server;C:\Program Files\Java\jdk7\bin;
  ```

- **JDBC Drivers**

  There are two JDBC drivers available for Apache Drill.

  The Open Source JDBC Driver is included with Drill. It consists of a single file that can be found after installation at the following location:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-1.12.0.jar
```

It can also be downloaded from *https://drill.apache.org/docs/using-the-jdbc-driver*.

If you are using the Open Source JDBC Driver and are installing the server on the same system where Drill is installed, you can point to the jar files as described in the next section. If you are installing the server on some other system, copy those files to a location of your choice.

The MapR JDBC driver is available from MapR, as explained in step 3 of the following procedure. This driver also supports MapR SASL authentication.

Procedure: How to Configure the Java CLASSPATH

The location of the Drill jar files must be specified to the server. If you are running the server on the same system as a drillbit, you can specify its location. If you are running the server on another system, copy the files listed below to some location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, select *Workspace*

   or

   From the Data Management Console, expand the *Workspace folder*.

2. Expand the *Java Services* folder, then right-click *DEFAULT*, and select *Properties*.

   The Java Services Configuration page opens.

3. Click on the chevrons to expand Class Path.

   For the Open Source JDBC Driver

   In the IBI_CLASSPATH box, enter the full location of the jar file. For example:

   ```
   /opt/drill/apache-drill-1.12.0/jars/jdbc-driver/drill-jdbc-
   all-1.12.0.jar
   ```

   If you want to access data stored in HBase or MapR-DB, add an additional jar file. For example:

   ```
   /opt/drill/apache-drill-1.12.0/jars/3rdparty/hadoop-common-2.7.0.jar
   ```

   Note: The file names must be entered one per line.

If you are installing the adapter on a different system than where you have Drill installed, copy the jar files to a location on that system.

Note: For a server running on Windows, use Windows syntax for directory names. For example:

```
C:\Drill\jars\jdbc-driver\drill-jdbc-all-1.12.0.jar
```

For the MapR (Simba) JDBC Driver

Download the The MapR JDBC Driver from *https://maprdocs.mapr.com/home/Drill/drill_jdbc_connector.html* from the link for the Drill JDBC Driver provided by MapR. This will download a file named:

```
MapRDrillJDBC41-1.5.8.1017.zip
```

Note: The numbers will change with new releases.

Unzip the file to a location on your server. The 46 jar files constitute the MapR Drill JDBC Driver.

Add the names of all the jar files to your CLASSPATH or IBI_CLASSPATH, as described above.

4. Scroll down and click the *Save and Restart Java Services* button.

Configuring the Adapter for Apache Drill

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Apache Drill Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

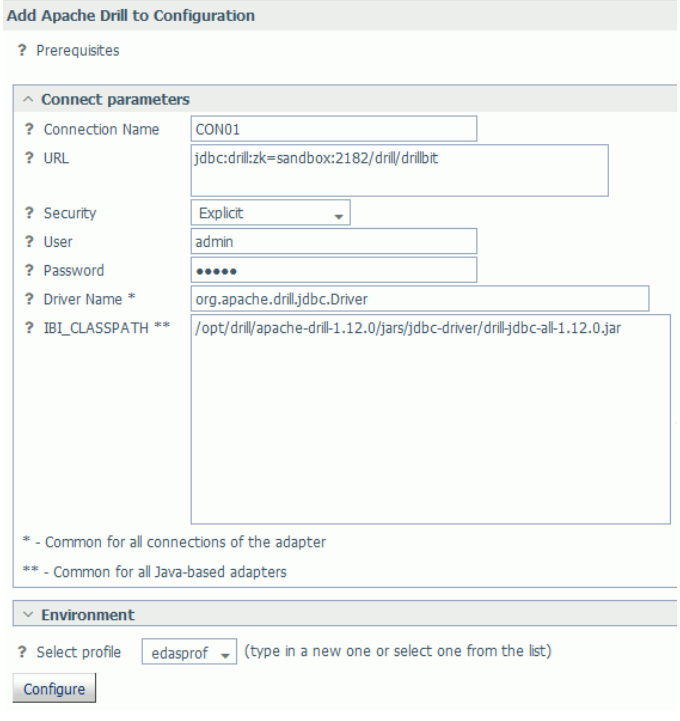
   The Add Adapter to Configuration pane opens.
5. In the URL box, enter the URL used to connect to your Drillbit. For more information, see *Apache Drill URL Configuration Settings*.
6. In the Driver Name box, type the JDBC driver that you are using from the following table:

   `org.apache.drill.jdbc.Driver`

Adapter	JDBC Driver Name
Apache Hive	`org.apache.drill.jdbc.Driver`
MapR Drill	`com.mapr.drill.jdbc41.Driver`

7. Enter your User and Password.

   The following image shows an example of the configuration settings used:



8. Click *Test*. You should see a list of data sources on your server.
9. Click *Configure*.

Reference: Connection Attributes for Apache Drill

The Adapter for Apache Drill is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the Apache Drill data source.

Driver Name

Name for the Apache Drill driver.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.
- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Reference: Apache Drill URL Configuration Settings Using the Open Source rill JDBC Driver

The Adapter for Apache Drill is under the SQL group folder.

The URL configuration for the Apache Drill adapter is:

`jdbc:drill:zk=`*`quorum`*`:`*`port`*`/`*`directory`*`/`*`cluster_id`*`[;schema=`*`schema`*`]`

where:

`quorom`

Is the name or IP address where the Drillbit server is running.

`port`

Is the port number for zookeeper. The default value is 2181. On a MapR cluster, the default value is 5181.

Multiple quorum:port values can be comma separated.

`directory`

Is the name of the drill directory within zookeeper. The default value is drill.

`cluster_id`

Is the name of the drill cluster. The default value is drillbit1.

`schema`

Is the name of the default schema to use, for example, hive.

Reference: Apache Drill URL Configuration Settings Using the MapR JDBC Driver

The Adapter for Apache Drill is under the SQL group folder.

The URL configuration string for a client to Drillbit connection is:

```
jdbc:drill:drillbit=host[:port][:auth=method[:delegationuid=id]
```

where:

host

Is the name or IP address where the drillbit is running.

port

Is the drillbit port. The default value is 31010.

The URL configuration string for a client to Zookeeper connection is:

```
jdbc:drill:zk=quorom[:port]/drill/[cluster]
[:auth=method[:delegationuid=id] ]
```

where:

quorom

Is the name or IP address where Zookeeper is running.

port

Is the Zookeeper port. The default value is 5181 for a MapR cluster.

cluster

Is the name of the drillbit cluster.

For either connection:

method

Is the authentication method. Values are plain, kerberos, or maprsasl.

id

Specifies the user ID it is connected to, when the authentication method is maprsasl.

Troubleshooting

If the server is unable to configure the connection, a dialog box opens with an error message. The message typically begins with the following:

```
(FOC1400) SQLCODE IS -1 (HEX: FFFFFFFF) XOPEN: nnnn
```

where:

nnnn

Is the message number returned.

Some of the more common errors are:

```
(FOC1500) : (-1) [00000] JDBFOC>> connectx():
(FOC1500) : java.lang.UnsupportedClassVersionError:
org/apache/drill/jdbc/Driver :
(FOC1500) : Unsupported major.minor version 51.0
(FOC1479) ERROR CONNECTING TO SQL DATABASE
```

This indicates that your Java version is less than 1.7 which is required for Drill.

Creating Synonyms With Apache Drill

Synonyms define unique names, or aliases, for each Hive table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Hive table.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter and a connection.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

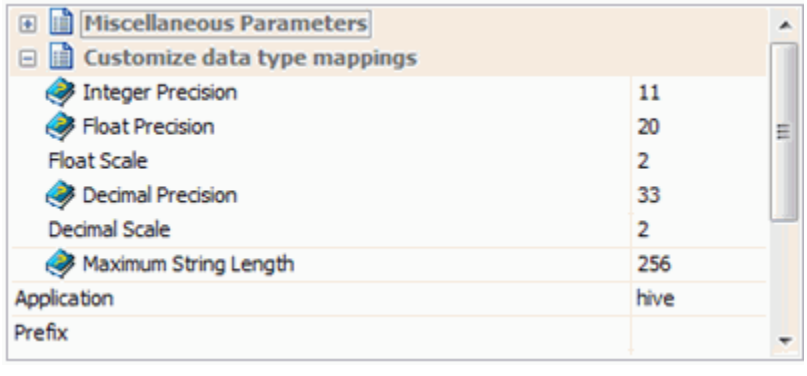
   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.

- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.
5. Optionally, expand the *Customize data type mappings* section and enter a value for Maximum String Length or numeric precision, as shown in the following image.



6. Select the check box for the objects that you want to create synonyms for. If you want to change the name of the synonym from the default name, click the name and edit it as needed.
7. Click *Create Synonym*.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Reference: Synonym Creation Parameters for Apache Drill

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Chapter 9

Using the Adapter for Apache Hive to Access Data Managed by Hadoop

The adapter for Hadoop provides for analysis of both structured and complex data. Hive provides a JDBC driver and the Hive Query Language, a SQL-like interface for generating MapReduce programs.

In this chapter:

Introducing the Adapter for Apache Hive

Hadoop is a collection of open source products and technologies administered by the Apache Software Foundation. It provides for analysis of both structured and complex data. The core components of Hadoop are Hadoop DFS (Distributed File System) and the MapReduce programming framework. Hadoop is available from Apache, as well as many commercial and community distributions. The leading vendors are Cloudera, Hortonworks, and MapR.

Hadoop is designed to run on Linux and is available from many distributors. There is a Windows version available from Microsoft and Hortonworks that runs on Windows Server 2012 R2.

Hive provides a JDBC driver and the Hive Query Language, a SQL-like interface for generating MapReduce programs. While Hive was originally designed for batch processes, it can now be used for reporting and Business Intelligence. For use with WebFOCUS, Hive 1.0 or later is recommended.

Some database vendors provide their own Hadoop distributions with their proprietary SQL engines. This includes IBM Big SQL, MS SQL Server PolyBase, and others. If you are using one of these vendor products in addition to using the Apache Hive adapter, you can also use the Information Builders data adapter for the appropriate product.

The Hive adapter is JDBC based. The DataMigrator or WebFOCUS server can be run on any platform (including Windows) that connects to the server where Hive is running.

Preparing the Apache Hive Environment

The following components are needed to use the adapter for Hadoop/Hive:

- **Java.** To use this JDBC-based adapter, you must have Java installed. Version 1.8 or later is recommended. Java can be downloaded from *http://www.java.com*.

  The location of Java must be specified in an environment variable.

  If you are using Linux, add a line to your profile with the location where Java is installed. For example:

  ```
  export JAVA_HOME=/usr/lib/jvm/jre-1.8.0
  ```

  If you have JDK installed:

  ```
  export JAVA_HOME=/usr/lib/jvm/jdk-1.8.0
  ```

  If you are using Windows, right-click *Computer* and select *Properties*. If using Windows 10, click *Settings* in the Start menu and search for *Environment*. Click *Edit the system environment variables* to open the System Properties dialog box. Click the *Advanced* tab and click *Environment Variables*. Add the locations to your PATH variable. For example:

  ```
  C:\Program Files\Java\jdk8\bin\server;C:\Program Files\Java\jdk8\bin;
  ```

- **JDBC Drivers.** The Apache JDBC driver is distributed as a jar file, which is included in a Hadoop distribution. If you are installing the server on a node or an edge node of your Hadoop cluster, you can point to the hive-jdbc-<*version*>-standalone.jar file as described in the next section. If you are installing the server on some other system, copy the file to a location of your choice.

  If you are using the Cloudera/Simba JDBC driver, download the driver as described in step 3 below.

Procedure: How to Configure the Java CLASSPATH

The location of the Hadoop and Hive jar files must be specified to the server. If you are running the server on a node or an edge node of your Hadoop cluster, you can specify their location. If you are running the server on another system, copy the files listed below to some location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, select *Workspace*

   or

   From the Data Management Console, expand the *Workspace folder*.

2. Expand the *Java Services* folder. Right-click *DEFAULT* and click *Properties*.

   The Java Services Configuration page opens.

3. Expand *Class path*.

   In the IBI_CLASSPATH box, enter the full location of the Hive and Hadoop files shown below, where hive_home is where Hive is installed and hadoop_home is where Hadoop is installed. You must type them explicitly and cannot use $HIVE_HOME. The file names must be entered one per line.

   If you are installing the adapter on a different system than where Hadoop and Hive are installed, copy the jar files to a location on that system.

   Note: For a server running on Windows, use Windows syntax for directory names. For example:

   ```
   C:\jdbc\hive-jdbc-<version>-standalone.jar
   ```

   For Apache Hive:

   Enter the full path to the location of the JDBC client jar on your system:

   ```
   hive-jdbc-<version>-standalone.jar
   ```

   The following jar files may also be required when using the HTPP transport, connecting to a Kerberos enabled cluster, or using HBase as a source.

   ```
   hadoop-common.jar
   hadoop-auth.jar
   ```

   For Cloudera/Simba:

   1. Download the JDBC driver from Cloudera from the Downloads page at *http://www.cloudera.com/downloads.html*.
   2. From the Database Drivers section of the page, click the *Hive JDBC Driver Downloads* link.
   3. Select your operating system and version from the drop-down menus, and click *Get It Now*.

This downloads a file called hive_jdbc_2.5.20.zip, which contains two .zip files. (Note that these numbers will change with each new release.) Unzip the Cloudera_HiveJDBC41_2.5.20.*nnnn*.zip to a location on your system.

Note: The 41 in the file name indicates JDBC 4.1, which supports Java 1.7 or later.

These 15 jar files comprise the Cloudera/Simba JDBC driver. Add the names of all of them to your CLASSPATH or IBI_CLASSPATH, as described above in this step.

4. Scroll down and click the *Save and Restart Java Services* button.

Configuring the Adapter for Hadoop/Hive

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. The adapter supports Hiveserver2, which is available in Hive 0.11.0 and later. It is strongly recommended for improved throughput, functionality, and security.

Procedure: How to Configure the Hadoop/Hive Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

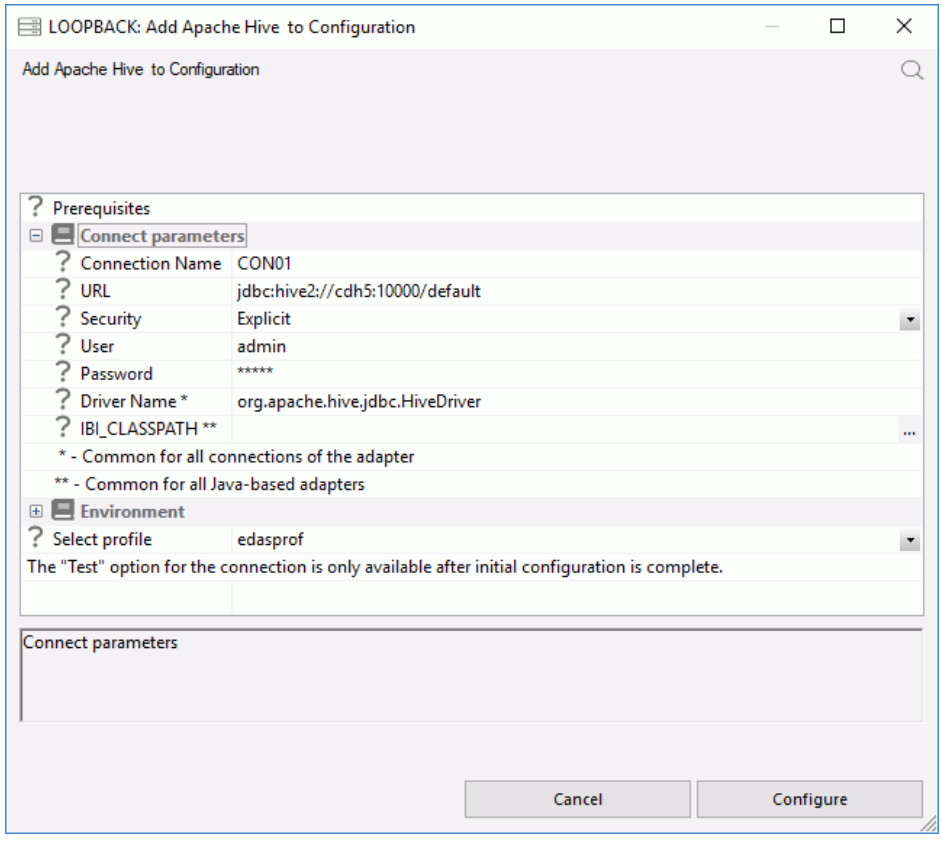
   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click *Apache Hive* and click *Configure*.
5. In the URL box, type the URL used to connect to your Hive server. For more information, see *Hive/Impala Adapter Configuration Settings*.
6. In the Driver Name box, type the driver name from the following table:

Driver	JDBC Driver Name
Apache Hive	`org.apache.hive.jdbc.HiveDriver`
Cloudera/Simba	`com.cloudera.hive.jdbc41.HS2Driver`

7. Select the security type. If you are using Explicit, type your user ID and password.

   The following image shows an example of the configuration settings used:



8. Select *edasprof* from the Select profile drop-down menu to add this connection for all users, or select a user profile.
9. Click *Test*. You should see a list of data sources on your server.
10. Click *Configure*.

Reference: Hive Adapter Configuration Settings

The Adapter for Hadoop/Hive is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Is the URL to the location of the data source.

The URL used depends on what type of server you are connecting to. See the table below for examples. For more details, see the JDBC section in the online documentation for Apache Hive, or the *Cloudera JDBC Driver for Apache Hive* documentation, which is included with the JDBC driver download.

Server	URL
Hiveserver2	`jdbc:hive2://server:10000/default`
Kerberos Hiveserver2 (static)	`jdbc:hive2://server:10000/default; principal=hive/server@REALM.COM`
Kerberos Hiveserver2	`jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM; auth=kerberos;kerberosAuthType=fromSubject`
Cloudera/Simba (no security)	`jdbc:hive2://server:10000;AuthMech=3;transportMode=binary`
Kerberos Cloudera/Simba	`jdbc:hive2://server:10000;AuthMech=1;KrbRealm=REALM.COM; KrbHostFQDN=server.example.com;KrbServiceName=hive`

where:

server

Is the DNS name or IP address of the system where the Hive server is running. If it is on the same system, localhost can be used.

default

Is the name of the default database to connect to.

`10000`

Is the default port number HiveServer2 is listening on if not specified when the Hive server is started.

`REALM.COM`

For a Kerberos enabled Hive server, this Is the name of your realm.

Driver Name

Is the name of the JDBC driver, for example, org.apache.hive.jdbc.HiveDriver or com.cloudera.hive.jdbc41.HS2Driver.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.
- **Trusted.** The user ID is passed from a trusted source.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention). Choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Kerberos

Connections to a Hive server with Kerberos enabled can be run in several ways:

- **Static.** The same Kerberos credential is used for all connections. You must obtain a Kerberos ticket before starting the server. On expiration of the Kerberos ticket, a new one must be obtained and the server must be restarted. Use *Trusted* as the security type.

  This mode is useful for testing, but is not recommended for production deployment.

- **User.** Each user connecting to the server connects to Hive using their own credentials from the Hive Adapter connection in the user profile. The server obtains a Kerberos ticket for the user. Use *Explicit* as the security type.

- **Database.** Users connect to the server using the Kerberos credentials, which are authenticated against a Hive server with Kerberos enabled. The server obtains a Kerberos ticket for the user. Use *Password Passthru* as the security type.

- **Single Sign-on.** Users log into Windows with their Kerberos or Active Directory credentials and Windows obtains a Kerberos ticket. That ticket is used when the user connects to the server and is passed to Hive. Use *Trusted* as the security type.

To setup connections to a Kerberos enabled Hive instance:

- The Reporting Server has to be secured. The server can be configured with security providers PTH, LDAP, DBMS, OPSYS, or Custom, as well as multiple security providers environment,

Kerberos Static Ticket Requirements

In this configuration, all connections to Hive instance will be done with the same Kerberos user ID derived from the Kerberos ticket that is created before the server starts.

1. Create Kerberos ticket using:

   ```
   kinit kerbid01
   ```

where:

kerbid01

Is a Kerberos ID.

2. Verify Kerberos ticket using *klist*. The following message should be returned:

```
Ticket cache: FILE:/tmp/krb5cc_532
Default principal: kerbid01@REALM.COM

Valid starting     Expires            Service principal
04/29/16 16:26:50  04/30/16 02:26:53  krbtgt/REALM.COM@REALM.COM
    renew until 05/06/16 16:26:50
```

3. Before configuring the Hive Adapter connection to a Kerberos-enabled instance, the connection should be tested. Log in to the system running Hive and use Beeline, the native tool, to test it.
4. Start the server in the same Linux session where the Kerberos ticket was created. Log in to the Web Console and click the *Adapters* tab.
5. Right-click *Apache Hive*. Use the following parameters to configure the adapter:

URL

Enter the same URL that you use to connect to the Hive Instance using Beeline. For example:

```
jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM
```

Security

Set to Trusted.

6. In the Select profile drop-down menu, select the *edasprof* server profile.
7. Click *Configure*.
8. Next, configure Java services. Click the *Workspace* tab and expand the *Java Services* folder.
9. Right-click *DEFAULT* and select *Properties*.
10. Expand the *JVM Settings* section. In the JVM options box, add the following:

```
-Djavax.security.auth.useSubjectCredsOnly=false
```

11. Restart Java services.

Once these steps are completed, the adapter can be used to access a Kerberos-enabled Hive instance.

Kerberos User Ticket Requirements

In this configuration, each connected user has a Hive Adapter connection with Kerberos credentials in the user profile.

1. Enable multi-user connection processing for Kerberos by adding the following line to your profile (edasprof.prf):

   ```
   ENGINE SQLHIV SET ENABLE_KERBEROS ON
   ```

2. Kerberos looks for the default realm in /etc/krb5.conf, or on Windows krb5.ini. Make sure that this file contains the information for your Kerberos server, and not the sample file.

   If you are running the server on a Windows system, under the Local System account, specify your realm name and Kerberos Key Distribution Center. To do so:

   a. Expand the *Workspace* folder.

   b. Expand the *Java Services* folder, right-click *DEFAULT*, and click *Properties*.

   c. Expand the JVM settings section and add the following in the JVM Options box:

      ```
      -Djava.security.krb5.realm=REALM.COM
      -Djava.security.krb5.kdc=kdc.realm.com
      ```

      where:

      REALM.COM
      Is the realm name of your organization.

      kdc.realm.com
      Is the Key Distribution Center of your organization.

3. Configure the Hive Adapter Connection in the user profile using the following values:

   URL
   Is the URL to the location of the data source.

Server	URL
Kerberos Hiveserver2 (User)	`jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM; auth=kerberos;kerberosAuthType=fromSubject`

Server	URL
Kerberos Cloudera/Simba	`jdbc:hive2://server:10000;AuthMech=1;KrbRealm=REALM.COM;KrbHostFQDN=server.example.com;KrbServiceName=hive`

Security

Set to Explicit.

User and Password

Enter your Kerberos user ID and password. The server will use those credentials to create a Kerberos ticket and connect to a Kerberos-enabled Hive instance.

Note: The user ID that you use to connect to the server does not have to be the same as the Kerberos ID you use to connect to a Kerberos-enabled Hive instance.

Select Profile

Select your profile or enter a new profile name consisting of the security provider, an underscore and the user ID. For example, *ldap01_pgmxxx*.

4. Click *Configure*.

Kerberos Password Passthru Requirements

This procedure will show you how to create a connection to a Kerberos enabled Hadoop Cluster using the Adapter for Apache Hive with security Password Passthru.

1. Configure the connection to Hive using the following values:

   URL

   Is the URL to the location of the data source.

   ```
   jdbc:hive2://server1:10000/default;principal=hive/server1@REALM.COM;
   auth=kerberos;kerberosAuthType=fromSubject
   ```

   where:

   server1

   Is the name of a node on your Hadoop cluster where a Hive2 server is running.

   Security

   Set to Password Passthru.

   Select Profile

   Select the server profile, *edasprof*.

   Driver Name

   Is the name of the JDBC driver, for example, org.apache.hive.jdbc.HiveDriver.

   IBI_CLASSPATH

   Defines the additional Java Class directories or full-path jar names which will be available for Java Services (if not included in your system CLASSPATH).

   ```
   /path/to/hive-jdbc-<version>standalone.jar
   ```

2. Click *Configure*.

   You also need to configure Hive as a DBMS Security Provider.

3. From the Web Console, click *Access Control*.
4. Under Security Providers, right-click *DBMS* and click *New*.

   The DBMS Security Provider Configuration page opens.

5. Enter the following values:

   DBMS Provider

   Enter the provider, as desired. For example, hive.

   Security DBMS

   Select *SQLHIV - Apache Hive*.

   security_connection

   The connection name you specified, for example, *server*.

6. Click *Save*.

   The DBMS Security Provider Configuration page opens.

7. Select the line *DBMS - hive* , where *hive* is the name you used. .
8. From the Status drop-down menu, select *Primary* or *Secondary*, as desired.

Kerberos Single Sign-On Requirements

The following sections will show you how to configure a DataMigrator or WebFOCUS Reporting Server for access to Hadoop through Hive with Kerberos enabled Hadoop Cluster using the Adapter for Apache Hive with single sign-on from the desktop to the browser using Hive.

1. Configure the connection to Hive using the following values:

   URL

   Is the URL to the location of the data source.

   ```
   jdbc:hive2://server1:10000/default;principal=hive/server1@IBI.COM;
   auth=kerberos;kerberosAuthType=fromSubject
   ```

   where:

   server1

   Is the name of a node on your Hadoop cluster where a Hive2 server is running.

   Security

   Set to Trusted.

   Select Profile

   Select the server profile, *edasprof*.

   Driver Name

   Is the name of the JDBC driver, for example, org.apache.hive.jdbc.HiveDriver.

   IBI_CLASSPATH

   Defines the additional Java Class directories or full-path jar names which will be available for Java Services (if not included in your system CLASSPATH).

   ```
   /path/to/hive-jdbc-<version>standalone.jar
   ```

2. You also need to configure the server for inbound Kerberos.
3. Click *Configure*.

Configuring the DataMigrator or Reporting Server for Inbound Kerberos

A server started with security provider OPSYS can be configured for Kerberos connections.

To implement the single sign on Kerberos security:

1. On the Access Control page, right-click the OPSYS provider, and select *Properties* from the context menu.

   The OPSYS Security Configuration page opens.

2. In the krb5_srv_principal * field, enter your server principal used for Kerberos security.
3. Click *Save*.

   The edaserve.cfg file is updated with this attribute.
4. On the Workspace page, expand the Special Services and Listeners folder, right-click *TCP/HTTP*, and select *Properties of TCP*.
5. Check SECURITY=KERBEROS.
6. Click *Save and Restart Listener*.

   The odin.cfg file is updated with this attribute.

When the server is started, a user can connect to the Web Console from Internet Explorer without a prompt for user ID and password. The *Login Info* shows connection type *Kerberos*. The connection is done using the Kerberos ticket from the browser. The connected user ID is derived from this ticket.

Connection to the server requires that there is a local OPSYS user ID with the same name as the Kerberos user ID on the operating system running the server. This user ID is used for tscom3 process impersonation.

If a user signs off from the Kerberos connection, the user can make explicit connections with the local Unix user ID and password. Connection with another Kerberos user ID as an explicit connection will not work.

Configuring Java Authentication and Authorization Services

Once you configure a DataMigrator or WebFOCUS Reporting Server for access to Hadoop through Hive, you must also configure Java to use the HTTP service principal.

1. Using the name of the HTTP service principal for your server that you specified when configuring the DataMigrator or WebFOCUS Reporting Server for inbound Kerberos, store the credentials for this principal in a keytab. Enter the following line:

   ```
   $ klist -k /etc/krb5.keytab
   ```

   Confirm the credentials are stored correctly, as follows:

   ```
   Keytab name: FILE:/etc/krb5.keytab
   KVNO Principal
   ---- --------------------------------------
       1 HTTP/server.example.com@REALM.COM
   ```

2. Create a jaas.conf file in the location of your choice, using your preferred text editor, for example, /ibi/srv82/wfs/etc/jaas.conf. The example code also shows sample values for the keyTab and principal parameters.

```
jconnection {
 com.sun.security.auth.module.Krb5LoginModule required
 debug=false doNotPrompt=true useKeyTab=true
 keyTab="/etc/krb5.keytab"
 storeKey=true isInitiator=false
 principal="HTTP/server.example.com@REALM.COM";;
};
com.sun.security.jgss.accept {
 com.sun.security.auth.module.Krb5LoginModule required debug=false
 doNotPrompt=true useKeyTab=true
 keyTab="/etc/krb5.keytab"
 storeKey=true isInitiator=false
 principal="HTTP/server.example.com@REALM.COM";;
};
```

3. From the Web Console, click the *Workspace* folder.
4. Expand the *Java Services* folder, right-click *DEFAULT*, and click *Properties*. The Java Services Configuration window opens.
5. Expand the JVM section. In the JVM_Options box, enter the location where you saved the jaas.conf file. For example:

   ```
   -Djava.security.auth.login.config=/ibi/srv82/wfs/etc/jaas.conf
   ```

6. Click *Save and Restart Java Services*.

Troubleshooting

Here are some of the errors you may see when attempting to connect to a Hadoop cluster. These error messages will be prefixed by FOC1500.

Java listener may be down

```
ERROR: ncjInit failed.  Java listener may be down - see edaprint.log.
```

This is a Java specific issue. Confirm that your Java version meets your system requirements for bit size (32 bit vs 64 bit), and that the value for JAVA_HOME is pointing to the correct Java version.

No suitable driver found for jdbc: ...

```
(-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: No suitable driver found for jdbc:hive1://server:10000/default
```

The name of the JDBC driver in the URL is incorrect. For example, in the above URL, the driver is *hive1*.

ClassNotFoundException

```
(-1) [00000] JDBFOC>> connectx(): java.lang.ClassNotFoundException:
org.apache.hive.jdbc.HiveDriver
```

One of the jar files that comprises the Hive JDBC driver is not found in the CLASSPATH, or the driver name is incorrect. In the above example, the driver name is org.apache.hive.jdbc.HiveDriver.

Required field 'client_protocol' is unset!

```
(-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: Could not establish connection to
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: Required field
'client_protocol' is unset! Struct:TOpenSessionReq(client_protocol:null,
configuration:{use:database=default})
```

This is due to a Java version mismatch. The version of Java on the client is newer than the one on the server. To resolve this error, update Java on the system where you are running our server.

Could not open client transport with JDBC Uri:

```
-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: Could not open client transport with JDBC Uri:
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: ...
```

This is a generic error, and could be due to any kind of error in the URL or configuration. For more details, read the rest of the message.

Unsupported mechanism type PLAIN

```
 (-1) [00000] JDBFOC>> makeConnection():  conn is NULLjava.sql.
SQLException: Could not open client transport with JDBC Uri:
jdbc:hive2://server:10000/default: Peer indicated failure: Unsupported
mechanism type PLAIN
```

The cluster has Kerberos enabled and a Kerberos principal to authenticate against is not specified. To resolve this error, add the following to the end of the URL using your cluster and REALM name:

```
;principal=hive/server@REALM.COM
```

UnknownHostException: *server*

```
(-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: Could not open client transport with JDBC Uri:
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: java.net.
UnknownHostException: name
```

The server you specified could not be reached. Either the system is down or the name is invalid.

Could not open client transport with JDBC Uri:... Connection refused

```
(-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: Could not open client transport with JDBC Uri:
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: java.net.
ConnectException: Connection refused: connect
```

The hostname could be reached, but there is no Hive Thrift server running at the hostname and port number you specified

Client not found in Kerberos database

```
(-1) [00000] JDBFOC>> makeConnection(): javax.security.auth.login.
LoginException: Client not found in Kerberos database (6)
```

The user ID (User Principal Name) specified is not a valid Kerberos user ID.

Pre-authentication information was invalid

```
-1) [00000] JDBFOC>> makeConnection():
javax.security.auth.login.LoginException: Pre-authentication
information was invalid (24)
```

The user ID (User Principal Name) specified was found, but the password is missing or invalid.

GSS initiate failed

```
(-1) [00000] JDBFOC>> makeConnection(): conn is NULLjava.sql.
SQLException: Could not open client transport with JDBC Uri:
jdbc:hive2://server:10000/default;principal=hive/server@domain.
COM; GSS initiate failed
Caused by: org.apache.thrift.transport.TTransportException:
```

Kerberos was unable to authenticate against the specified Service Principal Name.

This occurs if you are using static credentials that were obtained by kinit before the server starts, and did not specify the option to allow that. To resolve this issue, from the Web Console:

1. Click *Workspace* in the side bar.
2. Expand the *Java Services* folder.
3. Right-click *DEFAULT*.
4. Click *Properties*.
5. Expand the *JVM Settings* section.
6. Enter the following in the JVM_OPTIONS box:

   ```
   -Djava.security.auth.useSubjectCredsOnly=false
   ```

This also occurs if you are using subject credentials with explicit or password pass through security, but did not specify that you are doing so. Add the following to the end of the URL:

```
;auth=kerberos;kerberosAuthType=fromSubject
```

Could not create secure connection to ... Failed to open client transport

```
(0) [ 08S0] Could not create secure connection to
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: Failed to open client
transportjava.sql.SQLException: Could not create secure connection to
jdbc:hive2://server:10000/default;principal=hive/server@REALM.
COM;auth=kerberos;kerberosAuthType=fromSubject: Failed to open client
transport
```

The client was not able to use Kerberos to connect. You did not enable Kerberos and are using subject credentials. To resolve this issue, add the following to the server profile:

```
ENGINE SQLHIV SET ENABLE_KERBEROS ON
```

Cannot locate default realm

```
(-1) [00000] JDBFOC>> makeConnection(): javax.security.auth.login.
 LoginException: KrbException: Cannot locate default realm
```

Kerberos looks for the default realm in /etc/krb5.conf, or on Windows krb5.ini, and it either cannot find or read the file or the default realm is not specified.

For a server running as a service on a Windows machine, you must explicitly specify the realm for the organization and the KDC. Review the file to make sure that the default realm is specified and correct. To resolve this issue, from the Web Console:

1. Click *Workspace* in the side bar.
2. Expand the *Java Services* folder.
3. Right-click *DEFAULT*.
4. Click *Properties*.
5. Expand the *JVM Settings* section.
6. Using the name of your realm and Key Distribution Center (KDC), enter the following in the JVM_OPTIONS box:

   ```
   -Djava.security.krb5.realm=REALM.COM
   -Djava.security.krb5.kdc=kdc.domain.com
   ```

Click *Save and Restart Java Services*.

Creating Synonyms With Apache Hive

Synonyms define unique names, or aliases, for each Hive table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Hive table.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.

   The Applications page opens.

2. On the Configured list, right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.

4. After entering the parameter values, click the *Add* button.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Using Direct Pass-through With Apache Hive

Direct Pass-through commands, such as SHOW TABLES and DESCRIBE tablename, do not display any results.

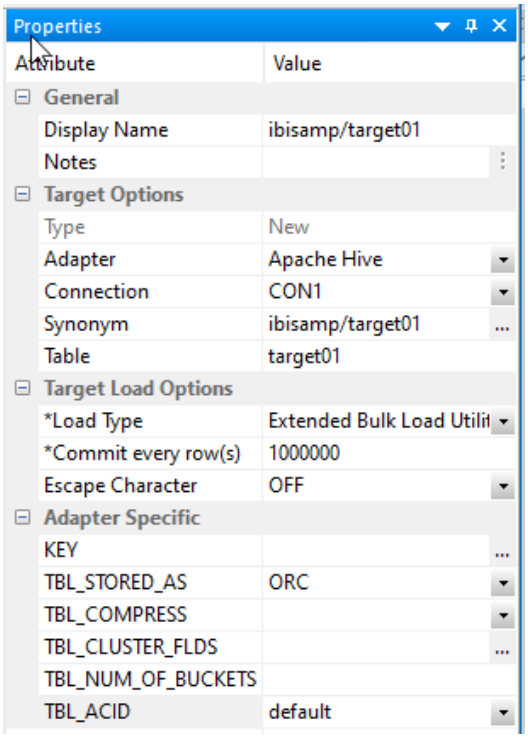
This can be avoided by adding a comment:

```
ENGINE SQLHIV
/*QUERY*/ SHOW TABLES ;
END
```

Loading Data Using DataMigrator

DataMigrator can be used to load data from any accessible data source into Hadoop and create metadata in Hive. Currently, the only load type supported is Extended Bulk Load. The exception are files stored as ORC (Optimized Row Columnar) format, for which Insert/Update can be used.

The table should be stored as TEXTFILE (default), ORC, or Parquet, as shown in the following image.



For a new ORC table, you can use the TBL_ACID property to specify whether transactions are supported. The default is the setting specified in Hive. You can select Yes, if you want the new Hive table to support transactions, or No, if you do not want it to support new transactions.

You can set the Escape Character property to ON to properly process data with non-printable characters.

For more information, see the *DataMigrator User's Guide*.

Chapter 10 Using the Adapter for Apache Phoenix to Access HBase

Apache Phoenix is a query engine for Apache HBase and MapR-DB.

In this chapter:

Preparing the Apache Phoenix Environment

The following components are needed to use the adapter for Apache Phoenix:

- **Java.** To use this Java-based adapter, you must have Java, Version 1.8 or later, installed. Java can be downloaded from *http://www.java.com*.

  The location of the Java must be specified in an environment variable.

  If you are using Linux, add a line to your profile with the location where Java is installed. For example:

  ```
  export JAVA_HOME=/usr/lib/jvm/jre-1.8.0
  ```

  If you have JDK installed:

  ```
  export JAVA_HOME=/usr/lib/jvm/jdk-1.8.0
  ```

  If you are using Windows, right-click *Computer* and select *Properties*. Then click *Advanced System Settings* and click *Environment Variables*. Add the locations to your PATH variable. For example:

  ```
  C:\Program Files\Java\jdk-8\bin\server;C:\Program Files\Java\jdk-8\bin;
  ```

- **JDBC Driver.** The JDBC driver consists of a jar file distributed with Apache Phoenix. If you are installing the server on the same system where Apache Phoenix is installed, you can point to the jar file as described in the next section. If you are installing the server on some other system, copy the file to a location of your choice.

Procedure: How to Configure the Java CLASSPATH

The location of the Apache Phoenix JDBC Driver must be specified to the server. If you are running the server on the same system as a Drillbit, you can specify its location. If you are running the server on another system, copy the files listed below to some location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, select *Workspace*

   or

   From the Data Management Console, expand the *Workspace* folder.

2. Expand the *Java Services* folder. Right-click *DEFAULT* and click *Properties*.

   The Java Services Configuration page opens.

3. Click on the chevrons to expand Class path.

   In the IBI_CLASSPATH box, enter the full location of the jar file. For example:

   ```
   /usr/lib/phoenix/phoenix-client.jar
   ```

   Note:

   - The file names must be entered one per line.

     If you are installing the adapter on a different system than where you have Apache Phoenix installed, copy the jar file to a location on that system.

   - For a server running on Windows, use Windows syntax for directory names. For example:

     ```
     C:\phoenix\phoenix-client.jar
     ```

   - If your Hadoop cluster is Kerberos enabled, add the name of the directory containing the configuration files hbase-site.xml and core-site.xml. By default, if the server is installed on the same system where Hadoop or HBase were installed, these files are located in the /etc/hbase/conf directory. If the server is installed on a different system, use the name of the directory where you copied the configuration files. For example:

     - **For a Linux system:**

       ```
       /etc/hbase/conf
       ```

- **For a Windows system:**

  ```
  c:\phoenix
  ```

4. Scroll down and click the *Save and Restart Java Services* button.

Configuring the Adapter for Apache Phoenix

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Apache Phoenix Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click *Apache Phoenix* and click *Configure*.
5. In the URL box, enter the URL used to connect to your Drillbit. For more information, see *Apache Phoenix URL Configuration Settings* on page 312.
6. In the Driver Name box, enter the following:

   ```
   org.apache.phoenix.jdbc.PhoenixDriver
   ```

7. For Security, select *Trusted*.

   Note: Explicit should not be used because Phoenix ignores any user ID that is entered; it connects with the user ID that was used to start the server. Individual user credentials can only be used with a secured (Kerberos enabled) server and are specified in the URL.

8. Click *Configure*.

Reference: Apache Phoenix URL Configuration Settings

The Adapter for Apache Phoenix is under the SQL group folder.

The URL configuration for the Apache Phoenix adapter is:

```
jdbc:phoenix:quorum:[port:[/directory[:principal[:keytab]]]]
```

where:

quorum

Is a comma separated list of ZooKeeper servers.

port

Is the port number for ZooKeeper. The default value is 2181. On a MapR cluster, the default value is 5181.

directory

Is the name of the Phoenix directory within ZooKeeper.

For a server that does not have Kerberos enabled, the default is */hbase-unsecure* .

For a Kerberos enabled server, the default is */hbase-secure*.

Note: The directory names listed above must be entered exactly as written.

principal

The Kerberos user principal. For example:

user@REALM

keytab

The Kerberos keytab containing the specified user. For example:

```
/home/user/user.keytab
```

The following is an example of an unsecured server with one zookeeper node:

```
jdbc:phoenix:clu0:2181:/hbase-unsecure
```

The following is an example for a secured server with three zookeeper nodes:

```
jdbc:phoenix:clu1,clu2,clu3:2181:/user@REALM.COM:
/user/home/user.keytab
```

Troubleshooting

If the server is unable to configure the connection, a dialog box opens with an error message. The message typically begins with the following:

```
(FOC1400) SQLCODE IS -1 (HEX: FFFFFFFF) XOPEN: nnnn
```

where:

nnnn

Is the message number returned.

Some of the more common errors are:

```
(FOC1500) : (-1) [00000] JDBFOC>> connectx():
(FOC1500) : java.lang.UnsupportedClassVersionError:
org/apache/drill/jdbc/Driver :
(FOC1500) : Unsupported major.minor version 51.0
(FOC1479) ERROR CONNECTING TO SQL DATABASE
```

This indicates that your Java version is less than 1.8, which is required.

Creating Synonyms With Apache Phoenix

Synonyms define unique names, or aliases, for each Phoenix table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Phoenix table.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter and a connection.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

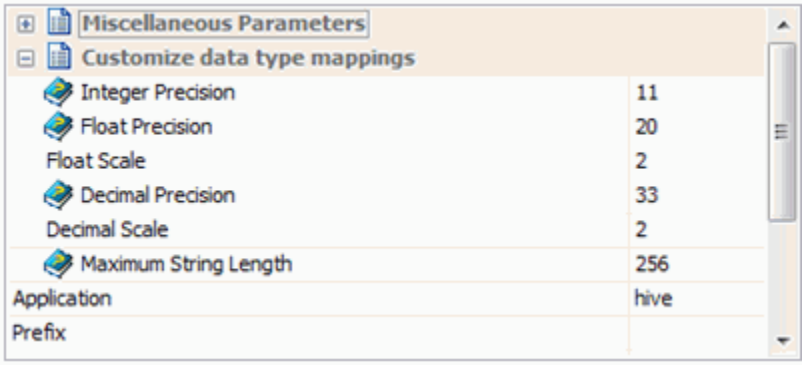
   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.

- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.
5. Optionally, expand the *Customize data type mappings* section and enter a value for Maximum String Length or numeric precision, as shown in the following image.



6. Select the check box for the objects that you want to create synonyms for. If you want to change the name of the synonym from the default name, click the name and edit it as needed.
7. Click *Create Synonym*.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Chapter 11

Using the Adapter for Apache Spark

The Adapter for Spark provides for analysis of both structured and complex data. Apache Spark is a fast and general engine for large-scale data processing.

In this chapter:

Introducing the Adapter for Apache Spark

Apache Spark is a fast and general engine for large-scale data processing

Apache Spark can run on Hadoop or in a standalone cluster mode. Data can be stored in HDFS, the local file system, or on Cloud.

The Adapter for Apache Spark uses JDBC to connect to the Spark SQL Thrift Server.

The Adapter for Apache Spark is JDBC based. The DataMigrator or WebFOCUS server can be run on any platform (including Windows) that connects to the server where Hive is running.

Preparing the Apache Spark Environment

The following components are needed to use the adapter for Hadoop/Hive:

- **Java.** To use this JDBC-based adapter, you must have Java installed. Hadoop requires Version 1.7 or later. Java can be downloaded from *http://www.java.com*.

  The location of Java must be specified in an environment variable.

  If you are using Linux, add a line to your profile with the location where Java is installed. For example:

  ```
  export JAVA_HOME=/usr/lib/jvm/jre-1.7.0
  ```

If you have JDK installed:

```
export JAVA_HOME=/usr/lib/jvm/jdk-1.7.0
```

If you are using Windows, right-click *Computer* and click *Properties*. Then click *Advanced System Settings* and click *Environment Variables*. Add the locations to your PATH variable. For example:

```
C:\Program Files\Java\jdk7\bin\server;C:\Program Files\Java\jdk7\bin;
```

- **JDBC Drivers.** The Spark JDBC driver requires two jar files, which are included with Apache Spark. If you are installing the server on the same system where Spark is installed, you can point to the jar files as described in the next section. If you are installing the server on some other system, copy those files to a location of your choice.

Procedure: How to Configure the Java CLASSPATH

The location of the Apache Spark jar files must be specified to the server. If you are running the server on the same system as the Hadoop and Hive server, you can specify their location. If you are running the server on another system, copy the files listed below to some location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, select *Workspace*

   or

   From the Data Management Console, expand the *Workspace folder*.

2. Expand the *Java Services* folder. Right-click *DEFAULT* and click *Properties*.

   The Java Services Configuration page opens.

3. Expand *Class path*.

   In the IBI_CLASSPATH box, enter the full location of the Spark files shown below. The file names must be entered one per line.

   If you are installing the adapter on a different system than where Hadoop and Hive are installed, copy the jar files to a location on that system.

   Enter the location on your system that matches your installation.

   ```
   hive-jdbc-<version>-standalone.jar
   hadoop-common.jar
   ```

Configuring the Adapter for Apache Spark

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Adapter for Apache Spark

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click *Apache Spark SQL* and click *Configure*.

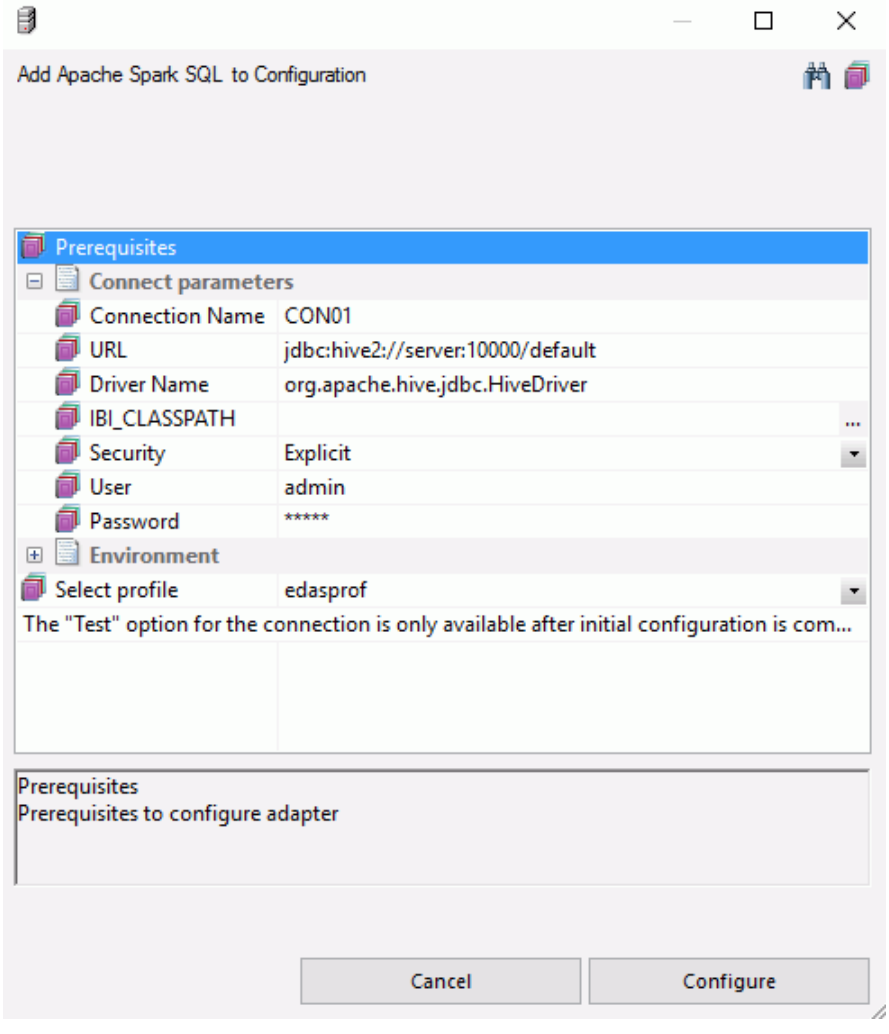
5. In the URL box, type the URL used to connect to your Hive server. For more information, see *Hive/Impala Adapter Configuration Settings*.

6. In the Driver Name box, type the driver name from the following table:

Driver	JDBC Driver Name
Apache Spark	`org.apache.hive.jdbc.HiveDriver`

7. Select the security type. If you are using Explicit, type your user ID and password.

The following image shows an example of the configuration settings used:



8. Select *edasprof* from the Select profile drop-down menu to add this connection for all users, or select a user profile.
9. Click *Configure*.
10. Click *Test*. You should see a list of data sources on your server.

Reference: Adapter for Apache Spark Configuration Settings

The Adapter for Hadoop/Hive is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Is the URL to the location of the data source.

The URL used depends on what type of server you are connecting to. See the table below for examples.

Server	URL
Hiveserver2	`jdbc:hive2://server:10000/default`
Kerberos Hiveserver2 (static)	`jdbc:hive2://server:10000/default; principal=hive/server@REALM.COM`
Kerberos Hiveserver2 (user)	`jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM; auth=kerberos;kerberosAuthType=fromSubject`

where:

server

Is the DNS name or IP address of the system where the Hive server is running. If it is on the same system, localhost can be used.

default

Is the name of the default database to connect to.

10000

Is the default port number Spark Thrift Server is listening on if not specified when the Hive server is started.

REALM.COM

For a Kerberos enabled Hive server, this Is the name of your realm.

Driver Name

Is the name of the JDBC driver, org.apache.hive.jdbc.HiveDriver.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. This value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions when setting values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar). When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Kerberos

Connections to a Hive server with Kerberos enabled can be run in one of two ways:

- **Static.** The same Kerberos credential is used for all connections. You must obtain a Kerberos ticket before starting the server. On expiration of the Kerberos ticket, a new one must be obtained and the server must be restarted.

  This mode is useful for testing, but is not recommended for production deployment.

- **User.** Each user connecting to the server connects to Hive using their own credentials from the Adapter for Apache Spark connection in the user profile. The server obtains a Kerberos ticket for the user.

To setup connections to a Kerberos enabled Spark Thrift Server instance if each user has their own connection, the Reporting Server has to be secured. The server can be configured with security providers PTH, LDAP, DBMS, OPSYS, or Custom, as well as multiple security provider environments.

Kerberos Static Ticket Requirements

In this configuration, all connections to the Spark Thrift Server instance will be done with the same Kerberos user ID derived from the Kerberos ticket that is created before the server starts.

1. Create Kerberos ticket using:

   ```
   kinit kerbid01
   ```

   where:

   kerbid01

   Is a Kerberos ID.

2. Verify Kerberos ticket using *klist*. The following message should be returned:

   ```
   Ticket cache: FILE:/tmp/krb5cc_532
   Default principal: kerbid01@REALM.COM

   Valid starting     Expires            Service principal
   04/29/16 16:26:50  04/30/16 02:26:53  krbtgt/REALM.COM@REALM.COM
       renew until 05/06/16 16:26:50
   ```

3. Before configuring the Spark Thrift Server connection to a Kerberos-enabled instance, the connection should be tested. Use Beeline, the native tool, to test it.

4. Start the server in the same Linux session where the Kerberos ticket was created. Log in to the Web Console and click the *Adapters* tab.

5. Right-click *Apache Spark SQL*. Use the following parameters to configure the adapter:

   URL

   Enter the same URL that you used to connect to the Hive Instance using Beeline.

   ```
   jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM
   ```

   Security

   Set to *Trusted*.

6. In the Select profile drop-down menu, select the *edasprof* server profile.
7. Click *Configure*.
8. Next, configure Java services. Click the *Workspace* tab and expand the *Java Services* folder.
9. Right-click *DEFAULT* and click *Properties*.
10. Expand the *JVM Settings* section. In the JVM options box, add the following:

    ```
    -Djavax.security.auth.useSubjectCredsOnly=false
    ```

11. Restart Java services.

Once these steps are completed, the adapter can be used to access a Kerberos-enabled Spark Thrift Server instance.

Kerberos User Ticket Requirements

In this configuration, each connected user has a Hive Adapter connection with Kerberos credentials in the user profile.

1. Enable multi-user connection processing for Kerberos by adding the following line to your profile (edasprof.prf):

   ```
   ENGINE SQLSPK SET ENABLE_KERBEROS ON
   ```

2. Configure the Hive Adapter Connection in the user profile using the following values:

URL

Is the URL to the location of the data source.

Server	URL
Kerberos Hiveserver2 (User)	`jdbc:hive2://server:10000/default;principal=hive/server@REALM.COM; auth=kerberos;kerberosAuthType=fromSubject`

Security

Set to Explicit.

User and Password

Enter your Kerberos user ID and password. The server will use those credentials to create a Kerberos ticket and connect to a Kerberos-enabled Spark Thrift Server instance.

Note: The user ID that you use to connect to the server does not have to be the same as the Kerberos ID you use to connect to a Kerberos-enabled Spark Thrift Server instance.

Select Profile

Select your profile or enter a new profile name consisting of the security provider, an underscore and the user ID. For example, *ldap01_pgmxxx*.

3. Click *Configure*.

Troubleshooting

If the server is unable to configure the connection, an error message is displayed. An example of the first line in the error message is shown below, where *nnnn* is the message number returned.

```
(FOC1400) SQLCODE IS -1 (HEX: FFFFFFFF) XOPEN: nnnn
```

Some common errors messages are:

```
[00000] JDBFOC>> connectx(): java.lang.UnsupportedClassVersionErr : or: org/
apache/hive/jdbc/HiveDriver : Unsupported major.minor version 51.0
```

The adapter requires Java 1.7 or later and your JAVA_HOME points to Java 1.6.

```
(FOC1500)  :  ERROR: ncjInit failed. failed to connect to java server: JSS
(FOC1500)  :   . JSCOM3 listener may be down - see edaprint.log for details
```

The server could not find Java. To see where it was looking, review the edaprint.log and set JAVA_HOME to the actual location. Finally, stop and restart your server.

```

```

The Spark Thrift server is not listening on the specified port. Start the server if it is not running, and check that the port number is correct.

Creating Synonyms With Apache Spark

Synonyms define unique names, or aliases, for each Hive table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Hive table.

Procedure: How to Create a Synonym With Apache Spark

To create a synonym, you must have previously configured the adapter and a connection.

1. From the Web Console *Applications* page, click *Get Data*.

2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Using Direct Pass-through With Apache Spark

Direct Pass-through commands, such as SHOW TABLES and DESCRIBE tablename, do not display any results.

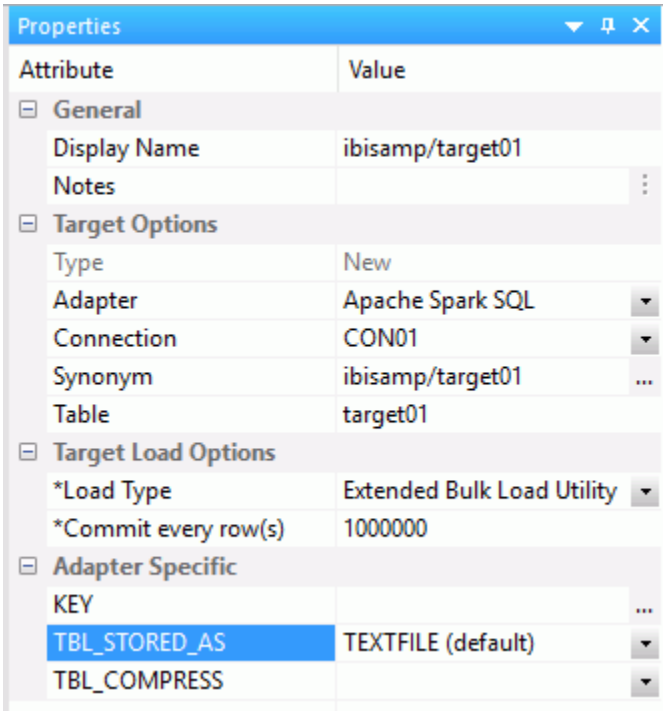
This can be avoided by adding a comment:

```
ENGINE SQLSPK
/*QUERY*/ SHOW TABLES ;
END
```

Loading Data into Apache Spark Using DataMigrator

DataMigrator can be used to load data from any accessible data source into Hadoop and create metadata in Hive. Currently, the only load type supported is Extended Bulk Load. The exception are files stored as ORC (Optimized Row Columnar) format, for which Insert/Update can be used.

The table should be stored as TEXTFILE (default), ORC, or Parquet, as shown in the following image.



For more information, see the *DataMigrator User's Guide*.

Chapter 12

Using the Adapter for Axiom EPM

The Adapter for Axiom EPM provides data access for reporting from the following Axiom EPM Table Types: Data, Reference, and DocumentBasedReferenced. The adapter fully enforces Axiom EPM security.

The adapter provides three types of services:

- Authentication services.
- Axiom EPM data source connection management services.
- Metadata administration and data access security services.

In this chapter:

Preparing the Axiom EPM Environment

Prior to configuring the Adapter for Axiom EPM, you must ensure that minimal software requirements have been met. In addition, you must define an Axiom EPM Access ID to enforce Axiom EPM security. Administrators must also review available connection options before beginning the initial configuration.

Software Requirements

The following software is required on the server to support the Adapter for Axiom EPM:

- An appropriate RDBMS connectivity product on the computer where you will install the Adapter for Axiom EPM server. This is to provide access to an Axiom EPM data source server for operational data access.

Note: For information about Axiom EPM with versions of software other than those listed in this topic, contact your Information Builders representative.

Setting Up the Axiom EPM Access ID

The Adapter for Axiom EPM initially authenticates with Axiom EPM using an Axiom EPM Administrator user ID and password. If successful, the adapter attaches to the RDBMS using an access ID of your choice. Typically, this access ID is an RDBMS ID dedicated to the adapter. If required, this access ID can also be an Axiom Administrator ID.

In addition, the access ID must have read access to any Axiom EPM Tables that you wish to report against.

Note: The Axiom Adapter is not supported when the Server is running in Pooled deployment mode.

Configuring the Adapter for Axiom EPM

Before configuring the adapter for Axiom EPM, you must first register the Axiom EPM application (AXIOMCAT) in the catalog path, add the underlying SQL adapter, and add the REST adapter for administration and security information retrieval.

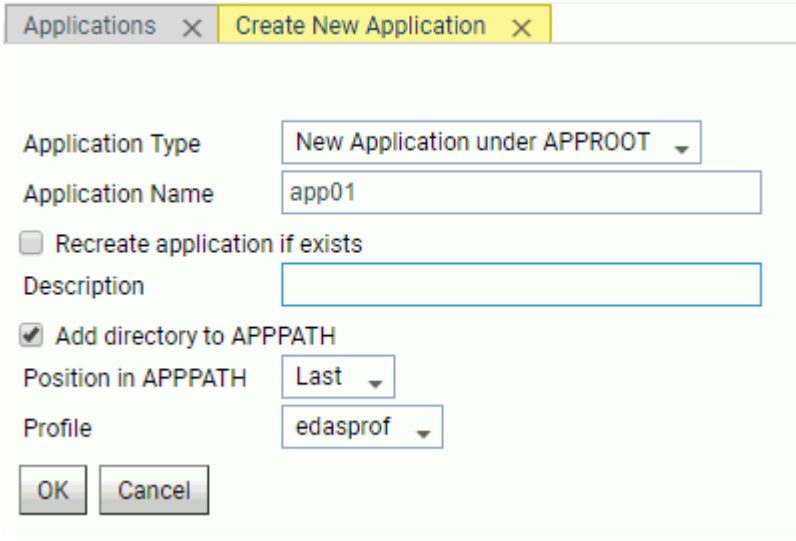
Creating the AXIOMCAT Application

Before you can configure the Axiom EPM adapter, the AXIOMCAT application must be created and added to the application path of the server. This can be done through the Web Console.

Procedure: How to Create the AXIOMCAT Application

1. From the Web Console menu bar, select *Applications*.
2. Right-click the *Application Directories* folder and select *New*, *Application Directory*.

The Create New Application window opens, as shown in the following image.



3. Change the Application Name to *axiomcat*. Make sure it is all in lowercase.
4. Click *OK*.

Adding the SQL Database Adapter

The Adapter for Axiom EPM is an enhanced version of the underlying data source adapter. The adapter must be added into the server configuration.

When you add an SQL adapter, there is no need to provide configuration parameters. Instead, these configuration parameters are supplied later when configuring connections to Axiom EPM data sources.

Example: Adding an Adapter

The Web Console provides graphical point and click tools to add and test the adapter.

1. From Web Console sidebar, click *Connect to Data*.
2. Expand the *Available* folder, if it is not already expanded.
3. Expand the *SQL* group folder and a *MS SQL Server* or *Oracle* folder.
4. Right-click a version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. For Oracle, no configuration parameters are required. For MS SQL Server, supply any value for the mandatory *Server* parameter. It does not have to be a valid MS SQL server name. *Myserver* is adequate.
6. Click *Configure*.

   The adapter is added to your server configuration.

Adding the REST Adapter and Connection

The Adapter for Axiom EPM uses REST API calls to obtain metadata and security information from the Axiom EPM environment. To do this, a connection to Axiom needs to be configured.

Procedure: How to Configure the REST Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

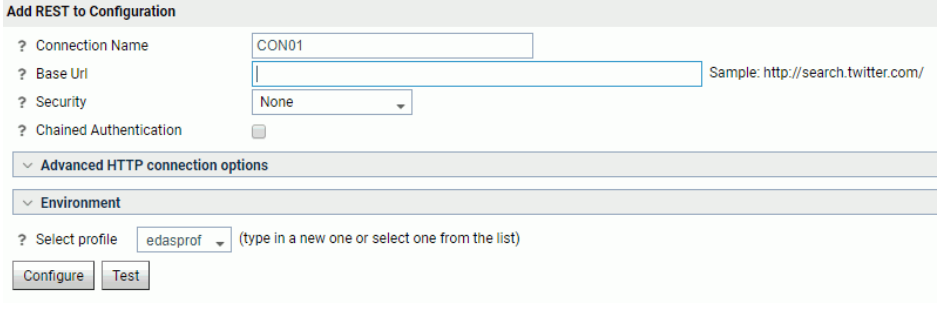
1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click *REST*, and select *Configure*.

   The Add REST to configuration pane opens, as shown in the following image.



5. Provide the following information:

   Connection Name

   Enter the following value exactly as shown:

   AxiomToken

   Service Description

   None

   Base URL

   Enter the URL of the machine where the Axiom software is installed in the following format:

   `http://machine.name.com`

   Security

   Select *Password Passthru* from the drop-down menu.

6. Select the *Chained Authentication* check box.

   Provide the following information:

   Additional Chained Authentication Information

   Authentication synonym

   Enter the following value in lowercase:

   `axgettok`

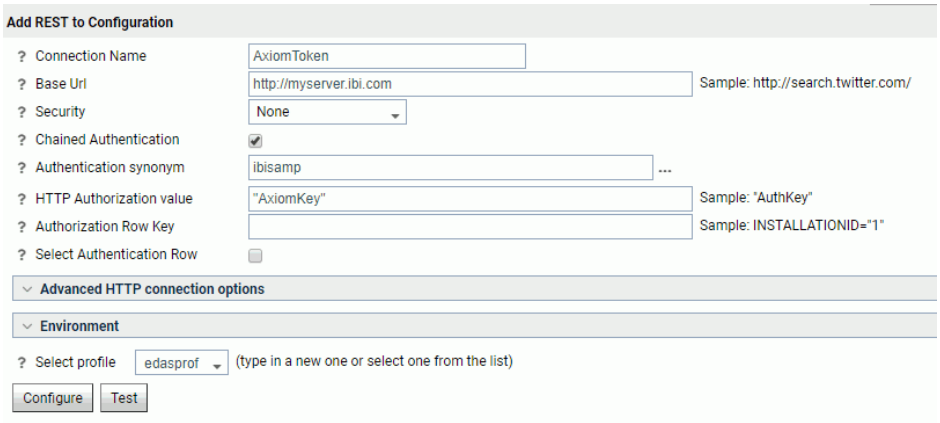
   HTTP Authorization value

   Enter the following (including double quotation marks):

   `"AxiomKey"`

7. Make sure the *Select profile* drop-down menu points to *edasprof*.

The pane should now look like the following image, except for the Base URL, which will reflect an installation value.



8. Click *Configure*.

Adding the First Connection to Axiom EPM

Although multiple Axiom EPM connections can be created, the first connection requires slightly different management steps. The reason for this is that before any connections to Axiom EPM data sources can occur, a base layer of application metadata is created and configured. This occurs transparently for the Administrator, but is a slightly different connection management process than when adding additional connections.

To create the first connection:

- ❑ Select an existing Axiom Administrator ID.

  The Administrator ID is the value that is used as a metadata access key. To access the Web Console, the administrator must know this ID. Users outside of the Web Console do not have metadata access without first logging in to Axiom EPM through this integration.

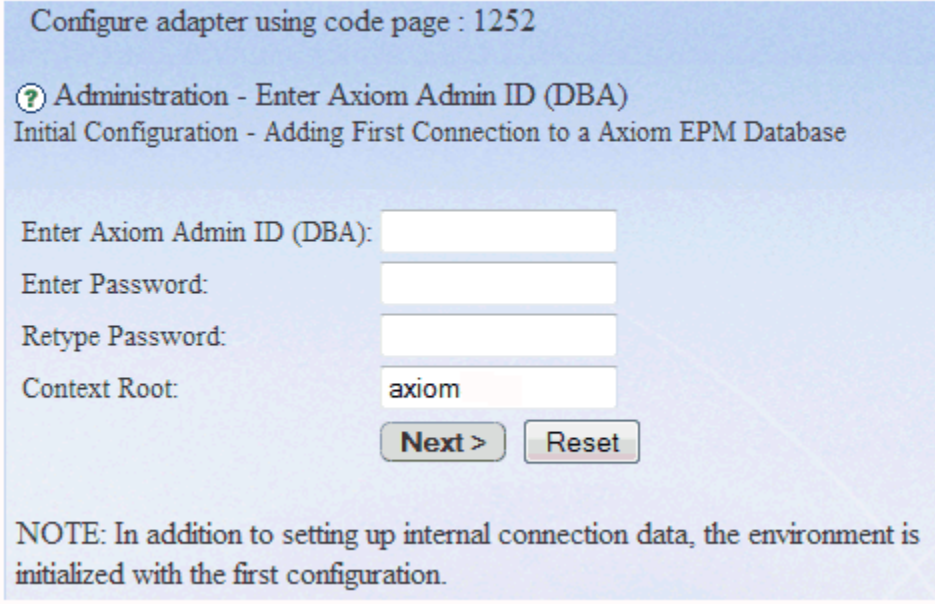
- ❑ Add an Axiom EPM Connection.

Procedure: How to Add the First Axiom EPM Connection

1. Open the Web Console.
2. From Web Console sidebar, click *Connect to Data*.
3. Expand the *Available* folder, if it is not already expanded.
4. Expand the *ERP* group folder.

5. Right-click *Axiom EPM*, and select *Configure*.
6. Click *Configure*.
7. Click *Next*.

   The Administration - Enter Axiom Admin ID (DBA) opens, as shown in the following image.



8. In the *Enter Axiom Admin ID (DBA)* field, enter the administrator ID that has access to all Axiom instances (and Tables) that you what to configure the adapter for.
9. Enter and retype the password for the administrator ID in the corresponding fields.
10. Accept the default in the *Context Root* field or enter a different one. This is the context root for the Axiom API. It is case sensitive and must match the value entered during the installation and configuration of the Axiom product. The default value is axiom.

    Note: This field is only shown when the adapter is first configured.

11. Click *Next*

    The Administration - Create a New Axiom EPM Connection window opens.

12. Type the necessary information, test the connection, and if successful, click *Configure*. If not successful, edit the information until the test is successful, then click *Configure*. For more information, see step 4 in *How to Add an Axiom EPM Data Source Instance* on page 346.

    Note: The *Configure* button becomes available once the connection test to the selected RDBMS is successful.

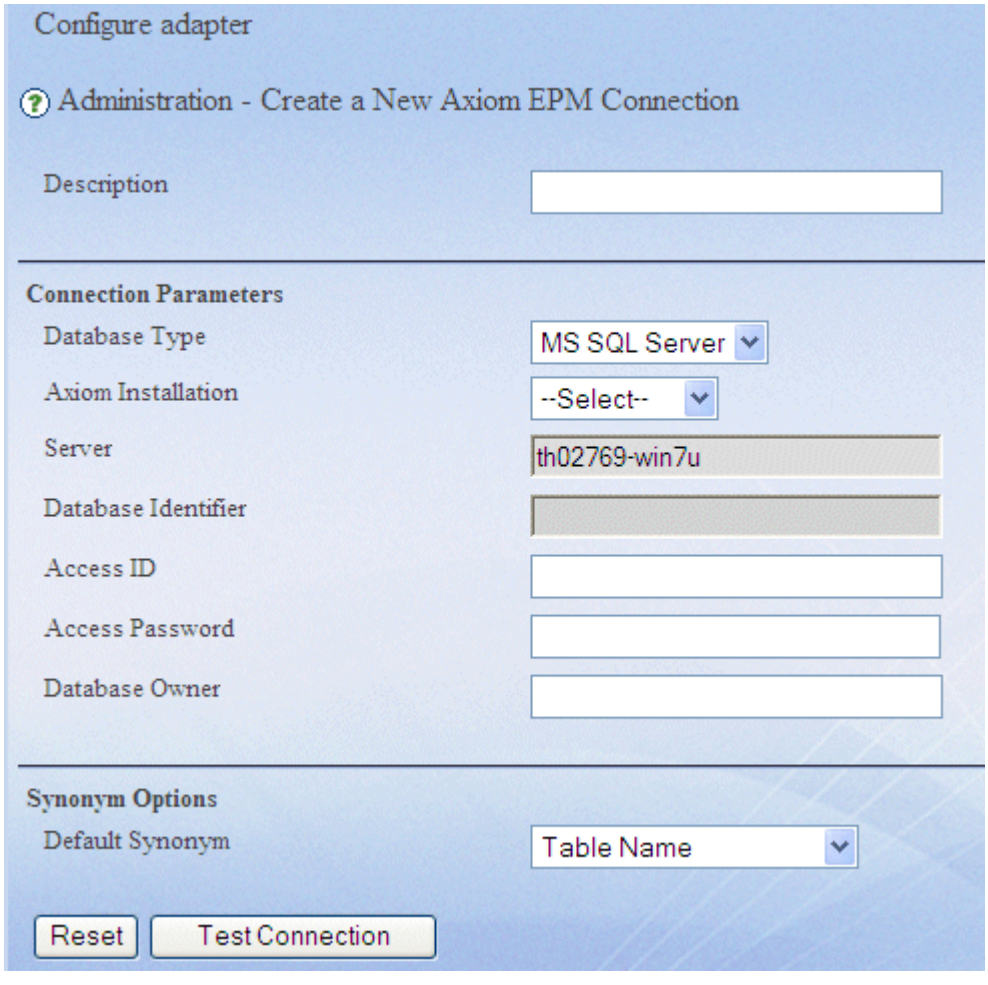
13. Once the configuration finishes, click *Next*.

    Most of the parameters can be changed in the future, but the connection cannot be created without initially supplying correct data source connectivity information. For details on the required information, see *Administration - Create a New Axiom EPM Connection Window* on page 335.

    Tip: A worksheet is provided to assist you in gathering the information you will need to type on this screen. For details, see *Axiom EPM Connection Worksheet* on page 337.

    Once completed, you may begin managing your new Axiom EPM Connection by adding synonyms.

Reference: **Administration - Create a New Axiom EPM Connection Window**



The Administration - Create a New Axiom EPM Connection window contains the following fields/options:

`Description`

Is a description that identifies the current server configuration.

Connection Parameters

`Database Type`

Is the Data source type. The options are: Oracle and MS SQL Server.

`Axiom Installation`

This drop-down box lists available Axiom installations. Select the installation that you will configure. Selecting this value will automatically set the values for the following two options (Server and Database Identifier).

`Server`

Name of the Database Server (for SQL Server only, not Oracle). This is automatically set by your selection for Axiom Installation.

`Database Identifier`

Is the data source identifier or system data source name. This is automatically set by your selection for Axiom Installation.

`Access ID`

Is the RDBMS login ID for data source connectivity. Typically, it is the same login ID Axiom EPM uses to access the data source. There are minimum data access requirements that the ID must have. For details, see *Setting Up the Axiom EPM Access ID* on page 328.

`Access Password`

Is a password associated with the access ID.

`Database Owner`

Is the data source owner identifier or the schema owner depending on your data source. The owner ID is used to fully qualify SQL requests passed to the data source. This allows multiple data source instances or schemas to exist in a single data source. Typical defaults are SYSADM on Oracle and dbo on Microsoft SQL Server.

Synonym Options

`Default Synonym`

Is the name of the synonym to default to when creating new metadata. The options are: Table Name, Table Name with Prefix, Table Name with Suffix.

Note: If you specify any of the options with Prefix or Suffix, the following additional input box is displayed.

`Prefix/Suffix Default`

Enter the prefix or suffix you wish to prepend or append to the name of the synonym. The maximum length for a Prefix/Suffix is nine characters.

Reference: **Axiom EPM Connection Worksheet**

Use the following worksheet to record connection configuration information and keep it for future reference.

Option Name	Response	Description
Description		Row.
Administrator (DBA)		Enter the administrator ID and password that has access to all instances and Tables that are required to be administered by the adapter. Must be consistent across multiple connections.
Database Type		Designation for RDBMS. The options are Oracle and MS SQL Server.
Axiom Installation		Is the installation that you will configure. Selecting this value from the drop-down list will automatically set the values for the following two options (Server and Database Identifier). ❏ Server is the name of the Database Server (for SQL Server only, not Oracle). This is automatically set by your selection for Axiom Installation. ❏ Database Identifier is the data source identifier or system data source name. This is automatically set by your selection for Axiom Installation.
Access ID		ID used by Axiom EPM to connect to the RDBMS.
Access Password		Password associated with the access ID.
Database Owner		Data source owner ID for the Axiom EPM data source.

Option Name	Response	Description
Default Synonym		The name of the synonym to default to when creating new metadata. ❏ Table Name ❏ Table Name with Prefix ❏ Table Name with Suffix **Note:** If you specify any of the options with Prefix or Suffix, an additional input box is displayed for your Prefix or Suffix entry.
Prefix/Suffix Default		Enter the prefix or suffix you wish to prepend or append to the synonym name. The maximum length is nine characters.

Managing Axiom EPM Metadata

The Adapter for Axiom EPM enables management of Axiom EPM metadata. Processes exist that manage the accessibility of Axiom EPM Tables by maintaining the metadata catalog on the reporting server. Before reports can be created or run, this metadata catalog must be created.

You can perform the following tasks to accomplish this:

- ❏ Create synonyms for Axiom EPM Tables.
- ❏ Remove synonyms.
- ❏ Update synonyms.

Accessing the Adapter for Axiom EPM Administrator

To access the environment for administration, you must have access to the Web Console and knowledge of the Axiom administrator ID and password (DBA).

Procedure: How to Access the Adapter for Axiom EPM Administration

1. Open the Web Console.
2. From Web Console sidebar, click *Connect to Data*.
3. In the navigation pane, right-click *Axiom EPM* from the list of configured adapters, and click *Properties*.

4. Type the administrators ID and password, and click *Next*.

   The Axiom EPM menu opens.

Creating Synonyms

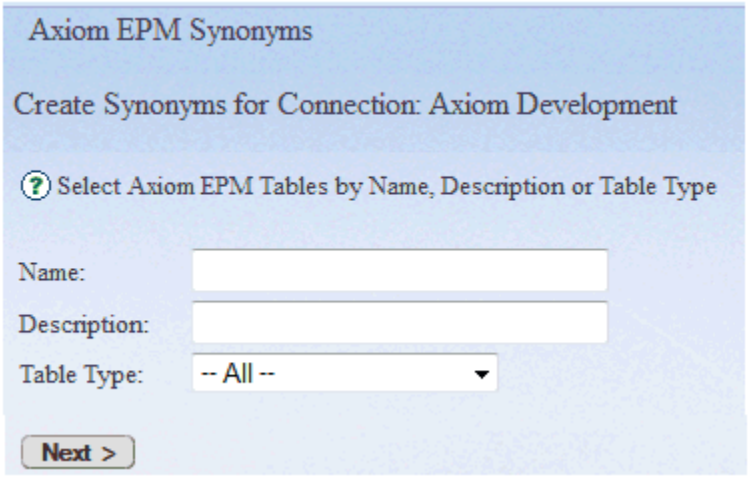
Creating synonyms for Axiom EPM is one of the core functions of the Axiom EPM Administrator. The adapter enables the administrator to choose which Axiom EPM tables are defined in the metadata catalog.

You can create synonyms using a filtered search. A search template option is provided to speed the process of searching for specific Axiom EPM Tables. This is a useful method of locating tables by name, description, or table type.

Procedure: How to Create Synonyms Using a Filtered Search

1. In the Axiom EPM menu, select the connection you want to manage from the *Select Connection* drop-down list. For details on accessing the Axiom EPM menu, see *Accessing the Adapter for Axiom EPM Administrator* on page 338.
2. Click *Create* under the *Synonyms* group.

The Create Synonyms for Connection window opens.



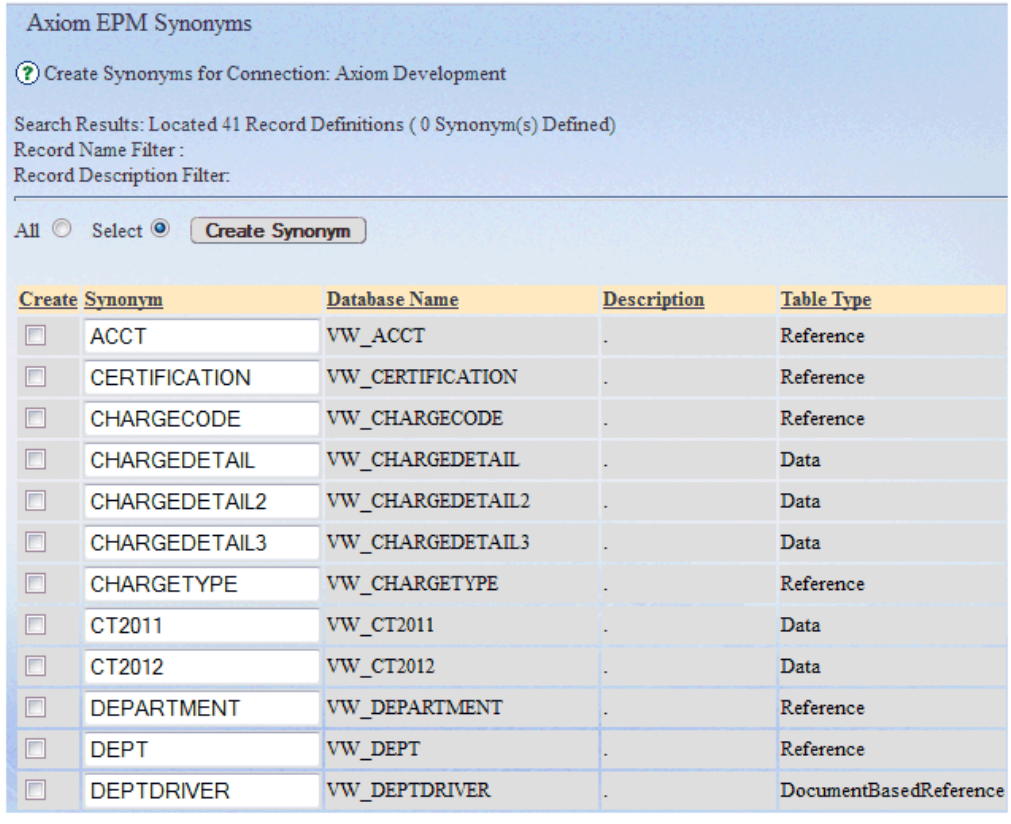
Axiom EPM Tables can be filtered by Name, Description, or Table Type. Provide filter values in the respective fields, or leave the fields blank to see a full list of tables.

Note:

- The Table Description is case-sensitive.
- If you do not use a filter, or your filtered results are very large, the results may be truncated. Use a different filter to reduce the returned results.

3. Click *Next* .

The Create Synonyms for Connection window opens.



Axiom EPM Synonyms

Create Synonyms for Connection: Axiom Development

Search Results: Located 41 Record Definitions (0 Synonym(s) Defined)
Record Name Filter :
Record Description Filter:

All Select Create Synonym

Create	Synonym	Database Name	Description	Table Type
	ACCT	VW_ACCT	.	Reference
	CERTIFICATION	VW_CERTIFICATION	.	Reference
	CHARGECODE	VW_CHARGECODE	.	Reference
	CHARGEDETAIL	VW_CHARGEDETAIL	.	Data
	CHARGEDETAIL2	VW_CHARGEDETAIL2	.	Data
	CHARGEDETAIL3	VW_CHARGEDETAIL3	.	Data
	CHARGETYPE	VW_CHARGETYPE	.	Reference
	CT2011	VW_CT2011	.	Data
	CT2012	VW_CT2012	.	Data
	DEPARTMENT	VW_DEPARTMENT	.	Reference
	DEPT	VW_DEPT	.	Reference
	DEPTDRIVER	VW_DEPTDRIVER	.	DocumentBasedReference

4. Select the check box in the *Create* column for all the Tables you want to create a synonym for, or select *All* to create a synonym for all available Tables.
5. Optionally, change the synonym name in the *Synonym* name column.
6. Click *Create Synonym* to process. Processing may take a few minutes for each selected Record Definition.

Removing Synonyms

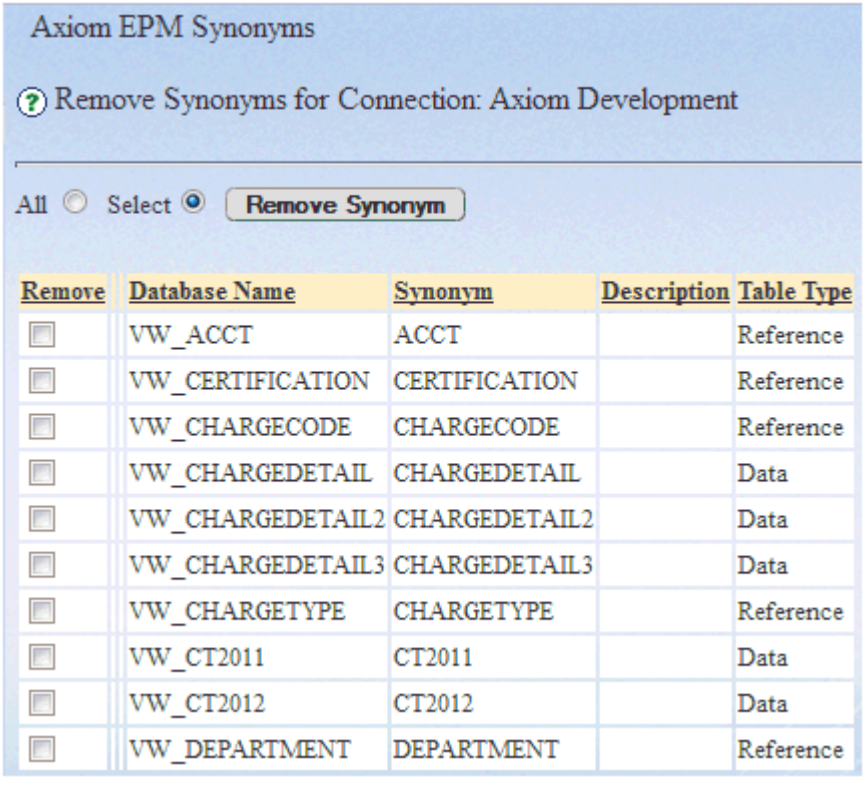
You can remove previously created Axiom EPM synonyms from the metadata catalog with the Remove Synonyms menu option.

Procedure: How to Remove Synonyms

1. In the Axiom EPM menu, select the connection you want to manage from the *Select Connection* drop-down list. For details on accessing the Axiom EPM menu, see *Accessing the Adapter for Axiom EPM Administrator* on page 338.

2. Click *Remove* under the Synonyms group.

   The Remove Synonyms for Connection window opens.



Remove	Database Name	Synonym	Description	Table Type
	VW_ACCT	ACCT		Reference
	VW_CERTIFICATION	CERTIFICATION		Reference
	VW_CHARGECODE	CHARGECODE		Reference
	VW_CHARGEDETAIL	CHARGEDETAIL		Data
	VW_CHARGEDETAIL2	CHARGEDETAIL2		Data
	VW_CHARGEDETAIL3	CHARGEDETAIL3		Data
	VW_CHARGETYPE	CHARGETYPE		Reference
	VW_CT2011	CT2011		Data
	VW_CT2012	CT2012		Data
	VW_DEPARTMENT	DEPARTMENT		Reference

3. Select the check box in the *Remove* column for each synonym you want to remove, or select *All* to remove all available synonyms.
4. Click *Remove Synonym*.

Re-synchronizing Synonyms

You can re-synchronize your metadata. This option:

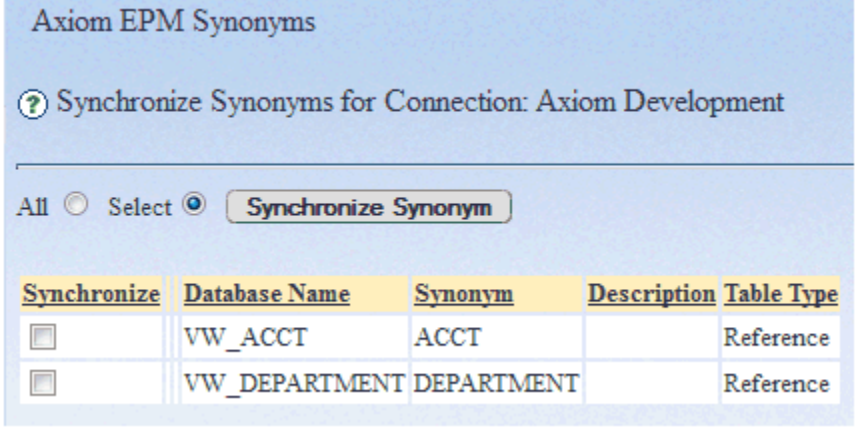
- Queries the internal repository to determine which records were installed for the selected Axiom EPM connection.
- Compares the modified date in those records with the modified date in the Axiom EPM data source. If none of the records have changed, a message appears.

If there are any records that have changed, they appear in the Select Record(s) to Synchronize page.

Procedure: How to Re-synchronize Synonyms

1. In the Axiom EPM menu, select the connection you want to manage from the *Select Connection* drop-down list. For details on accessing the Axiom EPM menu, see *Accessing the Adapter for Axiom EPM Administrator* on page 338.
2. Click *Re-Synch* under the Synonyms group.

   The Synchronize Synonyms for Connection window opens.



3. Select the check box in the Synchronize column for each synonym you want to re-synchronize with Axiom EPM Record Definitions, or select *All* to re-synchronize all listed synonyms.
4. Click *Synchronize Synonym*.

Note: If any changes were made to the Axiom Synonym external of the adapter administration screen, the re-synchronize option will recreate the selected synonym(s) and the changes will be lost.

Refreshing Synonyms

After creating your synonyms, you may need to fresh them at some point.

Procedure: How to Refresh a Synonym

1. From the Axiom EPM menu, select the connection you want to manage from the *Select Connection* drop-down menu. For details on accessing the Axiom EPM menu, see *Accessing the Adapter for Axiom EPM Administrator* on page 338.

2. Click *Refresh* under the *Synonyms* group.

   The Refresh Synonyms for Connection window opens.

3. Select the synonyms you want to fresh under the *Refresh* column, or select the *All* option.
4. Click *Fresh Synonym*.

Note: If any changes were made to the Axiom Synonym external of the adapter administration screen, the re-fresh option will recreate the selected synonym(s) and the changes will be lost.

Viewing Sample Data

After creating a synonym, you may want to verify that it is using the correct Table. The *Synonyms*, *View* option on the Axiom EPM menu provides an easy method for listing the existing synonyms and viewing a sample data set from each.

Renaming a Synonym

You can selectively rename a synonym using the *Synonyms*, *Edit* option on the Axiom EPM menu.

After renaming a synonym, you must update references in existing reports from the old name to the new name using appropriate options in your reporting tool.

Managing Connections to Axiom EPM

Multiple connections to Axiom EPM data sources are possible from within one server configuration. However, depending on your reporting requirements, it may be optimal to create separate configurations for each data source.

Creating multiple connections using the same server configuration is a good option under the following circumstances:

- Two or more Axiom EPM data sources that must be accessed reside on the same system. If the data sources must be accessed for display in a single report output and if the server is located on the same computer system, this architecture can provide optimal performance.
- Two or more Axiom EPM data sources reside in different locations with requirements for moderate to significant consolidated reporting. This architecture provides optimal effectiveness in report development, system maintenance, and performance.

Create separate configurations instead of using multiple connections in these situations:

- Only a single Axiom EPM production data source must be supported. Each development and test instance should have a separate configuration.

- Multiple Axiom EPM data sources exist with only a limited requirement for combining data in reports.

The remaining instructions in this topic assume a single configuration directory structure for one or more data source connections.

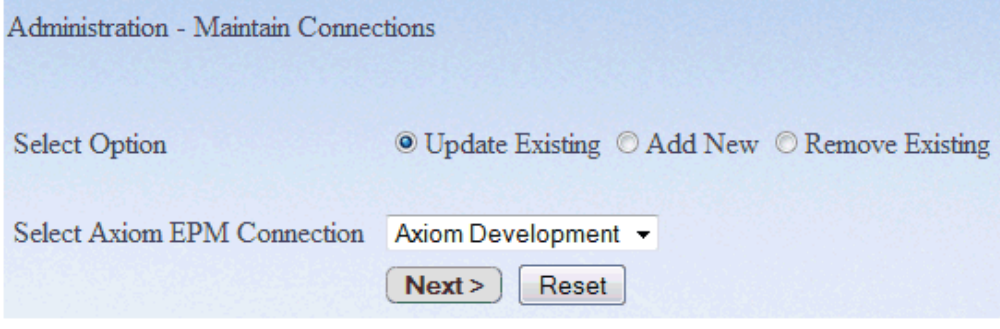
Updating an Axiom EPM Connection

If it becomes necessary to update the connection parameters to an Axiom EPM data source, you can use Administration options to perform these changes.

Procedure: How to Edit an Axiom EPM Connection

1. Click *Connections* under the *Administration* group.

   The Administration - Maintain Connections window opens.



2. Select *Update Existing*.
3. Select a connection from the *Select Axiom EPM Connection* drop-down list.
4. Click *Next*.

   The Administration - Update an Axiom EPM Connection window opens. For details, see *Administration - Create a New Axiom EPM Connection Window* on page 335.

5. Make the necessary modifications, test the connection, and if successful, click *Configure*. If not successful, edit the information until the test is successful, then click *Configure*. For more information, see step 4 in *How to Add an Axiom EPM Data Source Instance* on page 346.

   Note: The *Configure* button becomes available once the connection test to the selected RDBMS is successful.

6. On the next screen, click *Next*.

Adding an Axiom EPM Connection

After you add your first connection, you can specify additional Axiom EPM connections. Note that during this process, you are not prompted for the DBA information prior to managing metadata and connection information since all additional Axiom EPM data sources must use the same DBA in order for base metadata to function properly.

Procedure: How to Add an Axiom EPM Data Source Instance

1. Click *Connections* under the *Administration* group.

   The Administration - Maintain Connections window opens.

2. Select *Add New*.

   Note: If there are currently no connections, *Add* will be the only option.

3. Click *Next*.

   The Administration - Create a New Axiom EPM Connection window opens. For details, see *Administration - Create a New Axiom EPM Connection Window* on page 335.

4. Type the necessary information and click *Test Connection*. If

   - The connection is successful, the following message will appear in green to the right of the button:

     `Connection successful`

   - The connection is unsuccessful, the following message will appear in red to the right of the button with the relevant RDBMS return code:

     `Connection failed - return code: nnnn`

   When the test is successful, the *Configure* button appears.

5. Click *Configure*.
6. On the next screen, click *Next*.

When processing finishes, you can manage your synonyms for this connection.

Removing an Axiom EPM Connection

The integration with Axiom EPM depends on valid connection information. If a previously created connection is no longer required, you should remove that connection.

Procedure: How to Remove an Axiom EPM Connection

1. Click *Connections* under the *Administration* group.

The Administration - Maintain Connections window opens.

2. Select a connection from the *Select Connection* drop-down list.
3. Select *Remove Existing*.
4. Click *Next*.

   The Administration - Remove an Axiom EPM Connection window opens.

   You are prompted to confirm. After confirmation, the system removes the selected Axiom EPM Connection and all of its associated metadata.

Using Administrative Utilities

The Adapter for Axiom EPM provides administrative tools that enable you to report on connection information, update the DBA Password, and set adapter tracing options.

Connection Reports

The Administrator provides reports to make administration easier. You can run reports that provide information on connections and metadata. These reports are accessible from the Administration group menu.

Procedure: How to Run Connection Reports

1. Click *Reports* under the Administration group.

   The Administration - Reports window opens.

2. If necessary, select the Axiom EPM connection you want to run a report for from the *Axiom EPM Connection* drop-down list.

3. Select a report type from the Administration Report drop-down list. The options are:

   - **Connection Information.** Retrieves statistics for the selected connection.
   - **Synonyms.** Retrieves a list of available synonyms for the selected connection.

4. Select an output format for the report from the Output Format drop-down list. The options are HTML and PDF.
5. Click *Run*.

The selected report appears.

Updating the DBA Password

The DBA Password option is used for updating the password that is supplied during the initial configuration of the adapter. When the password is updated, all synonyms are updated as well. (Note that this process may take several minutes.)

Tracing Adapter Processing

The adapter tracing utility creates application level traces for support purposes. Typically, tracing is used under the direction of Information Builders Customer Support Services.

Log off

This option, when clicked, will provide a confirmation dialog box to log off from the adapter and free the server agent. Select *OK* or *Cancel*.

Note: Closing the window will have the same effect (without the confirmation box).

Chapter 13

Using the Adapter for C9 INC

The Adapter for C9 INC provides read access to Salesforce data stored in C9, and supports C9 temporal features by generating fields with temporal properties in the Master File. The adapter converts application requests into C9 INC calls and returns optimized answer sets to the requesting application.

For details about C9 INC-supported data sources, see the *Server Release Notes*.

In this chapter:

Preparing the C9 INC Environment

In order to use the Adapter for C9 INC, you must install the C9 INC driver for whichever data source you would like to access, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the C9 INC Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or Linux location for some C9 INC Driver files to /usr/certive/cjdbc_xx.jar, issue the commands:

   ```
   CLASSPATH=/certive/cjdbc_xx.jar;$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\certive\cjdbc_xx.jar:%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and checking that the special services section displays "JSCOM3 active".

Configuring the Adapter for C9 INC

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a C9 INC data source, the adapter requires connection and authentication information.

The connection credentials for a C9 INC data source are the credentials from the Salesforce account of the user.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one C9 INC data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

or

From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for C9 INC

The *C9 INC* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the C9 INC data source:

```
jdbc:certive://host:port
```

Driver name

Name for the C9 INC driver:

```
com.certive.jdbc.CertiveDriver
```

See driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

The user is authenticated with Explicit authentication. This means that the user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

User

Email address by which you are known to the data source.

Password

Password associated with the email address by which you are known to the data source.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLC9 SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

SQLC9

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection name.

URL

Is the URL to the location of the C9 INC data source.

userid

Is the email address by which you are known to the target database.

password

Is the password associated with the email address by which you are known to the target database.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to data source using the C9 INC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

```
ENGINE SQLC9 SET CONNECTION_ATTRIBUTES CON1
  'jdbc:certive://host:port'
```

Configuring the Adapter

In order to connect to a C9 INC data source, the adapter requires connection and authentication information.

The connection credentials for a C9 INC data source are the credentials from the Salesforce account of the user.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one C9 INC data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLC9 SET DEFAULT_CONNECTION connection
```

where:

`SQLC9`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLC9 SET DEFAULT_CONNECTION SAMPLE
```

Managing C9 INC Metadata

For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLC9 to identify the Adapter for C9 INC.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLC9 [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLC9

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for C9 INC

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Dynamic columns

To specify that the Master File created for the synonym should not contain column information, select the *Dynamic columns* check box.

If this option is selected, column data is retrieved dynamically from the data source at the time of the request.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support Report* on page 365.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for C9 INC synonym comprises a Master File and an Access File. This is a synonym for the table account.

Master File account.mas

```
FILENAME=ACCOUNT, SUFFIX=SQLC9    , $
  SEGMENT=ACCOUNT, SEGTYPE=S0, $
    FIELDNAME=ID, ALIAS=Id, USAGE=A256V, ACTUAL=A256V,
      MISSING=ON, $
    FIELDNAME=ISDELETED, ALIAS=IsDeleted, USAGE=I11, ACTUAL=I4,
      MISSING=ON, $
    FIELDNAME=MASTERRECORDID, ALIAS=MasterRecordId, USAGE=A256V,
ACTUAL=A256V,
      MISSING=ON, $
    FIELDNAME=NAME, ALIAS=Name, USAGE=A256V, ACTUAL=A256V,
      MISSING=ON, $
    FIELDNAME=TYPE, ALIAS=Type, USAGE=A256V, ACTUAL=A256V,
      MISSING=ON, $
    FIELDNAME=PARENTID, ALIAS=ParentId, USAGE=A256V, ACTUAL=A256V,
      MISSING=ON, $
    FIELDNAME=BILLINGSTREET, ALIAS=BillingStreet, USAGE=A256V,
      ACTUAL=A256V, MISSING=ON, $
       .
       .
       .
    DEFINE DAILY_TREND/YYMD  WITH ID TEMPORAL_PROPERTY
TREND=DB_EXPR(INTERVAL '1' DAY);
      TITLE='Daily Trend', $
    DEFINE WEEKLY_TREND/YYMD  WITH ID TEMPORAL_PROPERTY
TREND=DB_EXPR(INTERVAL '1' WEEK);
      TITLE='Weekly Trend', $
    DEFINE MONTHLY_TREND/YYMD  WITH ID TEMPORAL_PROPERTY
TREND=DB_EXPR(INTERVAL '1' MONTH);
      TITLE='Monthly Trend', $
    DEFINE QUARTERLY_TREND/YYMD  WITH ID TEMPORAL_PROPERTY
TREND=DB_EXPR(INTERVAL '1' QUARTER);
      TITLE='Quarterly Trend', $
    DEFINE YEARLY_TREND/YYMD  WITH ID TEMPORAL_PROPERTY
TREND=DB_EXPR(INTERVAL '1' YEAR);
      TITLE='Yearly Trend', $
```

Access File account.acx

```
SEGNAME=ACCOUNT,
   TABLENAME=ads.Account,
   CONNECTION=CON01,
   KEY=ID, $
```

Reference: **Access File Keywords**

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the C9 INC table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* Absence of the CONNECTION attribute indicates access to the default database server.
KEY	Specifies the column that participates in the primary key. The value is always ID: KEY=ID
WRITE	Specifies whether write operations are allowed against the table.

Keyword	Description
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: C9 Temporal Properties

The adapter supports C9 Temporal Analysis by generating fields with temporal properties in the Master File.

For example, by default, CREATE SYNONYM adds the following five fields to the Master File that enable the use of Temporal Analysis supported by C9:

```
DEFINE DAILY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND = DB_EXPR(INTERVAL
'1' DAY); TITLE='Daily Trend', $
DEFINE WEEKLY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND = DB_EXPR(INTERVAL
'1' WEEK); TITLE='Weekly Trend', $
DEFINE MONTHLY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND =
DB_EXPR(INTERVAL '1' MONH); TITLE='Monthly Trend', $
DEFINE QUARTERLY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND =
DB_EXPR(INTERVAL '1' QUARTER); TITLE='Quarterly Trend', $
DEFINE YEARLY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND = DB_EXPR(INTERVAL
'1' YEAR); TITLE='Yearly Trend', $
```

By using one of these fields the user can perform temporal queries against the base tables. For example:

❑ Querying data as of a certain moment in the history of the table. The moment is specified using a WHERE equality test on any of the above fields.

The AS OF time itself can be added to the resulting report by referencing the same field in a BY clause. For example:

```
TABLE FILE OPPORTUNITY
WRITE AMOUNT WHERE DAILY_TREND EQ '2014-01-01'.
```

The resulting SQL query is the following:

```
AS OF DATE '2014-01-01' SELECT SUM(T1."Amount") FROM ads.Opportunity T1.
```

- Issuing a series of temporal queries within a specified range of dates with a specified interval, and plotting the results in a single report, thus obtaining the temporal trend of desired business performance indicators. For example:

```
TABLE FILE ibisamp/OPPORTUNITY WRITE AMOUNT BY QUARTERLY_TREND
WHERE QUARTERLY_TREND FROM '2013-02-01' TO '2015-03-31'
```

The resulting SQL query is the following:

```
TREND FROM DATE '2013-02-01' TO DATE '2015-03-31' BY INTERVAL '1' QUARTER
SELECT CAST(TrendDate() AS DATE), SUM(T1."Amount") FROM ads.Opportunity
T1 GROUP BY CAST(TrendDate() AS DATE) ORDER BY CAST(TrendDate() AS DATE)
```

Please note that instead of DATE constants in the WHERE clause above, you can use DATE expressions based on Dialogue Manager variables such &DATEYYMD, and simplified functions such as DTRUNC and DTADD.

You can specify a trend interval that is different from the five predefined in the synonym, and use it as in the following sample code:

```
DEFINE FILE ibisamp/OPPORTUNITY
BIWEEKLY_TREND/YYMD WITH ID TEMPORAL_PROPERTY TREND = DB_EXPR(INTERVAL 2
WEEK);
END
TABLE FILE ibisamp/OPPORTUNITY
COUNT ID BY BIWEEKLY_TREND ...
```

The following is an example of a Direct SQL Passthru temporal query:

```
SQL SQLC9   /*QUERY*/
 TREND FROM DATE '2013-01-01' TO CURRENT_DATE BY INTERVAL '1' QUARTER
   SELECT
  CAST(TrendDate() AS DATE),
   SUM(T1."Amount")
   FROM
  ads.Opportunity T1
   GROUP BY
  CAST(AsOfDate() AS DATE)
   ORDER BY
  CAST(AsOfDate() AS DATE);
END
```

Note: In order for a query against a C9 synonym with a temporal field (a field with TEMPORAL_PROPERTY TREND) to make business sense the following restrictions apply.

- Only one temporal field should be mentioned in a TABLE query.
- The field should be used in a sort phrase (BY or ACROSS).
- Temporal fields should not be objects of the WRITE or PRINT commands.
- Temporal fields should not be used in DEFINE or COMPUTE commands.
- If no temporal fields are referenced in a query, the results are returned as of the current date.
- It is recommended that the query contain a WHERE test on a temporal field. The following tests are allowed:
  - Single-point EQ,
  - Single-interval FROM-TO, GE, LE.

    Boundaries assumed by default, if not specified by a single-point EQ or FROM-TO test, are as follows:

    The lower boundary is the start of the UNIX epoch, that is, 01/01/1970.

    The upper boundary is the current date.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the following options.

Option	Description
Open	Opens the Master File for viewing and editing using a graphical interface. If an Access file is used it will be also available.
Edit as Text	Enables you to view and manually edit the Master File synonym. **Note:** To update the synonym, it is strongly recommended that you use the graphical interface provided by the *Open* option, rather than manually editing the Master File.

Option	Description
Edit Access File as Text	Enables you to view and manually edit the Access File synonym. **Note:** This option is available only when an Access File is created as part of the synonym.
Sample Data	Retrieves up to 20 rows from the associated data source.
Data Profiling	Data Profiling provides the data characteristics for synonym columns. Alphanumeric columns provide the count of distinct values, total count, maximum, minimum, average length, and number of nulls. Numeric columns provide the count of distinct values, total count, maximum, minimum, average value, and number of nulls.
Refresh Synonym (if applicable)	Regenerates the synonym. Use this option if the underlying object has been altered.
Impact Analysis	Generates reports on procedures, synonyms, and columns that provide information on the flows/stored procedures available on a particular server, and the synonyms and columns they use. These reports enable you to evaluate changes before they are made by showing which components will be affected. See the *Server Administration* manual for details about Impact Analysis reports.
Copy	Copies the synonym to the clipboard.
Delete	Deletes the synonym. You are asked to confirm this selection before the synonym is deleted.
Cut	Deletes the synonym and places it on the clipboard.
Properties	Displays the properties of the synonym, including physical location, last modified date, description, and privileges.

Data Type Support Report

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Customizing the C9 INC Environment

The Adapter for C9 INC provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to C9 INC.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLC9 SET TIMEOUT {nn|0}
```

where:

`SQLC9`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a timeout occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native C9 INC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Chapter 14

Using the Adapter for Caché

The Adapter for Caché allows applications to access Caché data sources. The adapter converts application requests into native Caché statements and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the Caché Environment (ODBC)

In order to use the adapter, the Caché client must be installed on the box where the server will be running.

Procedure: How to Set up the ODBC Environment on Windows

On Windows, the Caché environment is set up during the installation of the product.

Procedure: How to Set Up the ODBC Environment on UNIX

To set up the Adapter for Caché environment on UNIX, export the following environment variables:

- **Caché_HOME.** Specify the full name of the directory in which Caché is installed. For example:

  ```
  Cache_HOME=/rdbms/Cache
  ```

- **ODBCINI.** Specify the location of the ODBC initialization file. For example:

  ```
  ODBCINI=/odbms/Cache/Cachex.ini
  ```

Preparing the Caché Environment (JDBC)

In order to use the Adapter for JDBC, you must install the JDBC driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the JDBC Environment on Windows and UNIX

1. Identify the location of the JDBC Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;
   $CLASSPATH
   export CLASSPATH
   ```

   On UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

2. Start, or restart, the server.

   You must also restart the server if the driver has changed.

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace and checking that the special services section displays *JSCOM3 active*.

   ```
   edastart -show
   ```

   If the JSCOM3 service is not active, a *fail to start* message will typically also be inserted in the server EDAPRINT log. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for Caché

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to the Caché database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user*.prf), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user*.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Caché database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Caché Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Caché (ODBC)

The *Caché* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

Caché data source name (DSN). This is no default data source name. You must enter a value.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually (ODBC)

```
ENGINE SQLISM SET CONNECTION_ATTRIBUTES connection
       DSN_name/userid,password
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and DSN_*name*.

`DSN_`*`name`*

Is the Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

`userid`

Is the primary authorization ID by which you are known to the adapter.

`password`

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Caché DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLISM SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```

Reference: Connection Attributes for Caché (JDBC)

The Cache adapter is under the SQL group folder. The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Is a logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Is the URL pointing to the location of the JDBC data source.

Driver name

Is the name of the JDBC driver.

For information, see the driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names that will be available for Java Services. This value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field.

When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Syntax: How to Declare Connection Attributes Manually (JDBC)

```
ENGINE SQLISM SET CONNECTION_ATTRIBUTES connection 'url'/userid,password
```

where:

`SQLISM`
Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`
Is the connection name.

`'url'`
Is the URL to the location of the JDBC data source.

`userid`
Is the primary authorization ID by which you are known to the target database.

`password`
Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes (JDBC)

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the JDBC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

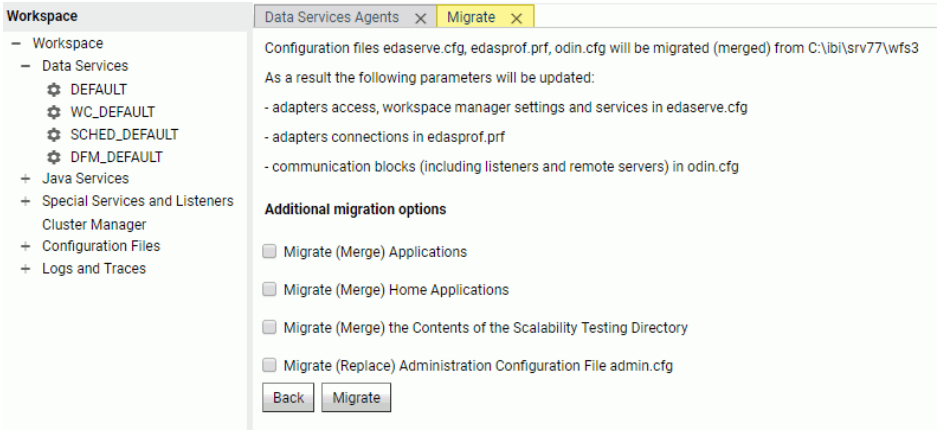
```
ENGINE SQLISM SET CONNECTION_ATTRIBUTES CON1
'jdbc:xxxxxxx://hostname:port/datasource'/MYUSER,PASS
```

Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to a newer release. To access this option, click *Workspace* from the sidebar, then *Migrate* on the ribbon, or right-click *Workspace* on the resources tree, then click *Migrate* on the context menu. This is the recommended approach.

On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click *Continue*. Select additional migration options, as shown in the following image, and click *Migrate*



If you choose *not* to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=*value*.

  For example, suppose that prior to Version 7 Release 6.1, the connection was defined as:

  ```
  ENGINE SQLISM SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
  ```

  When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

  ```
  CONNECTION=DSN_A
  ```

  If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

  ```
  ENGINE SQLISM SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
  ```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLISM SET DEFAULT_CONNECTION connection
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLISM SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLISM SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMAND`

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Caché Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Caché data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLISM to identify the Adapter for Caché.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLISM [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLISM

Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using Caché, you must locally install the RDBMS Caché Driver.

The Server can access third-party database tables across the network Caché. You must provide a system data source name and possibly a user ID and/or password for the database tables you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

Synonyms define unique names (or aliases) for each Caché table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.

- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Caché

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Caché synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLISM ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DB1,KEYS=1,$
```

Reference: Access File Keywords

This chart describes keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Caché table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local Caché database server. Absence of the CONNECTION attribute indicates access to the default database server.
DBSPACE	Optional keyword that indicates the storage area for the table. For example: *datasource.tablespace* DATABASE *datasource*
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.

Keyword	Description
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support

Data types are specific to the underlying data source.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the Caché Environment

The Adapter for Caché provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Caché.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLISM SET TIMEOUT {nn|0}
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLISM SET PASSRECS {ON|OFF}
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Specifying the Transaction Isolation Level

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

Syntax: How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

```
ENGINE SQLISM SET ISOLATION {RU|RC|RR|SE}
```

where:

`SQLISM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`RU`

Sets the transaction isolation level to Read Uncommitted.

`RC`

Sets the transaction isolation level to Read Committed.

`RR`

Sets the transaction isolation level to Repeatable Read.

`SE`

Sets the transaction isolation level to Serializable Read.

Caché Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 15

Using the Adapter for CICS Transactions

The Adapter for CICS Transactions processes input parameters, creates and sends requests to the CICS Transaction Server, and creates an answer set based on the received response.

This adapter supports the following transport layers:

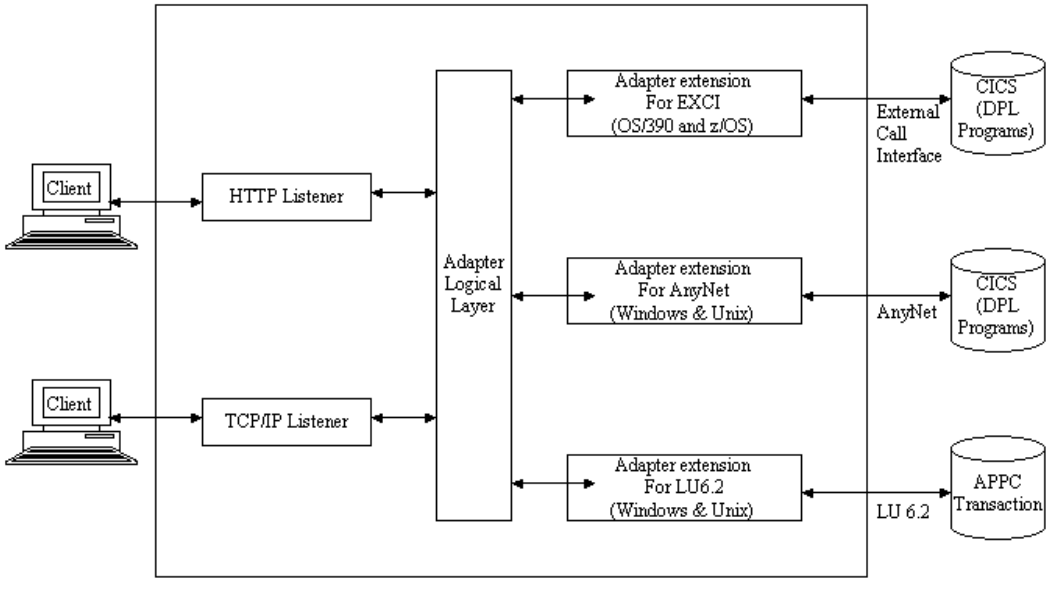
- EXCI for z/OS platforms.
- TCP62 using AnyNET for UNIX and Microsoft Windows platforms.
- TCP/IP for UNIX, Microsoft Windows, and z/OS platforms.
- LU6.2 for UNIX, Microsoft Windows, and z/OS platforms.

Note: Throughout this chapter, the CICS Transaction Server is referred to as CICS Transactions.

In this chapter:

Preparing the CICS Environment

The following diagram illustrates the basic flow of a CICS transaction. It illustrates how the client application communicates with the adapter.



The communication to the CICS Transactions region depends upon the platform the adapter is running on. If you are using UNIX or Microsoft Windows, you can use a communication transport of TCP62 (AnyNET) for DPL programs or LU6.2 for APPC programs. If you are using z/OS, a direct CICS Transactions External Call Interface is used for DPL programs (use of LU6.2 for APPC programs from z/OS is not supported in this release of the server).

To provide for transparent execution of CICS Transactions programs, metadata describing the program input and output areas is held on the server. For DPL programs, the COBOL FD describing DFHCOMMAREA is used as a source for metadata creation. For APPC-based programs, the COBOL FD describing the storage layout for CICS Transactions SEND and RECEIVE calls is used as a source for metadata creation; RECEIVE for input, SEND for output.

A Web Console is available as the primary configuration and maintenance tool. It is used to add or change adapter communication parameters and in creating/maintaining the metadata associated with the programs to be executed.

CICS Transactions Adapter Supported Platforms and Release Information

The following platforms are supported: Microsoft Windows, UNIX, and z/OS.

For Microsoft Windows and UNIX based servers that use AnyNET or LU6.2 to communicate with any CICS Transactions region, the following minimum software release levels on a target are required:

- z/OS Version 1.4 or higher.
- CICS Transactions Version 4 or higher.
- TCP/IP Direct Access, CICS TS 2.3 or higher.

Note: To use TCP62 or AnyNET, all VTAM options for AnyNET or TCP62 must be configured and AnyNET must be active.

For z/OS based servers, the following minimum software release levels are required:

- z/OS Version 1.4 or higher
- CICS Transactions Version 4 or higher

Note: Because the EXCI option is being used, the adapter can only communicate with CICS Transactions regions that are running on the same LPAR. Also, the STEPLIB of the IRUNJCL JCL member of the configuration data set needs to include the CICS Transactions SDFHEXCI library.

CICS and VTAM Configuration

These topics provide the setup and communications configuration information the adapter requires to communicate with CICS Transactions.

After you configure any VTAM definitions, the major nodes they describe need to be started in the VTAM system. If you are using AnyNET, it should be tested from the Adapter for CICS Transactions platform.

AnyNET VTAM Definitions

The AnyNET product requires three major VTAM nodes for its operation. The following are examples of those nodes. Replace relevant parameters with your site specific values.

Example: **Setting Up the Major Node for the AnyNET Listener**

```
**********  TCP62 MAJOR NODE DEFINITION FOR ANYNET
TCP62   VBUILD TYPE=TCP,DNSUFX=IBI.COM,PORT=397
TCP62G  GROUP  ISTATUS=ACTIVE
TCP62L  LINE   ISTATUS=ACTIVE
TCP62P  PU     ISTATUS=ACTIVE,NETID=MYNET
```

Note: Port 397 is used in this example. On UNIX, using a port number above 1000 is recommended due to the root privileges associated with using a port number under 1000. On z/OS, 397 is the default port. It is well established and frequently used.

Keep in mind, however, that the port you use must be the same on UNIX and z/OS. For example, if 1000 is specified on one platform, it must also be specified on the other.

Example: Setting Up the Major Node for Cross Domain Resources

If CDRDYN=YES is not specified in the ATCSTR00 VTAM startup parameter file, then the name of the machine that the Transaction adapter is running on needs to be coded in the follow node:

```
        VBUILD TYPE=CDRSC
CDRSC62 NETWORK NETID=MYNET
CDRSC62 GROUP
EDABGR2 CDRSC ALSLIST=TCP62P
```

Note: EDABGR2 is the machine name on which the server is running. The machine name must be limited to eight bytes.

Example: Setting Up the Standard VTAM LU Definitions

```
        VBUILD TYPE=SWNET
MYNAMEPU  PU   ADDR=01,IDBLK=05D,IDNUM=10101,                X
               MAXPATH=3,                                    X
               PUTYPE=2,                                     X
               MODETAB=MTOS2EE,                              X
               DLOGMOD=PARALLEL,                             X
               ISTATUS=ACTIVE
MYLUNAME  LU   LOCADDR=2
```

LU6.2 VTAM Definitions

LU6.2 requires two major VTAM nodes for its operation. The main node for AnyNET identifies the port. The following are examples of these two nodes. Replace relevant parameters with your site specific values.

Example: Setting Up the Major Node for the AnyNET Listener

```
**********  TCP62 MAJOR NODE DEFINITION FOR ANYNET
TCP62   VBUILD TYPE=TCP,DNSUFX=IBI.COM,PORT=397
TCP62G  GROUP  ISTATUS=ACTIVE
TCP62L  LINE   ISTATUS=ACTIVE
TCP62P  PU     ISTATUS=ACTIVE,NETID=MYNET
```

Note: Port 397 is used in this example. On UNIX, using a port number above 1000 is recommended due to the root privileges associated with using a port number under 1000. On z/OS, 397 is the default port. It is well established and frequently used.

Keep in mind, however, that the port you use must be the same on UNIX and z/OS. For example, if 1000 is specified on one platform, it must also be specified on the other.

Example: Setting Up the Standard VTAM LU Definitions

```
        VBUILD TYPE=SWNET
MYNAMEPU  PU   ADDR=01,IDBLK=05D,IDNUM=10101,                X
               MAXPATH=3,                                    X
               PUTYPE=2,                                     X
               MODETAB=MTOS2EE,                              X
               DLOGMOD=PARALLEL,                             X
               ISTATUS=ACTIVE
MYLUNAME  LU   LOCADDR=2
```

CICS Connection and Sessions for Microsoft Windows and UNIX

For the adapter to be able to connect to CICS (for both TCP62 and LU6.2 where supported), connection and session definitions are required. The definitions are dependent on the platform on which the adapter is running.

If you deploy the adapter on Microsoft Windows or UNIX, the connection and sessions definitions described in *Using the CEDA View Connection Command* on page 391 and *Using the CEDA View Sessions Command* on page 392 are required.

Note: For DPL program execution, all users must be able to access and run transaction CPMI (the mirror transaction).

Example: Using the CEDA View Connection Command

The following is an example of a CEDA view connection command that illustrates what is required:

```
CEDA  View Connection(  MYLU )
   Connection    :  MYLU
   Netname       :  MYLUNAME
   ACcessmethod  :  Vtam          Vtam  | IRc  | INdirect | Xm
   PRotocol      :  Appc          Appc  | Lu61 | Exci
   SInglesess    :  No            No    | Yes
   DAtastream    :  User          User  | 3270 | SCs | STrfield | Lms
   INService     :  Yes           Yes   | No
   ATtachsec     :  Verify        Local | Identify | Verify | Persistent
```

Example: Using the CEDA View Sessions Command

The following is an example of a CEDA view sessions command that illustrates what is required:

```
CEDA View Sessions(  MYLUNAME )
   Sessions      :  MYLUNAME
   Connection    :  MYLU
   MOdename      :  PARALLEL
   Protocol      :  Appc               Appc | Lu61 |
   MAximum       :  008 , 000          0-999
```

The MAximum parameter determines the number of concurrent sessions available to process requests. Its first value should be in the range of 4 - 255, and the second one should always be set to zero.

Note: Log mode must support parallel sessions.

Configuring the Adapter for CICS Transactions

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. In addition, for if you are using the TCP 62 or LU 6.2 communication protocols, you must configure a Listener node.

Configuring Communications Parameters for TCP 62 and LU 6.2

This procedure is required if you are using TCP 62 or LU 6.2 as your communications protocol.

Note that you can complete this step either *before* or *after* you declare connection attributes.

Procedure: How to Configure a Listener

Note: This step is required if you are using TCP 62 or LU 6.2 on Windows or UNIX.

1. From the Web Console menu bar, select *Workspace* then *Configuration*.
2. On the expanded menu bar, select *New*, then *Listener*, and *CICST*. The Listener Configuration pane opens.
3. Type the appropriate values for the communications parameter.

   For descriptions of these parameters, see *Communications Parameters for CICS Transactions for TCP 62 or LU 6.2* on page 393.

   Tip: You can also obtain details about each entry by clicking the *?* icon to the left of any parameter field on the communications configuration pane to access the Web Console Help.
4. Click *Save and Restart*.

Reference: **Communications Parameters for CICS Transactions for TCP 62 or LU 6.2**

This chart describes the parameters required to configure communications. To complete the configuration, click *Save and Restart Listener*.

Keyword	Description
NODE	8-character string Defines a logical name of a node block, which must be unique in the file. The logical name can be a maximum of eight characters, must begin with a letter, and can include any characters, except semicolon and equal sign. A node block contains keyword-value pairs, which are enclosed in a BEGIN-END statement.
PARTNER_LU_NAME	string Defines the APPLID of the target CICS region.
LOCAL_LU_NAME	string Defines the LU name to be used. This value is taken from an LU entry in the major node. The value is also specified in the CICS connection/sessions definition.
MODE_NAME	string Defines the DLOGMODE parameter value.
CODEPAGE	string Defines the code page that the CICS region is using.
COMMUNICATION	Select one of the following options: ❑ TCP/IP for DPL program execution. This option displays additional parameters required for TCP 62. ❑ LU6.2 for APPC program execution. **Important:** Your selection in this field determines what additional configuration information that is required.
Additional required information for TCP/IP (This option displays additional parameters required for TCP 62.)	

Keyword	Description
VTAM_NETWORK_ID	string Defines the VTAM network ID. This value is taken from the AnyNET listener major node under parameter NETID.
CONNECT_LIMIT	number of seconds Defines the maximum time, in seconds, that the client waits for a connection response from the AnyNET environment. Provide a value greater than 0. (Do not enter a value of -1.)
PROXY	string Defines the name of the supplied proxy (user-written) program, which converts the Full Function Server calling syntax to the syntax that is valid for the CICS program to be executed. This parameter is *optional*, and should be left blank for normal operations. Use it only at the direction of your local support personnel.
MIRROR	string Defines the IBM-supplied mirror transaction CPMI that the Adapter for CICS Transactions calls by default. If this transaction cannot be used, you can create another transaction name to point to the IBM-supplied mirror program DFHMIRS. Enter the alternate name in the MIRROR field.
NATPROG	string Identifies the NATURAL program to be executed. **Note:** This option does not apply to the Adapter for CICS Transactions.
HOST	string Defines the host that a client is connecting to or an IP address that a listener is listening on.

Keyword	Description
SERVER_ID	string Defines the machine name where the server is configured with the CICS AGENT NODE (Listener).
ANYNET_PORT	positive integer number Defines the port number that the AnyNET product is using. The default AnyNET port is 397, but any number can be used. For UNIX installations, a port number above 1000 is recommended.
Additional required information for LU6.2	
PROXY	string Defines the name of the supplied proxy (user-written) program, which converts the Full Function Server calling syntax to the syntax that is valid for the CICS program to be executed. This parameter is *optional*, and should be left blank for normal operations. Use it only at the direction of your local support personnel.
SIDE_INFO	string SIDE_INFO is a table with definitions for all partners to the currently active CICS system. CICS implements the side information table by means of the PARTNER resource. Partner resources are defined by the CEDA DEFINE command. To become known to an active CICS system, a defined partner resource must be installed using the CEDA INSTALL command.
HOST	string Defines the DNS name of the host LPAR of the target CICS region. You can also code the four part IP address.

Example: Sample Node Definitions Using LU6.2

```
NODE = CICSTLU6
BEGIN
  PROTOCOL = CICS
  CLASS = CICSCLIENT
  TARGET = CICS
  PARTNER_LU_NAME = EDBGM010
  LOCAL_LU_NAME = T29DPB41
  MODE_NAME = PARALLEL
  HOST = IBIMVS
  CODEPAGE = 037
  COMMUNICATION = LU62
END
```

Example: Sample Node Definitions Using TCP/IP (TCP 6.2)

```
NODE = LST_CICS
BEGIN
  PROTOCOL = CICS
  PORT = 8139
  CLASS = AGENT
END
NODE = SPGCSRV
BEGIN
  PROTOCOL = CICS
  PORT = 8139
  CLASS = AGENT
  TARGET = INTERNAL
  HOST = IBIMVS
  CODEPAGE = 037
  ANYNET_PORT = 397
END
NODE = CICSCLNT

BEGIN
  PROTOCOL = CICS
  CLASS = CLIENT
  TARGET = CICS
  INTEGER = HOBF
  FLOAT = IBM
  PARTNER_LU_NAME = EDBGM010
  LOCAL_LU_NAME = T29DPB04
  MODE_NAME = PARALLEL
  HOST = SPGCSRV
  CODEPAGE = 037
  COMMUNICATION = TCP
  VTAM_NETWORK_ID = USIBINET
  CONNECT_LIMIT = 60
  MIRROR = CPMI
  ATTACH_SECURITY = VERIFY
  SECURITY = C2B591CC2A92650028E8A570F3BE36F3
END
```

Configuring the Adapter

In order to connect to CICS Transactions, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one data source by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to CICS Transactions takes place when the first query that references that connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the last SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the last SET CONNECTION_ATTRIBUTES command.

For detailed instructions about declaring connection attributes for your operating system, see *Configuring the Adapter on Microsoft Windows and UNIX* on page 397 or *Configuring the Adapter on z/OS* on page 401.

Configuring the Adapter on Microsoft Windows and UNIX

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish. In addition, if you are using the TCP 62 or LU 6.2 communications protocol, you must configure a Listener node as described in *How to Configure a Listener* on page 392. For TCP/IP, you only need to declare connection attributes.

Procedure: How to Configure the Adapter on Windows and UNIX

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Select a communications protocol: *TCP 62*, *LU 6.2*, or *TCP/IP* and click *Next*.

   For TCP/IP, the configuration parameters for the adapter are displayed.

   For TCP 62 and LU 6.2, you are prompted to either *Configure CICST listener* or to click *Next* to display the configuration parameters for the adapter. You can complete these tasks *in either order*, but both must be done to use the adapter.

   - If you click *Next*, the configuration parameters are displayed. However, in this scenario, you must then configure a Listener node, as described in *How to Configure a Listener* on page 392.
   - If you click Configure CICST listener, the Web Console opens at the Special Services pane. For instructions, see *How to Configure a Listener* on page 392.

     Once you have configured the Listener, return to the Add CICS Transaction to Configuration pane, where the Listener node is now available for selection.
6. Enter values for the parameters required by the adapter as described in the connection attributes reference.
7. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for CICS Transactions on Windows and UNIX

The CICS Transaction adapter is under the *Procedures* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Communication Protocol

Select one of the following: TCP/IP, TCP 62, LU 6.2. Subsequent options vary slightly depending on this selection.

Note: For TCP 62 and LU 6.2, you must configure a Listener either before or after you declare connection attributes.

This selection is reflected in the Communication field on the second configuration pane.

Connection name

Is a logical name used to identify a specific set of connection attributes.

Node name

For TCP 62 or LU 6.2, a drop-down list of nodes is displayed if the Listener has already been configured. Select a node from the list.

Host name

For TCP/IP, enter the name of the host machine.

Application ID

For TCP 62 or LU 6.2, enter the application ID of the CICS Transactions region.

Mirror

Enter the name of the mirror transaction.

Port

For TCP/IP, enter the port number.

Security

There are two methods by which a user can be authenticated when connecting to the Adapter for CICS Transactions:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the adapter, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to CICS Transactions, at connection time, for authentication.

User

Is the user name by which you are known to the adapter. This field is only displayed when the security mode of the server is non-trusted.

Password

Is the password associated with the user name. This field is only displayed when the security mode of the server is non-trusted.

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down list and enter a name in the Profile Name input box. (The extension is added automatically.)

Syntax: How to Declare Connection Attributes Manually on Windows and UNIX

Explicit. The user ID and password are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users.

```
ENGINE CICSTRAN SET CONNECTION_ATTRIBUTES [connection]
  [node_name]/userid,password: "parameters_list"
```

Password passthru. The user ID and password are explicitly specified for each connection and passed to CICS Transactions, at connection time, for authentication.

```
ENGINE CICSTRAN SET CONNECTION_ATTRIBUTES [connection]
  [node_name] /: "parameters_list"
```

where:

`CICSTRAN`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION=connection_name value. See *Access File Attributes* on page 411.

`node_name`

Is a name of the NODE definition in the ODIN configuration file.

`userid`

Is the primary authorization ID by which you are known to the Adapter for CICS Transactions.

`password`

Is the password associated with the primary authorization ID.

parameters_list

The following parameters are supported (some required; some optional):

application_ID is the application ID of the CICS region. This parameter is optional.

mirror_name is the name of the mirror transaction. This value overwrites the MIRROR value provided when the Listener is configured. This parameter is optional.

communication is the communication protocol being used. The options are: TCP/IP, TCP 6.2 (AnyNET), LU 6.2.

Configuring the Adapter on z/OS

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Adapter on z/OS

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Select a communications protocol: *TCP/IP* or *EXCI* and click *Next*.

   The configuration parameters for the adapter are displayed.

6. Enter values for the parameters required by the adapter as described in the connection attributes reference.

7. Click *Configure*. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for CICS Transactions on z/OS

The CICS Transaction adapter in under the *Procedures* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Communication Protocol

Select one of the following: *TCP/IP* or *EXCI*. Subsequent options vary slightly depending on this selection.

This selection is reflected in the Communication field on the second configuration pane.

Connection name

Is a logical name used to identify a specific set of connection attributes.

Host name

For TCP/IP, enter the name of the host machine.

Application ID

For EXCI, enter the application ID of the CICS region.

Port

For TCP/IP, enter the port number.

Mirror

Is the name of the mirror transaction. The default value is EXCI.

This value overwrites the value provided in the Listener mode.

Security

For EXCI, Trusted security is supported under the following conditions: the server must be running with security OPSYS and IRC (Inter Region Communications) must be active in the CICS region. The adapter then connects to the CICS region using the credentials of the operating system user impersonated by the server data access agent.

For TCP/IP, there are two methods by which a user can be authenticated when connecting to the Adapter for CICS Transactions:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the adapter, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to CICS Transactions, at connection time, for authentication.

User

Is the user name by which you are known to the adapter. This field is only displayed when the security mode of the server is non-trusted.

Password

Is the password associated with the user name. This field is only displayed when the security mode of the server is non-trusted.

Select profile

The level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down list and enter a name in the Profile Name input box. (The extension is added automatically.)

Syntax: How to Declare Connection Attributes Manually on z/OS

Explicit. The user ID and password are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users.

```
ENGINE CICSTRAN SET CONNECTION_ATTRIBUTES [connection]
  [node_name]/userid,password: "parameters_list"
```

Password passthru. The user ID and password are explicitly specified for each connection and passed to CICS Transactions, at connection time, for authentication.

```
ENGINE CICSTRAN SET CONNECTION_ATTRIBUTES [connection]
  [node_name] /: "parameters_list"
```

Trusted. The adapter connects to an operating system login using the credentials of the operating system user impersonated by the server data access agent.

```
ENGINE CICSTRAN SET CONNECTION_ATTRIBUTES [connection]
  [node_name] /: "parameters_list"
```

where:

`CICSTRAN`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is a logical name used to identify this particular set of connection attributes. In the Access File, it becomes the CONNECTION=connection_name value. See *Access File Attributes* on page 411.

node_name

Is a name of the NODE definition in the ODIN configuration file.

userid

Is the primary authorization ID by which you are known to the Adapter for CICS Transactions.

password

Is the password associated with the primary authorization ID.

parameters_list

The following parameters are supported (some required; some optional):

application_ID is the application ID of the CICS region. This parameter is optional.

mirror_name is the name of the mirror transaction. This value overwrites the MIRROR value provided when the Listener is configured. This parameter is optional.

communication is the communication protocol being used. The options are: TCP/IP and EXCI.

Managing CICS Transaction Metadata

When the server invokes a transaction or procedure, it needs to know how to build the request, what parameters to pass, and how to format an answer set from the response. For each transaction the server will execute, you must create a synonym that describes the layout of the request/response area.

Creating Synonyms

Synonyms define unique names (or aliases) for each transaction or procedure that is accessible from the server. Synonyms are useful because they hide the underlying transaction or procedure from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows the input parameters and the response layout to be moved while allowing client applications to continue functioning without modification. For example, moving a transaction or procedure from a test region to production. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Web Console or the Data Management Console.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

   - For Windows and UNIX, see *Synonym Creation Parameters for CICS Transactions on Windows and UNIX* on page 406.
   - For z/OS, see *Synonym Creation Parameters for CICS Transactions on z/OS* on page 408.
4. After entering the parameter values, click *Create Synonym*.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the *Validate* check box, the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: **Synonym Creation Parameters for CICS Transactions on Windows and UNIX**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Collection of COBOL definitions

Select *Collection of COBOL* definitions and type the location of a collection of Cobol Copybooks. If you select this option you can choose all COBOL definitions in the collection (%) or filter by name and extension.

File name/File extension

If you wish to limit retrieval, you can enter a file name and/or file extension:

- In the File name box, enter a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.
- In the File extension box, enter an extension with or without the wildcard symbol %.

Synonym name

Type the name of the synonym in the Synonym name box.

Program name

Type the name of the CICS Transactions program or APPC transaction in the Program name box.

COMMAREA

Enter a COMMAREA value: type CALC in the input box to indicate maximal segment size or enter a value that represents the physical length of the data. The default value is 32500.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select tables for synonyms

The Cobol Copybook(s) appear on the screen. You can choose the same Copybook or different Copybooks for input and output parameters.

Note: There can be no more than one set of input/output Copybooks per synonym.

Reference: Synonym Creation Parameters for CICS Transactions on z/OS

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

File System Selection

Choose one of the following options from the drop-down list:

- *Fully qualified PDS name* to indicate a partitioned data set on MVS.

  In the input boxes provided, type a PDS name preceded by // and a Member name containing the location of the COBOL FD source. If you wish, you can filter the member name using a wildcard character (%).

  or

- *Absolute HFS directory pathname* to indicate a hierarchical file structure on USS.

  In the input boxes provided, type a Directory name to specify the HFS location that contains the COBOL FD and a File name and File extension. If you wish, you can filter the file and extension using a wildcard character (%).

Target Program type

Choose an option from the drop-down list:

- Dynamic Program Link
- TP Gateway (for migration)
- Stored Procedure Gateway (for migration)

Note: The last two options support older style program types (TPG/SPG/ASS) for which migration may be necessary. For details about migration, see the *ServerRelease Notes*.

COBOL FD available for the answer set

Check this box if you want to use COBOL file descriptions for your Master Files.

Synonym name

Type the name of the synonym in the Synonym name box.

Program name

Type the name of the CICS Transactions program or APPC transaction in the Program name box.

COMMAREA

Enter a COMMAREA value: type CALC in the input box to indicate maximal segment size or enter a value that represents the physical length of the data. The default value is 32500.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Input Segment Definition

Is the name of the COBOL FD file that contains information about input parameters.

There can be no more than one set of input COBOL Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Output Segment Definition

Is the name of the COBOL FD file that contains information about output parameters.

There can be no more than one set of output Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Master File Guidelines

Master Files contain definitions for input and output parameters used in the transaction. These parameters are described as separate segments.

- A dummy segment must be defined if input parameters are not used.
- Output parameters (if they exist) are defined in a descendant segment/segments.
- Fields from output segments that contain repeating values can be redefined as an Occurs segment. A value for the keyword POSITION defines the redefined field name.
- A multi-segment definition with the RECTYPE field is used when a transaction may return different answer sets.

Example: Cobol Copybook for the ETPBRW8 Master File

```
02  FILEREC.
  03  STAT           PIC X.
  03  NUMB           PIC X(6).
  03  NAME           PIC X(20).
  03  ADDRX          PIC X(20).
  03  PHONE          PIC X(8).
  03  DATEX          PIC X(8).
  03  AMOUNT         PIC X(8).
  03  COMMENT        PIC X(9).
```

Example: Master File for the Transaction/Program

```
FILENAME=ETPBRW8, SUFFIX=CICSTRAN, CODEPAGE=37, $
  SEGMENT=SEG1, SEGTYPE=S0, $
   GROUP=FILEREC, USAGE=A80, ACTUAL=A80, $
    FIELDNAME=STAT, USAGE=A1, ACTUAL=A1, $
    FIELDNAME=NUMB, USAGE=A6, ACTUAL=A6, $
    FIELDNAME=NAME, USAGE=A20, ACTUAL=A20, $
    FIELDNAME=ADDRX, USAGE=A20, ACTUAL=A20, $

```

Reference: Access File Attributes

Keyword	Description
SEGNAME	Is the name of the input segment in the Master File.
CONNECTION	Indicates the connection_name as previously specified in a SET CONNECTION_ATTRIBUTES command. Defaults to the default connection.
TRANSACTION	Is the name of the program to be executed.

Keyword	Description
COMMAREA	Is the maximal size of COMMAREA for the Adapter for CICS Transactions. The options are: CALC means that the maximal segment length will be used. value defaults to 32500. You can enter a value that represents the physical length of the data.

Example: **Access File for Transaction/Program**

```
SEGNAME=SEG1,CONNECTION=CICST1,TRANSACTION=etpbrw8,COMMAREA=32500,
  FLOAT=IBM,INTEGER=BigEndian,$
```

Note: Do not change the FLOAT or INTEGER parameter values.

Example: **Sample CICS Transaction**

```

```

Invoking a CICS Transaction

To invoke a CICS transaction, you issue a Data Manipulation Language (DML) request, also known as a TABLE command, an SQL SELECT statement, or an EX command. (DML is Information Builders internal retrieval language.) For information about the Data Manipulation Language, see the *Stored Procedure Reference* manual.

Syntax: How to Invoke a CICS Transaction Using TABLE

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the CICS transaction you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

IF/WHERE

Is used if you want to pass values to input parameters.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

Syntax: How to Invoke a CICS Transaction Using SELECT

```
SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the CICS transaction you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

`WHERE`

Is used if you want to pass values to input parameters.

You must specify the value of each parameter on a separate line.

`in-parameter`

Is the name of an input parameter to which you want to pass a value.

`value`

Is the value you are passing to an input parameter.

Syntax: How to Invoke a CICS Transaction Using EX

```
EX [app_name_space/]synonym  1=parm1_val,..., N=parmN_val

EX [app_name_space/]synonym parm1_name=parm1_val,... ,
                            parmN_name=parmN_val

EX [app_name_space/]synonym [, parm1_val [,...[, parmN_val]]]
```

where:

`app_name_space`

Is the apps directory name under which the synonyms are stored. This value is optional.

`synonym`

Is the user friendly name of a repository entry that represents the object to be executed in the vendor environment.

`parm_name`

Is the name of the parameter taken from the input metadata description.

`1=parm1_val`

`N=parmN_val`

`parm1_name`

`parm1_val`

`parmN_val`

Are the parameter values that match the input metadata description.

Note:

- Consecutive commas denote missing parameters in the positional form of the request.

- Values containing special characters (<equal sign> <space> <comma>) must be encapsulated in double or single quotation marks.

Example: **Invoking the ETPBRW8 Transaction**

The following TABLE command invokes the ETPBRW8 transaction, passing one parameter value to it.

```
TABLE FILE ETPBRW8
  PRINT SEG11.NUMB SEG11.STAT SEG11.NAME SEG11.ADDRX SEG11.PHONE
  IF SEG1.NUMB EQ '000700'
END
```

The output is:

```
NUMBER OF RECORDS IN TABLE=        4  LINES=      4

PAGE     1

NUMB    STAT  NAME                 ADDRX                PHONE
----    ----  ----                 -----                -----
000762        SUSAN MALAIKA        SAN JOSE,CALIFORNIA  22312121
000983        J. S. TILLING        WASHINGTON, DC       34512120
001222        D.J.VOWLES           BOBLINGEN, GERMANY   70315551
001781        TINA J YOUNG         SINDELFINGEN,GERMANY 70319990
```

The following SELECT command invokes the ETPBRW8 transaction:

```
SQL
SELECT  SEG11.NUMB, SEG11.STAT, SEG11.NAME, SEG11.ADDRX, SEG11.PHONE
FROM ETPBRW8
WHERE SEG1.NUMB = '000700';
END
```

The output is:

```
PAGE     1

NUMBER OF RECORDS IN TABLE=        4  LINES=      4

NUMB    STAT  NAME                 ADDRX                PHONE
----    ----  ----                 -----                -----
000762        SUSAN MALAIKA        SAN JOSE,CALIFORNIA  22312121
000983        J. S. TILLING        WASHINGTON, DC       34512120
001222        D.J.VOWLES           BOBLINGEN, GERMANY   70315551
001781        TINA J YOUNG         SINDELFINGEN,GERMANY 70319990
```

The following EX commands invoke the ETPBRW8 transaction:

```
EX ETPBRW8 '000700'

EX ETPBRW8 NUMB='000700'

EX ETPBRW8 1='000700'
```

The ETPBRW8 transaction browses the file starting from '000700' and, in these examples, returns values greater than '000700'.

Note: In order to use the EX command, you must set the SET EXORDER setting in either the FOCEXEC or in edasprof.prf.

```
SET EXORDER=PGM/FEX

EX baseapp/etpbrw8 NUMB='000700'
```

The output is:

```
FILE=SQLOUT,SUFFIX=FIX,$
  SEGNAME=SQLOUT,$
    FIELD=STAT,    E11       ,A1       ,A1       ,          ,$
    FIELD=NUMB,    E12       ,A6       ,A6       ,          ,$
    FIELD=NAME,    E13       ,A20      ,A20      ,          ,$
    FIELD=ADDRX,   E14       ,A20      ,A20      ,          ,$
    FIELD=PHONE,   E15       ,A8       ,A8       ,          ,$
    FIELD=DATEX,   E16       ,A8       ,A8       ,          ,$
    FIELD=AMOUNT,  E17       ,A8       ,A8       ,          ,$
    FIELD=COMMENT, E18       ,A9       ,A9       ,          ,$

Running a TPG/SPG/AAS Transaction

You can use the Adapter for CICS Transactions to execute a CICS program developed for TP Gateway/Stored Procedures Gateway/Application Adapter Server (AAS).

See the *Server Release Notes* for information about migrating older TPG/SPG/AAS applications.

Chapter 16 Using the Adapter for Cloudera Impala to Access Data Managed by Hadoop

The Adapter for Cloudera Impala provides for analysis of both structured and complex data. Impala provides a JDBC driver and the Hive Query Language, a SQL-like interface with a real time query capability that shares the metadata layer and query language with Hive.

In this chapter:

Introducing the Adapter for Cloudera Impala

Hadoop is a collection of open source products and technologies administered by the Apache Software Foundation. CDH is Cloudera's Hadoop distribution. Cloudera Impala is an integrated part of CDH that provides an analytic database.

Cloudera Impala adds a real time query capability that shares the metadata layer and query language with Hive. It is available on CDH and other selected Hadoop distributions.

The Cloudera Impala adapter is JDBC based. The DataMigrator or WebFOCUS server can be run on any platform (including Windows) that connects to the server where Cloudera Impala is running.

Cloudera Impala can be accessed with either the Apache Hive JDBC driver or the Cloudera Impala JDBC driver.

Preparing the Cloudera Impala Environment

The following components are needed to use the adapter for Hadoop/Hive/Impala:

- **Java.** To use this JDBC-based adapter, you must have Java installed. Hadoop requires Version 1.7 or later. Java can be downloaded from *http://www.java.com*.

The location of Java must be specified in an environment variable.

If you are using Linux, add a line to your profile with the location where Java is installed. For example:

```
export JAVA_HOME=/usr/lib/jvm/jre-1.7.0
```

If you have JDK installed:

```
export JAVA_HOME=/usr/lib/jvm/jdk-1.7.0
```

If you are using Windows, right-click *Computer* and click *Properties*. Then click *Advanced System Settings* and click *Environment Variables*. Add the locations to your PATH variable. For example:

```
C:\Program Files\Java\jdk7\bin\server;C:\Program Files\Java\jdk7\bin;
```

- **JDBC Driver.** The JDBC driver requires a collection of jar files. If you are using the Apache Hive JDBC driver, they are included in CDH. If you are installing the server on the same system where Hive is installed, you can point to the jar files as described in the next section. If you are installing the server on some other system, copy those files to a location of your choice. If you are using the Cloudera Impala JDBC driver, download as described below.

Procedure: How to Configure the Java CLASSPATH

The location of the JDBC driver jar files must be specified to the server. If you are running the server on the same system as the Impala server, you can specify their location. If you are running the server on another system, copy the files listed below to a location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, click *Workspace*

   or

   From the Data Management Console, expand the *Workspace folder*.
2. Expand the *Java Services* folder. Right-click *DEFAULT* and click *Properties*.

   The Java Services Configuration page opens.
3. Click the chevrons to expand Class Path.

In the IBI_CLASSPATH box, enter the full location of the Hive and Hadoop files shown below, where *hive_home* is where Hive is installed and *hadoop_home* is where Hadoop is installed. You must type them explicitly and cannot use $HIVE_HOME. The file names must be entered one per line.

If you are installing the adapter on a different system than where Hadoop and Hive are installed, copy the jar files to a location on that system.

Note: For a server running on Windows, use Windows syntax for directory names. For example:

```
C:\jdbc\hive-jdbc-1.2.0-standalone.jar
```

For the Apache Hive JDBC Driver:

```
/hive_home/lib/hive-jdbc-standalone.jar
/hadoop_home/hadoop-common.jar
```

If your Hive server is Kerberos enabled, also add:

```
/hadoop_home/client/hadoop-auth.jar
```

For Cloudera Impala

Download the JDBC driver from Cloudera. Go to the Downloads page at *http://www.cloudera.com/downloads.html*.

Click the link for Impala JDBC Driver downloads. For your operating system, select your OS Version and click the Download Now link.

This will download a file called impala_jdbc_2.5.34.zip (the numbers will change with new releases). It contains two more .zip files. Unzip the file Cloudera_Impala_JDBC41_2.5.34.zip to a location on your system (the 41 in the name indicates JDBC 4.1, which supports Java 1.7 or later). These 15 jar files constitute the Cloudera Impala JDBC driver.

Add the names of all of them to your CLASSPATH or IBI_CLASSPATH as described above.

4. Scroll down and click the *Save and Restart Java Services* button.

Configuring the Adapter for Cloudera Impala

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Cloudera Impala Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. Right-click *Cloudera Impala* and click *Configure*.

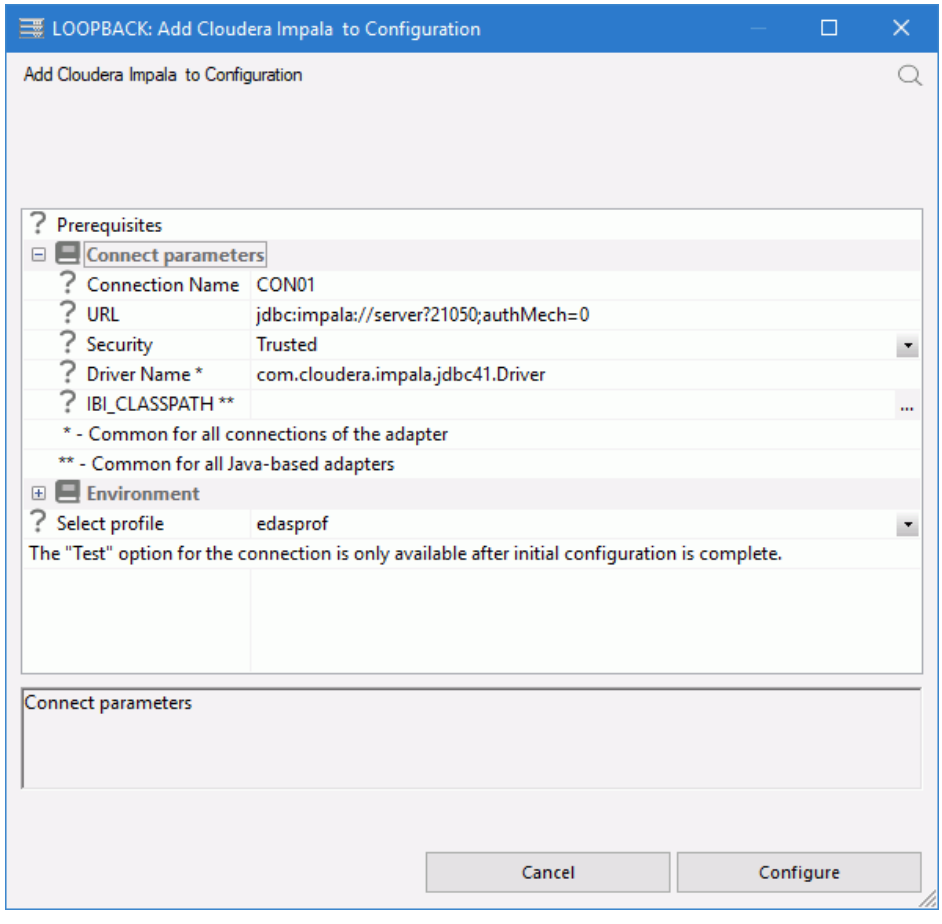
4. In the URL box, type the URL used to connect to your Hive or Impala server. For more information, see *Cloudera Impala Adapter Configuration Settings* on page 423.

5. In the Driver Name box, type the JDBC driver that you are using from the following table:

Adapter	JDBC Driver Name
Apache Hive	`org.apache.hive.jdbc.HiveDriver`
Cloudera Impala	`com.cloudera.impala.jdbc41.Driver`

6. Select the security type. If you are using Explicit, type your user ID and password.

The following image shows an example of the configuration settings used:



7. Select *edasprof* from the drop-down menu to add this connection for all users, or select a user profile.
8. Click *Test*. You should see a list of data sources on your server.
9. Click *Configure*.

Reference: Cloudera Impala Adapter Configuration Settings

The Adapter for Hadoop/Hive/Impala is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Is the URL to the location of the data source.

The URL used depends on which JDBC driver and which server you are connecting to.

JDBC Driver	Security	URL
Hive	None	`jdbc:hive2://server:21050/;auth=noSasl`
Hive	Kerberos (static)	`jdbc:hive2://server:21050/default; principal=impala/server@REALM.COM`
Hive	Kerberos (user)	`jdbc:hive2://server:21050/ default;principal=impala/server@REALM.COM; auth=kerberos;kerberosAuthType=fromSubject`
Impala	None	`jdbc:impala://server:21050;authMech=0`
Impala	User name and password	`jdbc:impala://server:21050; authMech=3,UID=user,PWD=pass`
Impala	Kerberos	`jdbc:impala://server:21050; AuthMech=1;KrbRealm=REALM.COM; KrbHostFQDN=server.example.com; KrbServiceName=impala`

where:

server

Is the DNS name or IP address of the system where the Hive or Impala server is running. If it is on the same system, localhost can be used.

`default`

Is the name of the default database to connect to.

`21050`

Is the default port number for an Impala server.

`auth=noSasl`

Indicates that there is no security on the Impala server.

REALM.COM

For a Kerberos enabled Impala server, this Is the name of your realm.

For further descriptions of the Impala JDBC driver options, see the *Cloudera JDBC Driver for Impala* manual.

Driver Name

Is the name of the JDBC driver, for example, org.apache.hive.jdbc.HiveDriver or com.cloudera.impala.jdbc41.Driver.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database at connection time for authentication.
- **Trusted.** The adapter connects to Impala as an operating system login using the credentials of the operating system user impersonated by the server data access agent.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and type a name in the Profile Name field (the extension is added automatically).

Kerberos

Connections to an Impala server with Kerberos enabled can be run in one of two ways:

- **Static credentials.** The same Kerberos credential is used for all connections. You must obtain a Kerberos ticket before starting the server.
- **User credentials.** Each user connecting to the server connects to Impala using credentials from the Impala Adapter connection in the server or user profile.

To set up connections to a Kerberos enabled Impala server:

1. The Reporting Server has to be secured. The server can be configured with security providers PTH, LDAP, DBMS, OPSYS, or Custom, as well as multiple security providers environment,
2. In addition to the jar files listed above, the following jar must be added to the CLASSPATH or IBI_CLASSPATH for the server:

   ```
   /hadoop_home/client/hadoop-auth.jar
   ```

Kerberos Static Requirements

In this configuration, all connections to the Impala server will be done with the same Kerberos user ID derived from the Kerberos ticket that is created before the server starts.

1. Create Kerberos ticket using:

   ```
   kinit kerbid01
   ```

   where:

   kerbid01

   Is a Kerberos ID.

2. Verify Kerberos ticket using *klist*. A message similar to the following should be returned:

```
Ticket cache: FILE:/tmp/krb5cc_532
Default  principal: kerbid01@REALM.COM

Valid Starting     Expires         Service principal
04/29/16 16:26:50  04/30/16 02:26:53  krbtgt/REALM.COM@REALM.COM
   renew until 05/06/16 16:26:50
```

3. Before configuring the Impala Adapter connection to a Kerberos enabled instance, the connection should be tested. Log in to the system running Hive and use Beeline, the native tool, to test it.
4. Start the server in the same Linux session where the Kerberos ticket was created. Log in to the Web Console and click the *Adapters* tab.
5. Right-click *Cloudera Impala* and click *Configure*. Use the following parameters to configure the adapter:

   URL

   Enter the URL. For the Apache Hive adapter, use:

   ```
   jdbc:hive2://server:21050/default;principal=hive/server@REALM.COM
   ```

   Security

   Set to *Trusted*.

6. In the Select profile drop-down menu, select the *edasprof* server profile.
7. Click *Configure*.
8. Next, configure Java services. Click the *Workspace* tab and expand the *Java Services* folder.
9. Right-click *DEFAULT* and click *Properties*.
10. Expand the *JVM Settings* section. In the JVM options box, add the following:

    ```
    -Djavax.security.auth.useSubjectCredsOnly=false
    ```

11. Restart Java services.

Once these steps are completed, the adapter can be used to access a Kerberos-enabled Hive instance.

Kerberos User Credentials Requirements

In this configuration, the connection from the server profile is used or each connected user has an Impala Adapter connection with Kerberos credentials in the user profile.

1. Enable multi-user connection processing for Kerberos by adding the following line to your profile (edasprof.prf):

   ```
   ENGINE SQLIMP SET ENABLE_KERBEROS ON
   ```

2. Configure the Impala Adapter Connection in the user profile using the following values:

   URL

   For the adapter for Apache Hive:

   ```
   jdbc:hive2://server:21050/default;principal=impala/server@REALM.COM;
   auth=kerberos;kerberosAuthType=fromSubject
   ```

   For the Cloudera Impala adapter:

   ```
   jdbc:impala://server:21050;AuthMech=1;KrbRealm=REALM.COM;
   KrbHostFQDN=server.realm.com;KrbServiceName=impala
   ```

   Security

   Set to *Explicit*

   User and Password

   Enter your Kerberos user ID and password. The server will use those credentials to create a Kerberos ticket and connect to a Kerberos-enabled Hive instance.

   Note: The user ID that you use to connect to the server does not have to be the same as the Kerberos ID you use to connect to a Kerberos enabled Hadoop cluster.

   Select Profile

   Select your profile or enter a new profile name consisting of the security provider, an underscore and the user ID. For example, *ldap01_pgmxxx*.

3. Click *Configure*.

Troubleshooting

If the server is unable to configure the connection, an error message is displayed. An example of the first line in the error message is shown below, where *nnnn* is the message number returned.

```
(FOC1400) SQLCODE IS -1 (HEX: FFFFFFFF) XOPEN: nnnn
```

Some common errors messages are:

```
[00000] JDBFOC>> connectx(): java.lang.UnsupportedClassVersionErr : or: org/
apache/hive/jdbc/HiveDriver : Unsupported major.minor version 51.0
```

The adapter requires Java 1.7 or later and your JAVA_HOME points to Java 1.6.

```
(FOC1500) ERROR: ncjInit failed. failed to connect to java server: JSS
(FOC1500) . JSCOM3 listener may be down - see edaprint.log for details
```

The server could not find Java. To see where it was looking, review the edaprint.log and set JAVA_HOME to the actual location. Finally, stop and restart your server.

```
(FOC1260)  (-1) [00000] JDBFOC>> connectx():
java.lang.ClassNotFoundException:
   org.apache.hive.jdbc.HiveDriver
(FOC1260) Check for correct JDBC driver name and environment variables.
(FOC1260) JDBC driver name is org.apache.hive.jdbc.HiveDriver
(FOC1263) THE CURRENT ENVIRONMENT VARIABLES FOR SUFFIX SQLIMP ARE :
(FOC1260) IBI_CLASSPATH : ...
 (FOC1260) CLASSPATH : C:\ibi\srv77\home\etc\flex\lib\xercesImpl.jar
```

The JDBC driver name specified cannot be found in the jar files specified in IBI_CLASSPATH or CLASSPATH. The names of the jar files are either not specified, or if specified, do not exist in that location.

```
[08S0] Could not establish connection to jdbc:hive2://hostname:21050/
auth=noSasl:
java.net.UnknownHostException: hostname
```

The server hostname could not be reached on the network. Check that the name is spelled correctly and that the system is running. Check that you can ping the server.

```
[08S01] Could not establish connection to server:21050/default:
: java.net.ConnectException: Connection refused
```

The Impala server is not listening on the specified port. Start the server if it is not running, and check that the port number is correct.

```
 (-1) [00000] JDBFOC>> makeConnection():
 javax.security.auth.login.LoginException: Pre-authentication
 information was invalid (24)
```

The Kerberos user ID and password combination is not valid.

Creating Synonyms With Cloudera Impala

Synonyms define unique names, or aliases, for each Hive table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Hive table.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Cloudera Impala

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Using Direct Pass-through With Cloudera Impala

Direct Pass-through commands, such as SHOW TABLES and DESCRIBE tablename, do not display any results.

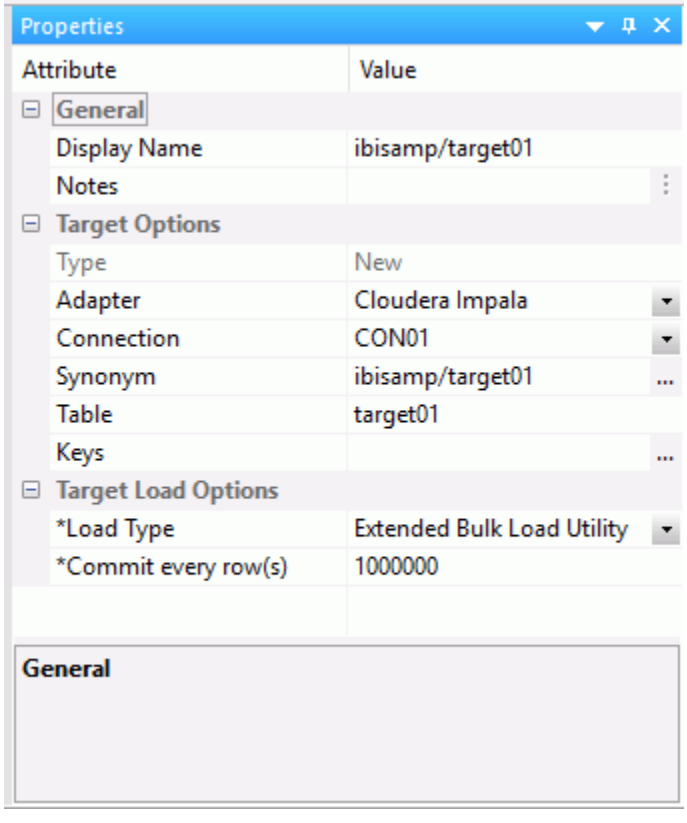
This can be avoided by adding a comment:

```
ENGINE SQLIMP
/*QUERY*/ SHOW TABLES ;
END
```

Loading Data Using DataMigrator

DataMigrator can be used to load data from any accessible data source into Hadoop and create metadata in Hive. Currently, the only load type supported is Extended Bulk Load.

To use DataMigrator to load data to Hadoop for access through Impala, we recommend that you install the DataMigrator Server on an Edge Node of your CDH cluster that has the Hadoop client software installed.If not, you can still use DataMigrator, but you must add the Fixed File adapter with the same name as the Impala adapter with an [S} FTP connection to a server where the Hadoop client is installed.



Chapter 17

Using the Adapters for C-ISAM and ISAM

The Adapters for AccuCobol C-ISAM, Informix C-ISAM, Micro Focus® C-ISAM, and FairCom c-tree ISAM allow applications to access C-ISAM and ISAM data sources. These adapters convert application requests into native C-ISAM/ISAM statements and return optimized answer sets to the requesting application.

You can also access compressed datasets with this adapter. However, the actual compression is done using the ZCOMP Exit. For details, see *Data Set Compression Exit: ZCOMP* on page 2719.

In this chapter:

Preparing the Informix C-ISAM Environment

For the Adapter for Informix C-ISAM on UNIX, no environment variable settings are required. However, if you are using the Adapter for Informix C-ISAM on Windows, you must add the location of the ISAM library called isamdll.dll (usually located in the CISAMDIR/bin directory) to the environment variable path.

For the Adapter for AccuCobol C-ISAM, you must add the location of the load libraries to the library path.

For the Adapter for Micro Focus C-ISAM, you must set and export a $COBDIR UNIX environment variable, which identifies the installation directory to the operating system.

For the Adapter for FairCom c-tree ISAM, you must add the location of the c-tree ISAM load libraries to the library path. (This adapter is only supported in the Solaris environment.)

Syntax: How to Identify the AccuCobol C-ISAM Load Library Files

```
LD_LIBRARY_PATH=path
export LD_LIBRARY_PATH
```

where:

path

Is the location of the AccuCobol C-ISAM load library files.

Note: If the server is running with security on, the IBIPATH variable needs to be used in place of LD_LIBRARY_PATH.

Syntax: How to Identify the Micro Focus C-ISAM Installation Directory

```
COBDIR=path
export COBDIR
```

where:

path

Is the location of the Micro Focus C-ISAM installation directory.

Syntax: How to Identify the FairCom c-tree ISAM Load Library Files

```
LD_LIBRARY_PATH=path
export LD_LIBRARY_PATH
```

where:

path

Is the location of the FairCom c-tree ISAM load library files.

Note: If the server is running with security on, the IBIPATH variable needs to be used in place of LD_LIBRARY_PATH.

Configuring the C-ISAM and ISAM Adapters

You can configure the adapters from the Web Console or the Data Management Console. In addition, for each type of file, you must specify the location of the data files you wish to access. You can define the location, either by:

- Including a FILEDEF command in a supported server profile. This approach enables you to quickly change the physical file name associated with the metadata.

- Specifying the location when you create a synonym. This approach enables you to define the data file location in the Master File.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Syntax: How to Specify the Location of an AccuCobol C-ISAM File

```
FILEDEF file_name DISK file_location
```

where:

file_name

Is the data file name.

file_location

Is the full path and file name of the data file, without the file extension.

Note:

- Read permissions must be given for the data file.
- For the Adapter for AccuCobol C-ISAM, read-only access is supported.

Syntax: How to Specify the Location of an Informix C-ISAM File

```
FILEDEF file_name DISK file_location
```

where:

file_name

Is the data file name.

file_location

Is the full path and file name of the data file. Omit the .dat extension.

Syntax: How to Specify the Location of a Micro Focus C-ISAM File

```
FILEDEF file_name DISK file_location
```

where:

file_name

Is the data file name.

file_location

Is the full path and file name of the data file.

Note:

- For each data file there must be a corresponding index file, except for Micro Focus compression 8 files, which do not have separate index files. The index is, instead, embedded in the data file.
- Read/write permissions must be given for both types of files.
- For the Informix Adapter for C-ISAM and the Micro Focus Adapter for C-ISAM, read and write access is supported.

Syntax: How to Specify the Location of a FairCom c-tree ISAM File

```
FILEDEF file_name DISK file_location
```

where:

file_name

Is the data file name.

file_location

Is the full path and file name of the data file, without the file extension.

Note:

- For each data file, there must be a corresponding index file and a corresponding parameter file.
- Read permissions must be given for all the above mentioned files.
- By default, the parameter file name is assumed to be the file_location followed by the ".p" extension.
- You can override the default parameter file name by specifying it in the environment variable EDACTPARMF.
- For the Adapter for FairCom c-tree ISAM, read-only access is supported.

Syntax: How to Specify the Location of a FairCom c-tree Parameter File

```
EDACTPARMF=path
export EDACTPARMF
```

where:

path

Is the location of the FairCom c-tree parameter file.

Note:

- By default, the parameter file name is assumed to be the file_location (as specified in a FILEDEF command or the DATASET attribute of a Master File), followed by the ".p" extension.
- You can override the default parameter file name by specifying it in the environment variable EDACTPARMF. This is required when selecting data from multiple ISAM files in a single query through a join. For such queries, a parameter file that describes all the tables involved must exist, and its name must be specified in EDACTPARMF.

Managing C-ISAM Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each C-ISAM file or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server's metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for AccuCobol C-ISAM, Informix C-ISAM, Micro Focus C-ISAM, and FairCom c-tree ISAM

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Collection of COBOL definitions

Directory path

Specify the path to the directory containing multiple COBOL files.

File name

File extension

If you wish to limit retrieval, you can enter a file name and/or file extension:

- In the File name box, enter a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.
- In the File extension box, enter an extension with or without the wildcard symbol %.

Location of data files

Directory path

Enter the path to the directory containing multiple data files.

File name

File extension

If you wish to limit retrieval, you can enter a file name and/or file extension:

- In the File name box, enter a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.
- In the File extension box, enter an extension with or without the wildcard symbol %.

  Note: Filtering data files based on file extensions is not supported in the Adapter for Informix C-ISAM.

Synonym field names processing options

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize options

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Choose Data file name

After choosing tables, choose the corresponding data file name from the drop-down list:

- For AccuCobol C-ISAM, Micro Focus CISAM and Faircom c-tree ISAM, choose the file name *without* an extension.
- For Informix C-ISAM, choose the file name with the extension.*idx*.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Maintaining C-ISAM Data Sources Using SQL Commands

The Adapters for Micro Focus C-ISAM and Informix C-ISAM support SQL INSERT, UPDATE, and DELETE operations against C-ISAM data sources. This facilitates development and implementation of new applications based on C-ISAM data sources.

While processing SQL transactions, you can issue the PASSRECS command to obtain counts of rows affected by each successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Syntax: How to Obtain the Number of Records Updated, Inserted or Deleted

```
ENGINE INT SET PASSRECS {ON|OFF}
```

where:

`INT`

Indicates that the PASSRECS setting in this command will be applied globally to all adapters that support SQL INSERT, UPDATE, and DELETE commands.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.

Using a Secondary Index in C-ISAM and ISAM Files

When a request contains search conditions for a field with a secondary index, the Adapters for C-ISAM and ISAM can access the secondary index directly, then retrieve the primary index value and use it to read the record. This process is much faster than reading an entire file sequentially and verifying each record against the search condition. It provides particular performance advantages when accessing large ISAM files, where secondary indexes are usually built on fields that are used in search conditions.

Example: Using a Secondary Index in a C-ISAM File

The C-ISAM file's secondary index field must be defined in the Master File with the attributes ALIAS=KEY*n* and FIELDTYPE=I.

The following Master File has a primary key field, EMPLOYEE_ID5, and four secondary indexes, SSN5, STATE_CODE5, CITIZENSHIP5 and DEPARTMENT5. These fields are defined with FIELDTYPE=I and the ALIAS names KEY1, KEY2, KEY3 and KEY4:

```
FILENAME=EMPLOYEE, SUFFIX=CISAM   ,
 DATASET=/qa/edamvt/CISAM/employee, $
  SEGMENT=SEG1, SEGTYPE=S0, $
  GROUP=G5, ALIAS=KEY, ELEMENTS=1, $
   FIELDNAME=EMPLOYEE_ID5, ALIAS=E3, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=SSN5, ALIAS=KEY1, USAGE=A11, ACTUAL=A11, FIELDTYPE=I,$
   FIELDNAME=FILLER, ALIAS=E5, USAGE=A1, ACTUAL=A1, $
   FIELDNAME=LAST_NAME5, ALIAS=E6, USAGE=A20, ACTUAL=A20, $
   FIELDNAME=FIRST_NAME5, ALIAS=E7, USAGE=A15, ACTUAL=A15, $
   FIELDNAME=FILLER, ALIAS=E8, USAGE=A1, ACTUAL=A1, $
   FIELDNAME=BIRTHDATE5, ALIAS=E9, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=SEX5, ALIAS=E10, USAGE=A1, ACTUAL=A1, $
   FIELDNAME=FILLER, ALIAS=E11, USAGE=A3, ACTUAL=A3, $
   FIELDNAME=ETHNIC_GROU5, ALIAS=E12, USAGE=A15, ACTUAL=A15, $
   FIELDNAME=FILLER, ALIAS=E13, USAGE=A1, ACTUAL=A1, $
   FIELDNAME=STREET5, ALIAS=E14, USAGE=A20, ACTUAL=A20, $
   FIELDNAME=CITY5, ALIAS=E15, USAGE=A15, ACTUAL=A15, $
   FIELDNAME=FILLER, ALIAS=E16, USAGE=A1, ACTUAL=A1, $

   FIELDNAME=STATE_CODE5, ALIAS=KEY2, USAGE=A2, ACTUAL=A2, FIELDTYPE=I, $
   FIELDNAME=FILLER, ALIAS=E18, USAGE=A2,ACTUAL=A2,$
   FIELDNAME=ZIP5, ALIAS=E19, USAGE=A5, ACTUAL=A5, $
   FIELDNAME=FILLER, ALIAS=E20, USAGE=A3, ACTUAL=A3, $
   FIELDNAME=HOME_PHONE5, ALIAS=E21, USAGE=A12, ACTUAL=A12, $
   FIELDNAME=WORK_PHONE5, ALIAS=E22, USAGE=A4, ACTUAL=A4, $
   FIELDNAME=CLEARANCE5, ALIAS=E23, USAGE=A2, ACTUAL=A2, $
   FIELDNAME=FILLER, ALIAS=E24, USAGE=A2, ACTUAL=A2, $
   FIELDNAME=START_DATE5, ALIAS=E25, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=SALARY5, ALIAS=E26, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=JOB_TITLE5, ALIAS=E27, USAGE=A24, ACTUAL=A24, $
   FIELDNAME=JOB_LEVEL5, ALIAS=E28, USAGE=I11, ACTUAL=I4, $
   FIELDNAME=SCHEDULE5, ALIAS=E29, USAGE=I11, ACTUAL=I4, $

   FIELDNAME=CITIZENSHIP5, ALIAS=KEY3, USAGE=A5, ACTUAL=A5, FIELDTYPE=I, $
   FIELDNAME=FILLER, ALIAS=E31, USAGE=A3, ACTUAL=A3, $
   FIELDNAME=SUPERVISOR5, ALIAS=E32, USAGE=P15.0, ACTUAL=P8, $

   FIELDNAME=DEPARTMENT5, ALIAS=KEY4, USAGE=I11, ACTUAL=I4, FIELDTYPE=I,  $
   FIELDNAME=DISABILITY5, ALIAS=E34, USAGE=A1, ACTUAL=A1, $
   FIELDNAME=FILLER, ALIAS=E35, USAGE=A3, ACTUAL=A3, $
```

To process the following request,

```
TABLE FILE EMPLOYEE
PRINT EMPLOYEE_ID5 SSN5 LAST_NAME5 IF STATE_CODE5 EQ 'IL'
END
```

the adapter uses STATE_CODE5 in a secondary index search. The C-ISAM table is accessed using the E (EQ) option on the secondary key. If more than one record has the same value for the secondary key, the adapter performs a sequential read (S) on the secondary index until all values of the secondary key are retrieved.

Chapter 18

Using the Adapter for DATACOM

The Adapter for CA-DATACOM/DB allows applications to access DATACOM data sources. The adapter converts application requests into native DATACOM statements and returns optimized answer sets to the requesting application.

Note: Throughout this topic, CA-DATACOM/DB is referred to as DATACOM.

In this chapter:

Preparing the DATACOM Environment

The Adapter for CA-DATACOM/DB operates in the z/OS and USS environments and issues standard DATACOM calls for record retrieval. The adapter uses DATACOM Boolean selection capabilities, enabling it to retrieve only records that satisfy a request. This reduces the number of I/Os involved in data retrieval.

Prior to configuring the Adapter for DATACOM/DB using the Web Console, you must edit the ISTART JCL that is used to initiate the server by allocating the DATACOM.CAILIB and DATACOM.CUSLIB libraries to the server STEPLIB.

Note: If user requirement tables (URTs) are kept in a library other than CUSLIB, you may need to add an additional library to STEPLIB. For details about URTs, see *Controlling Data Access With a User Requirements Table* on page 459.

As part of your environment preparation, you must also create the AUTOURT User Table that is required to create a synonym.

Creating the AUTOURT User Table

A User Requirements Table contains all the tables that an application can access. This is the DATACOM table that is used to create a synonym. For the DATACOM data dictionary, the table is called AUTOURT. You must use the jcl that is shipped with the product to create AUTOURT.

An example of JCL that creates a AUTOURT is located in HOME.DATA in the member GENAUTO1 and GENAUTO2. For your convenience, the sample code is provided in this documentation.

Example: Sample JCL for GENAUTO1 and GENAUTO2

Run GENAUTO1 followed by GENAUTO2:

- GENAUTO1 creates the required tables and creates AUTOURT1.
- GENAUTO2 calls the intermediate file AUTOURT1 and creates the User Requirements Table, AUTOURT, which is required when you create a synonym for a DATACOM data source.

```
//GENAUTO1 JOB 'PROG',MSGCLASS=X,CLASS=S

//*************************************************************
//* NAME:     GENAUTO1
//*
//* FUNCTION: STEP1 IN CREATING DATADICTIONARY URT
//*           NEEDED FOR OUR DATACOM ADAPTER TO CREATE SYNONYMS.
//*           DO NOT CHANGE ANY OF THE ENTRIES FOR THE DBURTBL
//* SUBSTITUTIONS:-CHANGE "DATACOM.CAIMAC" TO THE NAME OF YOUR
//*                 DATACOM MACRO LIBRARY.
//*                -CHANGE  SYSLMOD TO LIBRARY WHERE YOU ARE GOING
//*                 KEEP URTS.
//*************************************************************

Configuring the Adapter for DATACOM

You configure the Adapter for DATACOM from the Web Console.

Users accessing the DATACOM DBMS are authenticated by the Operating System security package, as well as any authentication performed by the DBMS itself.

Note: The Adapter for DATACOM uses the connection attributes declaration only for synonym creation purposes.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for DATACOM

The *DATACOM* adapter is under the *DBMS* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection Name

Is the logical name used to identify this particular set of attributes.

You can establish multiple connections to a Datacom data source. However, the first connection_name must define the DBID of the Datacom data dictionary, which is required as the source for Create Synonym processing.

DBID

Database ID.

For the first connection, you must specify the Data Dictionary ID.

User Table

A User Requirements Table contains all tables that an application can access. Enter a valid User Table name for access to the Datacom database with the current DBID.

For the Datacom data dictionary, this is AUTOURT.

Note that sample JCL is shipped with the product for your use in preparing the DATACOM Environment. This JCL generates the User Requirements Table, AUTOURT.

Trace

Select from the drop-down list:

CBS

Sets the accumulation of Compound Boolean Selection (CBS) diagnostics to the DATACOM diagnostics file (PXX) by making "$$$" the first 3 bytes of the User Information Block for each Datacom command.

NO

Indicates no trace. NO is the default value.

The parameter is optional.

Skipselect

Select from the drop-down list:

NO

Provides access to the root segment as stipulated in the request. This value is the default.

YES

Provides sequential access to the root segment in the Access File even if logical criteria exist for the segment.

However, if a join connection has been defined to the root segment, a selection command is used.

The parameter is optional.

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down list and enter a name in the Profile Name input box. (The extension is added automatically).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE DATACOM SET CONNECTION_ATTRIBUTES connection_name /, ;
dbid: "USERTABLE urt_name [TRACE {CBS|NO}] [SKIPSELECT {YES|NO}]"
```

where:

connection_name

Is the logical name used to identify as particular set of attributes.

The connection_name that defines the DBID of the DATACOM data dictionary must be used as the source for Create Synonym processing.

dbid

Database ID.

For the first connection, you must specify the Data Dictionary ID.

urt_name

A User Requirements Table contains all tables that an application can access. Enter a valid User Table name for access to the DATACOM database with the current DBID. For related information, see *Controlling Data Access With a User Requirements Table* on page 459.

TRACE

Valid values are:

CBS sets the accumulation of Compound Boolean Selection (CBS) diagnostics to the DATACOM diagnostics file (PXX) by making "$$$" the first 3 bytes of the User Information Block for each DATACOM command.

NO indicates no trace. NO is the default value.

The parameter is optional.

SKIPSELECT

Valid values are:

NO

provides access to the root segment as stipulated in the request. This value is the default.

YES provides sequential access to the root segment in the Access File even if logical criteria exist for the segment.

However, if a join connection has been defined to the root segment, a selection command is used.

The parameter is optional.

Example: **Sample Attribute Declaration**

```
ENGINE DATACOM SET CONNECTION_ATTRIBUTES DATC /,;2: "USERTABLE AUTOURT"
ENGINE DATACOM SET CONNECTION_ATTRIBUTES ALX /,;905: "USERTABLE ALXURT"
```

Declaring Connection Attributes

Using the Default Connection

The Adapter for DATACOM uses the default connection name if the USERTABLE keyword is omitted from the Access File on the file level and the CONNECTION keyword is omitted on the segment level. For related information, see *Access Files for DATACOM* on page 475.

Syntax: How to Use the Default Connection

```
ENGINE DATACOM SET DEFAULT_CONNECTION [connection_name]
```

where:

`DATACOM`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection_name`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command.

Example: Using the Default Connection

The following SET DEFAULT_CONNECTION command selects the DATACOM database server named CON01 as the default server:

```
ENGINE DATACOM SET DEFAULT_CONNECTION CON01
```

Controlling Data Access With a User Requirements Table

First-level access to DATACOM data sources and fields is controlled by the DATACOM User Requirements Table (URT). DATACOM uses the URT to provide file and database-level security, and password protection for element-level security. The URT used for the server structure must include all the DATACOM database IDs contained in the Access File. At run time, the adapter dynamically loads the URT's load module.

The DATACOM Data Driver (like any other DATACOM application) uses a DATACOM User Requirements Table to access the appropriate DATACOM tables. A User Requirements Table contains all tables that an application can access.

One DATACOM URT containing many DATACOM tables can be described by one or many Master Files. The Access File contains the name of URT that dynamically calls the DATACOM URT.

An example of JCL that creates a DATACOM URT is located in HOME.DATA in the member GENURT1 and GENURT2. For your convenience, the sample code is provided in this documentation.

Note: To ensure the most efficient loading of URT tables, you can specify connection pooled deployment in the edaserve.cfg file from the *Workspace*, *Configuration*, *Data Services* option on the Web Console. For details, see *Configuring Deployment Modes* in *Running and Monitoring Your Server*.

Example: Sample JCL for User Requirements Table (GENURT1 and GENURT2)

Run GENURT1 followed by GENURT2.

```
//GENURT1 JOB 'PROG',MSGCLASS=X,CLASS=S
//*************************************************************

DATACOM Overview and Mapping Considerations

DATACOM is a flat file database management system. The DATACOM DATA DICTIONARY stores and manages descriptive data about a data source.

To access DATACOM data sources, you describe them to server, using server terminology and attributes. The descriptions are kept in a Master File and an associated Access File.

The Master File tells the server how to interpret the DATACOM data structure. It identifies the DATACOM:

- Elements
- Fields (for each of those elements)
- Field type and field length (as DATACOM stores them)

The Access File creates a bridge between the server and DATACOM. It translates server terminology into DATACOM syntax by identifying the appropriate DATACOM:

- Database IDs.
- 2-dimensional Tables in which all DATACOM data is stored.
- Native key fields that dictate the physical sequence in which the data is stored.
- Element security information that is used if an element is defined to DATACOM with a security code.

When the server receives a request, it:

- Looks for the Master File describing that data source.
- Finds the suffix DATACOM in the Master File. This tells the server the requested data is in a DATACOM data source.
- Loads the Adapter for DATACOM module. The adapter module then opens the Access File, in which it finds the DATACOM User Requirements Table (URT) name, the database ID(s), and file name(s).

The Adapter for DATACOM opens the URT and builds calls to DATACOM. The adapter retrieves the data and passes it to the server. The server then creates the answer set.

For details on describing data sources to a server and on Master Files and Access Files, and examples of DATACOM logical files, fields, and elements, see *Mapping Structures in the Server* on page 464.

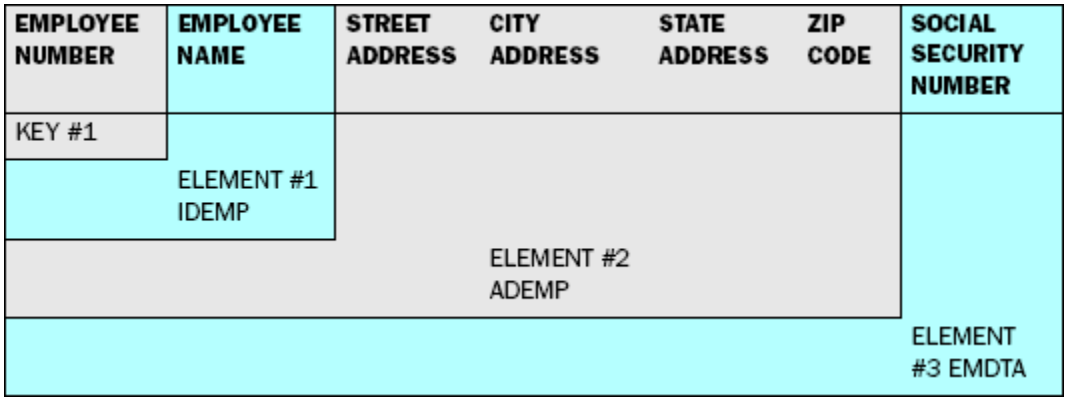
Data Structures

A DATACOM structure is a collection of one or more logical data sources, identified by a unique ID number. Each logical data source contains data records with a defined set of fields, elements, and keys, and is identified by a unique, alphanumeric 3-byte table name.

A data record consists of one or more elements. An element is the smallest logical unit of data a program can request; it has a unique 5-byte name. Elements consist of one or more contiguous fields and may have an associated security code. Because a field may belong to more than one element, the elements themselves may overlap.

DATACOM locates records through keys. Each data source may have up to 999 keys (not necessarily contiguous) consisting of 1-180 fields which total a length of 180 bytes. Each key is identified by a 5-byte name and a 3-byte numeric ID. The use of keys in the DATACOM Compound Boolean Selection Facility is transparent to the user.

The table below is the structure of the sample PERSON data source. It contains one key, three elements with fields that overlap, and seven unique fields.



Note: The DATACOM DATA DICTIONARY listing of the PERSON data source does not identify the specific fields in each element. For more information, refer to the DATA DICTIONARY Element Field Report.

The Employee Record Element (EMDTA) contains all seven fields in the data source.

The Employee Address Element (ADEMP) contains six fields that represent the employee ID and address. These are:

```
NUMBER
NAME
STREET_ADDRESS
CITY_ADDRESS
STATE_ADDRESS
ZIP_CODE_LOC
```

The Employee Identification Element (IDEMP) contains the NUMBER and NAME fields. All fields within each element are contiguous.

Mapping Structures in the Server

DATACOM terms equate to server terms as follows:

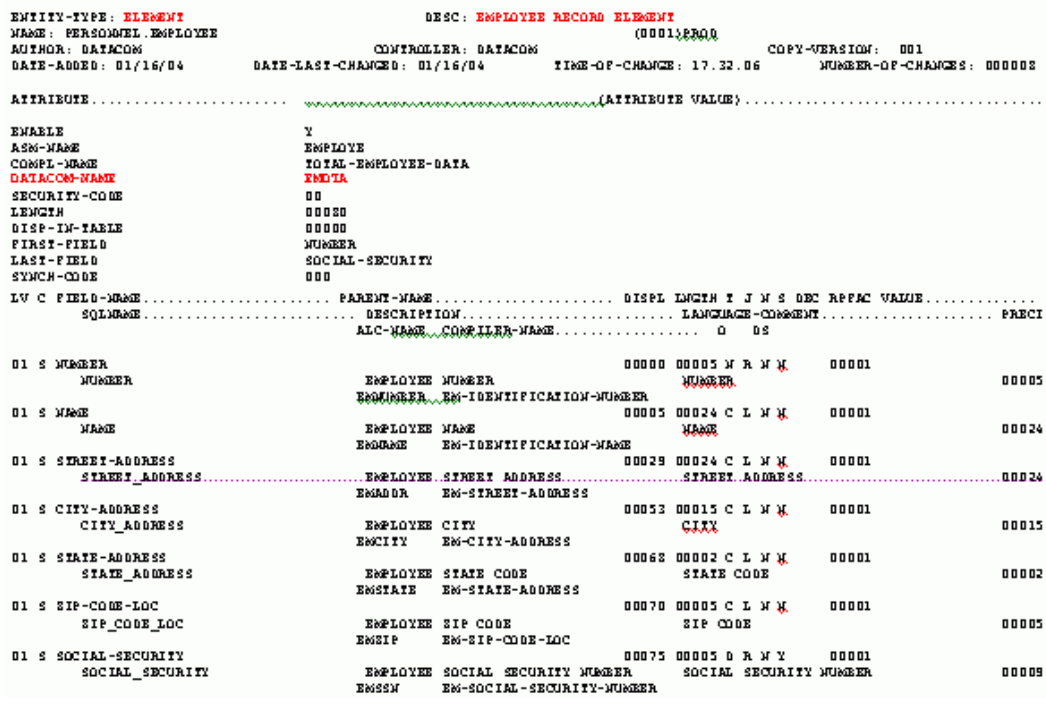
DATACOM Master File Definition	Server Master File Attributes
File	SEGMENT
Element	ALIAS for groups of fields
Field	FIELD
Field Length (LNGTH)	ACTUAL (DATACOM Format)USAGE (Server Format)

When you describe a DATACOM data source in a Master File:

- You can choose one or more elements from a DATACOM data source to build a single server segment. You do not have to specify all the elements in a particular data source.
- You must define *all fields* in the element, in the order in which they appears in the DATACOM data source. A DATACOM field becomes a server field.
- You can define two or more DATACOM elements that contain overlapping fields. However, you must define each overlapping field to the server with a unique name each time it appears in an element.
- Each DATACOM field you define to the server must have the 5-byte element name to which the DATACOM field belongs, together with a unique qualifier.
- For each DATACOM field, the DATACOM field length becomes the ACTUAL field length.
- The number of decimal positions that DATACOM indicates becomes the number of decimal positions in the USAGE format.

Example: Sample DATA DICTIONARY Element Field Report

The following example represents the DATA DICTIONARY Element Field Report for the Employee Record Element from the PERSON data source. For related information, see *Employee Record Element From PERSON Data Source* on page 465. For an explanation of the column headings in the report, see *Element Field Report Headings* on page 466.



```
ENTITY-TYPE: ELEMENT                          DESC: EMPLOYEE RECORD ELEMENT
NAME: PERSONNEL.EMPLOYEE                                    (0001)PROD

                                    EMCITY    EM-CITY-ADDRESS
01 S STATE-ADDRESS                                                   00068 00002 C L M M     00001
       STATE_ADDRESS                EMPLOYEE STATE CODE                  STATE CODE                      00002
                                    EMSTATE   EM-STATE-ADDRESS
01 S ZIP-CODE-LOC                                                    00070 00005 C L M M     00001
       ZIP_CODE_LOC                 EMPLOYEE ZIP CODE                    ZIP CODE                        00005
                                    EMZIP     EM-ZIP-CODE-LOC
01 S SOCIAL-SECURITY                                                 00075 00005 D R M Y     00001
       SOCIAL_SECURITY              EMPLOYEE SOCIAL SECURITY NUMBER      SOCIAL SECURITY NUMBER          00009
                                    EMSSN     EM-SOCIAL-SECURITY-NUMBER
```

Example: Employee Record Element From PERSON Data Source

The following Master File and Access File describe the Employee Record Element from the DATACOM PERSON data source.

Master File PERSON

```
FILENAME=PERSON, SUFFIX=DATACOM , $
  SEGMENT=PERSON, SEGTYPE=S0, $
    FIELDNAME=NUMBER,          ALIAS=EMDTA.0000, USAGE=P5,  ACTUAL=Z5,  $
    FIELDNAME=NAME,            ALIAS=EMDTA.0001, USAGE=A24, ACTUAL=A24, $
    FIELDNAME=STREET_ADDRESS,  ALIAS=EMDTA.0002, USAGE=A24, ACTUAL=A24, $
    FIELDNAME=CITY_ADDRESS,    ALIAS=EMDTA.0003, USAGE=A15, ACTUAL=A15, $
    FIELDNAME=STATE_ADDRESS,   ALIAS=EMDTA.0004, USAGE=A2,  ACTUAL=A2,  $
    FIELDNAME=ZIP_CODE_LOC,    ALIAS=EMDTA.0005, USAGE=A5,  ACTUAL=A5,  $
    FIELDNAME=SOCIAL_SECURITY, ALIAS=EMDTA.0006, USAGE=P10, ACTUAL=P5,  $
```

Access File PERSON

```
USERTABLE=SAMPURT, TRACE=NO, $
 SEGNAME= PERSON, TABLENAME=PMF, DBID=1, KEYNAME=EMPNO, $
  FIELD=NUMBER, SIGN=N, TYPE=C, $
  FIELD=SOCIAL_SECURITY, SIGN=Y, TYPE=C, $
```

Reference: Element Field Report Headings

Column Heading	Definition
LV (LEVEL)	The two-digit field level number.
C (CLASS)	Code representing the field class. Codes for the valid classes are: C = Compound (or parent) field F = Filler field I = Index S = Simple field V = Value (or qualifier) field
FIELD-NAME	Data dictionary occurrence name of the field.
PARENT-NAME (RECORD-NAME)	Data dictionary occurrence name of the parent field. Applies to compound fields only.
DISPL(DISP-IN-TABLE)	Displacement of the field in the record or table.
LNGTH (LENGTH)	Length of the field in bytes. For fields defined with a V data type (VARCHAR), this value includes the automatically generated two-byte field that defines the data's length.

Column Heading	Definition
T (TYPE)	Code representing the data type of the field. Codes for the valid data types are: B = Binary C = Character D = Packed decimal E = Extended-precision floating-point G = Graphics character set H = Hexadecimal with 2 characters per entry K = Kanji L = Long-precision floating-point N = Numeric field zoned decimal S = Short-precision floating-point T = PL/1 bit representation V = Variable length character Y = Pure DBCS Double-Byte Character Set Z = Mixed DBCS and EBCDIC 2 = Halfword binary 4 = Fullword binary 8 = Double word binary
J (JUSTIFICATION)	Justification: L = Left-justified R = Right-justified
N (NULL-INDICATOR)	Null indicator: N = No null-indicator, a one-byte indicator preceding this field. Y = Null indicator is present.
S (SIGN)	Sign: Y = Signed N = No sign
DEC (DECIMALS)	Decimal places for numeric, packed decimal, and binary fields.
RPFAC (REPEAT)	Repetition factor.

Column Heading	Definition
VALUE	Value attribute. This is either the default value of the field or the value associated with a qualified (CLASS=V) field.
DESCRIPTION	FIELD entity-occurrence description.
PRECISION	Specifies the maximum number of displayable digits allowed for data stored in fields. Available TYPEs are: D = Decimal N = Numeric G = Graphic V = Varchar W = Vargraphic

Managing DATACOM Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the DATACOM data types.

For the Adapter for DATACOM to access DATACOM files, you must describe each file you use in a Master and Access File. The logical description of an DATACOM file is stored in a Master File, which describes the field layout. The physical attributes of the DATACOM file, such as the database number and security are stored in the Access File.

Creating Synonyms

Synonyms define unique names (or aliases) for each DATACOM table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File, which represent the server's metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for DATACOM

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Filter Data Base Name

The first Create Synonym pane displays the connection name, user table, and data dictionary ID that were supplied during configuration. To see all related databases, simply click *Next*.

If you wish to filter the list of available databases, click the *Filter Data Base* check box. A Name input box is added to the pane.

Type a string for filtering the list of databases, inserting the wildcard character (%) as needed at the beginning and/or end of the string, then click *Next*.

For example, enter: ABC% to select all databases whose names begin with the letters ABC; %ABC to select databases whose names end with the letters ABC; %ABC% to select databases whose names contain the letters ABC at the beginning, middle, or end.

Data Base Name

On the second Create Synonym pane, select a database from the drop-down list and click *Next*.

Filter Table Name

If you wish to filter the list of available tables, click the *Filter Table Name* check box. A Name input box is added to the pane.

Type a string for filtering the list of tables, inserting the wildcard character (%) as needed at the beginning and/or end of the string, then click *Next*.

Table Name

On the third Create Synonym pane, select a table in the selected database from the drop-down list and click *Next*.

URT or Connection

On the final Create Synonym pane, indicate whether you want to generate the synonym with a user requirements table (URT) or a connection name. The generated *Access File Attributes* on page 480 depend on the method you choose here. (For an illustration of the differences, see *Access Files Generated by URT and Connection* on page 485.)

If you choose URT, enter the name of a user requirements table. This table defines the database and files that a user can access.

Note that this entry is not required for creating a synonym, however, data cannot be accessed without it. For more information about the user requirements table, see *Controlling Data Access With a User Requirements Table* on page 459.

If you choose Connection, enter the name of the connection that defines the URT and Database ID for accessing Datacom data.

Synonym name

Displays the name that will be assigned to the synonyms. To assign a different name, replace the displayed value.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Select elements

An element is the smallest unit of data. An element contains fields that can belong to more than one element.

- To select all elements in the list, select the check box to the left of the *Element Name* column heading.
- To select specific elements, select the corresponding check boxes.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Master Files for DATACOM

There are three types of Master File declarations.

Each declaration must begin on a separate line. A declaration consists of attribute-value pairs separated by commas. A declaration can span as many lines as necessary, as long as no single keyword-value pair spans two lines.

Do not use system or reserved words as names for files, segments, fields, or aliases. Specifying a reserved word generates syntax errors.

File Attributes

Each Master File begins with a file declaration. The file declaration has two attributes, FILENAME and SUFFIX

```
FILE[NAME]=filename, SUFFIX=DATACOM [,$]
```

where:

filename

Identifies the Master File. The file name can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents.

DATACOM

Is the value for the Adapter for CA-DATACOM/DB.

Segment Attributes

Each table described in a Master File requires a segment declaration. The segment declaration consists of at least two attributes, SEGNAME and SEGTYPE

```
SEGNAME=segname, SEGTYPE=type [,$]
```

where:

segname

Is the segment name that serves as a link to the actual DATACOM table name. It can consist of a maximum of 8 alphanumeric characters. It may be the same as the name chosen for FILENAME, the actual table name, or an arbitrary name.

The SEGNAME value in the Master File must be identical to the SEGNAME value specified in the Access File.

type

Indicates the type of segment sequencing:

SO indicates the segments are logically sequenced in low-to-high order.

U indicates a unique segment.

Field Attributes

Each row in a table may consist of one or more columns. These columns are described in the Master File as fields with the following primary field attributes:

FIELDNAME

Identifies the name of a field.

ALIAS

Identifies the DATACOM 5-byte element short name to which the field belongs, along with a unique qualifier.

USAGE

Identifies how to display a field on reports.

ACTUAL

Identifies the datatype and length in bytes for a field.

You can get values for these attributes from the DATACOM DATA DICTIONARY Element Field Report.

The syntax for a field declaration is

```
FIELD[NAME]=fieldname, ALIAS=elementname.qualifier,
 [USAGE=]display_format, [ACTUAL=]storage_format ,$
```

where:

fieldname

Is the unqualified name of the field. You must describe the fields in the order in which they appear in the DATACOM element. You can find the DATACOM field names, their relative position within the element, and the DATACOM formats in the DATA DICTIONARY Element Field Report. This value must be unique within the Master File. The name can consist of a maximum of 66 alphanumeric characters. The name must begin with a letter. Special characters and embedded blanks are not recommended.

Note that some elements contain overlapping fields. You must define overlapping fields for those elements in which they appear, and assign a unique field name each time.

Note: You must describe all the columns of the DATACOM element in your Master File. However, if there is a column(s) you do not need, you can supply filler information as a placeholder.

elementname

Is the DATACOM 5-byte element short name, followed by a period, to which the field belongs. You can find the name in the DATACOM DATA DICTIONARY listing of Master Files.

qualifier

Is the qualifier that is separated from the element name by a period. The qualifier is used to make the ALIAS unique and provide the field with an alternate identification. The total length of the ALIAS, including the element name and qualifier, cannot exceed 12 characters.

display_format

Is the display format. The value must include the field type and length and may contain edit options.

The data type of the display format must be identical to that of the ACTUAL format. For example, a field with an alphanumeric USAGE data type must have an alphanumeric ACTUAL data type.

Fields or columns with decimal or floating point data types must be described with the correct scale (s) and precision (p). Scale is the number of positions to the right of the decimal point. Precision is the total length of the field.

For the server, the total display length of the field or column *includes* the decimal point and negative sign. In SQL, the total length of the field or column *excludes* the decimal point and negative sign.

For example, a column defined as DECIMAL(5,2) would have a USAGE attribute of P7.2 to allow for the decimal point and a possible negative sign.

For related information, see *USAGE Conversion Formats From DATACOM* on page 475.

storage_format

Is the storage format of the DATACOM data type and length, in bytes, for the field. You can find this under LNGTH in the field report.

Reference: **USAGE Conversion Formats From DATACOM**

The following table provides information about conversion formats for DATACOM data types.

DATACOM Type	DATACOM Length	USAGE Type	USAGE Length
C (Character)	*n*	A (Alphanumeric)	*n*
N (Numeric; Zoned decimal)		P (Packed decimal)	*n* +1 (if decimal) +1 (if sign space)
D (Packed Decimal)	*n*	P (Packed decimal)	(2**n*)-1 (+ 1 if decimal) +1 (if sign space)
B (Binary)	2	I (Integer)	4
	4	I (Integer)	10

where:

n

Is the DATACOM length (LNGTH) of the fields.

Access Files for DATACOM

Each Master File must have a corresponding Access File. The file name of the Access File must be the same as that used for the Master File.

The Access File serves as a link between the server and DATACOM. It stores such information as the URT name, DATACOM Database ID(s), DATACOM table name(s), keyname(s), and element security information. In addition, the Access File provides you with the TRACE parameter, a useful debugging tool.

The Access File contains four types of logical records:

- Header record
- Segment record
- Element record
- Field record

Each consists of a list of keyword and value pairs, separated by commas and terminated by a comma and dollar sign (,$). The list is free-form and may span several lines; keywords may be in any order.

Syntax: How to Use the Header Logical Record

The header record contains these attributes

```
[USERTABLE=urt_name
 [,TRACE={NO|CBS}]
 [,SEQACCESS=[NO|YES}]
 [,FOUNDIMIT=nnnnnn]
 [,REJECTLIMIT=nnnnnn]
,$]
```

where:

urt_name

Is the name of the load module that supplies the DATACOM User Requirements Table (URT) information to be dynamically loaded. The URT must contain all the database IDs and file specified in the Master File, or you will not have access to the records.

This attribute is generated when you create a synonym based in a specified URT.

TRACE

NO indicates no trace. NO is the default value.

CBS sets the accumulation of Compound Boolean Selection (CBS) diagnostics to PXX by making "$$$" the first 3 bytes of the User Information Block for each Datacom command.

This attribute is generated when you create a synonym based on the specified URT.

SEQACCESS

NO provides access to the root segment as stipulated in the request. This value is the default.

Note: While SEQACCESS is a valid keyword, it is supported for backward compatibility and must be added to the Access File *manually*. You can perform the same function in the connection string using the SKIPSELECT option.

YES provides sequential access to the root segment in the Access File even if logical criteria exist for the segment.

However, if a join connection has been defined to the root segment, a selection command is used.

FOUNDLIMIT/REJECTLIMIT

Enable you to set interrupt limits to monitor the process of record selection. Accepted (Found) or Rejected records are physical records that either satisfy or do not satisfy the provided search values for non-indexed fields.

nnnnnn

Is the number of Interrupt Records rejected or accepted (found). When this number is reached, selection terminates. This value is applied for *all segments* of the Access File.

If required, you can add these attributes to the Access File manually.

Syntax: How to Use the Segment Logical Record

The segment record contains these attributes

```
SEGNAME=segname
 ,{DBID=dbid|CONNECTION=connection_name}
 ,TABLENAME=tablename
 ,KEYNAME=keyname
[,KEYFLD=keyfld, IXFLD=ixfld,]
[,FOUNDLIMIT=nnnnnn]
[,REJECTLIMIT=nnnnnn]
,$
```

where:

segname

Identifies the segment name. The Master File SEGMENT attribute is the same as the SEGNAME attribute in the Access File.

dbid

Identifies the numeric DATACOM database ID.

This attribute is generated when you create a synonym based on a specified URT.

connection_name

May be used in the Access file on the segment level. The value of this keyword is the valid connection _name that was previously set by the SET CONNECTION_ATTRIBUTES command.

Connection is used in the Access File only when the file level keyword USERTABLE is omitted. Otherwise, connection information is ignored.

Values for the keywords USERTABLE, DBID, TRACE, and SEQACCESS (or SKIPSELECT) are taken from the connection string and used for the current segment only.

This attribute is generated when you create a synonym based on a specified connection.

tablename

Identifies the 3-byte DATACOM table name to which the segment identified by SEGNAME corresponds. You can find this name in the DATA DICTIONARY Element Field Report, under DBNAME.

keyname

Is the 5-character alphanumeric name of the key being used in sequential access commands (GSETL/GETIT). The key name is defined in the Data dictionary KEY entity-occurrence field DATACOM-NAME.

For fastest sequential retrieval, specify the Native Key, which is in the DATA DICTIONARY Indented Report, where MN stands for mandatory native. If the KEYNAME value is not provided, records are processed in the physical sequence using the GSETP/GETPS commands. If a key other than the Native Key is specified, the data is internally requested. (Note that Random retrieval is slower than sequential retrieval.)

Note: KEYNAME does not have to be the native key. If you wish to use a different keyname, that is acceptable. However, be aware that you may not get all the records.

keyfld

Is the server field name from the parent segment of a cross-reference; it is mandatory for everything but the root segment. You may also specify multiple field names, concatenated with the forward slash symbol (/) without blanks. The keyword value must be contiguous, and on the same line. The key list can span multiple lines.

If required, you can add this attribute to the Access File *manually*.

ixfld

Is the server field name in the cross-referenced segment that establishes the cross-reference. It is mandatory for all but the root segment. The value(s) of these field(s) must have USAGE and ACTUAL formats comparable to the KEYFLD.

You may also specify multiple field names, concatenated with the forward slash symbol (/) without blanks. The keyword value may not span more than one line. The key list can span multiple lines.

If required, you can add this attribute to the Access File *manually*.

`FOUNDLIMIT/REJECTLIMIT`

Enable you to set interrupt limits to monitor the process of record selection. Accepted (Found) or Rejected records are physical records that either satisfy or do not satisfy the provided search values for non-indexed fields.

nnnnnn

Is the number of Interrupt Records rejected or accepted (found). When this number is reached, selection terminates. This value is applied *only to the designated segment*.

If required, you can add these attributes to the Access File manually.

Syntax: How to Use the Element Logical Record

You must specify an element logical record if an element is defined to DATACOM with a security code.

The element record contains these attributes

`ELEMENTNAME=`*`element`*`, SECURITY=`*`hh`*` ,$`

where:

element

The 5-byte name of the element.

hh

The two-position hexadecimal value of the 1-byte DATACOM security code.

If the Data Dictionary contains a value for the element, this attribute is automatically generated in the Access File when you create a synonym.

Syntax: How to Use the Field Logical Record

The field record contains these attributes

`FIELD=`*`fieldname`*`, SIGN={Y|N}, TYPE={C|P|U|Q} ,$`

where:

SIGN

Has the same value as the option SIGN associated with this field in the Data Dictionary. Valid values are:

Y indicates signed fields. This is the default value.

N indicates unsigned fields.

TYPE

Has the same value as the option TYPE-NUMERIC associated with this field in the Data Dictionary. The synonym is automatically generated with the correct numeric type:

C to indicate a conventional signed field (either positive or negative). Data must have the sign C for a positive signed fields and D for a negative signed fields.

P to indicate a conventional signed positive field. Data must have the sign C.

U to indicate an unconventional signed field (either positive or negative). Data may have the unconventional signs A, B, or E. This is the default value.

Q to indicate an unconventional signed positive field. Data may have the unconventional signs A or E.

Note: This attribute is generated when you create a synonym based on the specified URT or Connection.

Reference: Access File Attributes

The following chart lists Access File attributes generated during synonym creation. Note that attributes vary depending on whether the synonym is generated based on a user requirements table or a connection string.

Keyword	Description
CONNECTION	May be used in the Access file on the segment level. The value of this keyword is the valid connection _name that was previously set by the SET CONNECTION_ATTRIBUTES command. Connection is used in the Access File only when the file level keyword USERTABLE is omitted. Otherwise, connection information is ignored. Values for the keywords USERTABLE, DBID, TRACE, and SEQACCESS (or SKIPSELELCT) are taken from the connection string and used for the current segment only. **Note:** This attribute is generated when you create a synonym based on a specified connection. For related syntax, see *How to Use the Segment Logical Record* on page 477.
DBID	Identifies the numeric, 5-byte DATACOM database ID. It can be 5 digits with a maximum of 5000 values. Values for DBID are taken from the connection string. They will be used for the current segment only. **Note:** This attribute is generated when you create a synonym based on a specified URT. For related syntax, see *How to Use the Segment Logical Record* on page 477.
ELEMENTNAME SECURITY	You must specify an element logical record if an element is defined to DATACOM with a security code. If the Data Dictionary contains a value for the element, this attribute is automatically generated in the Access File when you create a synonym. For related syntax, see *How to Use the Element Logical Record* on page 479.
FIELD	You must specify a field logical record if a file has a numeric (N) or decimal (D) Datacom data type. For related syntax, see *How to Use the Field Logical Record* on page 479.

Keyword	Description
FOUNDLIMIT REJECTLIMIT	You can set interrupt limits to monitor the process of record selection. Accepted (Found) or Rejected records are physical records that either satisfy or do not satisfy the provided search values for non-indexed fields. If required, you can add these attributes to the Access File *manually*. For related syntax, see *How to Use the Header Logical Record* on page 476 and *How to Use the Segment Logical Record* on page 477.
IXFIELD	Is the server field name in the cross-referenced segment that establishes the cross-reference. It is mandatory for all but the root segment. The value(s) of these field(s) must have USAGE and ACTUAL formats comparable to the KEYFLD. You may also specify multiple field names, concatenated with the forward slash symbol (/) without blanks. The keyword value may not span more than one line. The key list can span multiple lines. If required, you can add this attribute to the Access File *manually*. For related syntax, see *How to Use the Segment Logical Record* on page 477.

Keyword	Description
KEYNAME	Is a 5-character alphanumeric name of the key being used in the sequential access commands (GSETL and GETIT). The key name is defined in the Data Dictionary KEY entity-occurrence field, DATACOM-NAME. For fastest sequential retrieval, specify the Native Key, which is in the Data Dictionary Indented Report, where MN stands for mandatory native. If the KEYNAME value is not provided, records are processed in the physical sequence using the commands GSETP/GETPS commands. If a key other than the Native key is specified, the data is internally requested. (Note that Random retrieval is slower than sequential retrieval.) KEYNAME does not have to be the native key. You may assign a different keyname, however, if you do so you may not get all the records. For related syntax, see *How to Use the Segment Logical Record* on page 477.
KEYFIELD	Is the server field name from the parent segment of a cross-reference; it is mandatory for everything but the root segment. You may also specify multiple field names, concatenated with the forward slash symbol (/) without blanks. The keyword value must be contiguous, and on the same line. The key list can span multiple lines. If required, you can add this attribute to the Access File *manually*. For related syntax, see *How to Use the Segment Logical Record* on page 477.
SEGNAME	Identifies the segment name. The Master File SEGMENT attribute is the same as the SEGNAME attribute in the Access File. For related syntax, see *How to Use the Segment Logical Record* on page 477.

Keyword	Description
SEQACCESS	While SEQACCESS is a valid keyword, it is supported for backward compatibility and must be added to the Access File *manually*. You can perform the same function in the connection string using the SKIPSELECT option. Values for SEQACCESS are taken from the connection string. They will be used for the current segment only. For related syntax, see *How to Use the Header Logical Record* on page 476.
TRACE	Enables you to set the accumulation of Compound Boolean Selection (CBS) diagnostics to the DATACOM diagnostics file (PXX) by making "$$ $" the first 3 bytes of the User Information Block for each Datacom command. **Note:** This attribute is generated when you create a synonym based on the specified URT. For related syntax, see *How to Use the Header Logical Record* on page 476.
TABLENAME	Identifies the 3-byte DATACOM table name to which the segment identified by SEGNAME corresponds. You can find this name in the DATA DICTIONARY Element Field Report, under DBNAME. For related syntax, see *How to Use the Segment Logical Record* on page 477.

Keyword	Description
USERTABLE	Identifies the load module that supplies the DATACOM User Requirements Table (URT) information to be dynamically loaded. The URT must contain all the database IDs and file specified in the Master File, or you will not have access to the records. Values for the keyword USERTABLE are taken from the connection string. They will be used for the current segment only. **Note:** This attribute is generated when you create a synonym based in a specified URT. For related syntax, see *How to Use the Header Logical Record* on page 476.

Example: **Access Files Generated by URT and Connection**

This Access File was generated with the URT option on the Create Synonym pane.

```
USERTABLE=ALXURT, TRACE=NO, $
 SEGNAME=ORDERS, TABLENAME=ORD, DBID=10, KEYNAME=ORDID, $
  FIELD=ORD_ID,       SIGN=N, TYPE=C, $
  FIELD=ORD_ID1,      SIGN=N, TYPE=C, $
  FIELD=ORD_ID2,      SIGN=N, TYPE=C, $
  FIELD=DISC_PCT,     SIGN=Y, TYPE=C, $
  FIELD=ORDER_TOTAL, SIGN=Y, TYPE=C, $
  FIELD=FRT_AMT,      SIGN=Y, TYPE=C, $
  FIELD=ORD_AMT,      SIGN=Y, TYPE=C, $
```

This Access file was generated with the Connection option on the Create Synonym pane.

```
SEGNAME=TABLEA, TABLENAME=CAT, CONNECTION=CON02, KEYNAME=NATKY, $
  ELEMENTNAME=ALEX1, SECURITY=e1, $
  FIELD=READING1, SIGN=N, TYPE=C, $
  FIELD=PATMRN,    SIGN=N, TYPE=C, $
  ELEMENTNAME=ALEX2, SECURITY=e2, $
  ELEMENTNAME=ALEX3, SECURITY=e3, $
```

Describing Multi-File Structures for DATACOM

You can describe many different DATACOM data sources in one Master File and Access File pair. However, in the adapter, there must be at least one field in common between any parent and descendant pair of data sources. Each set of related fields must also have comparable USAGE and ACTUAL formats.

Each time you add a descendant segment, you must specify the PARENT attribute in the segment record. This will identify hierarchical relationships between the data sources.

In addition, you must specify the relationship between the fields in the Access File with the KEYFLD and IXFLD attributes:

- The value of the KEYFLD can be a simple field, a DEFINE field, or a list of fields.
- The value of IXFLD can be a simple field, or a list of fields.
- The length, and the format, of KEYFLD and IXFLD must be the same.

There are advantages to defining multiple data sources in a single structure:

- The multi-file structure creates a view of the DATACOM data source.
- You can describe up to 64 separate but related DATACOM logical files as segments in a single Master File. This will allow you to issue a request from any or all of the 64 segments defined in a single Master File without issuing a JOIN command.

To illustrate this concept, we will use the DATACOM data sources PERSON and PAYROLL.

The PAYROLL data source contains information about the wages, commissions, and taxes for each person in the PERSON data source.

Master File PAYROLL

```
FILENAME=PAYROLL, SUFFIX=DATACOM , $
  SEGMENT=PAYROLL, SEGTYPE=S0, $
   FIELDNAME=NUMBER,          ALIAS=PAYRC.0000, USAGE=P5,   ACTUAL=Z5, $
   FIELDNAME=ACTIVITY_CODE,   ALIAS=PAYRC.0001, USAGE=A1,   ACTUAL=A1, $
   FIELDNAME=ACTIVITY_STATUS, ALIAS=PAYRC.0002, USAGE=A1,   ACTUAL=A1, $
   FIELDNAME=CURRENT_RATE,    ALIAS=PAYRC.0003, USAGE=P9.2, ACTUAL=Z8, $
   FIELDNAME=YTD_WAGES,       ALIAS=PAYRC.0004, USAGE=P9.2, ACTUAL=Z8, $
   FIELDNAME=YTD_COMMISSION,  ALIAS=PAYRC.0005, USAGE=P9.2, ACTUAL=Z8, $
   FIELDNAME=YTD_TAX,         ALIAS=PAYRC.0006, USAGE=P9.2, ACTUAL=Z8, $
```

Access File PAYROLL

```
USERTABLE=SAMPURT, TRACE=NO, $
 SEGNAME=PAYROLL, TABLENAME=PAY, DBID=1, KEYNAME=EMPNO, $
  FIELD=NUMBER,          SIGN=N, TYPE=C, $
  FIELD=CURRENT_RATE,    SIGN=N, TYPE=C, $
  FIELD=YTD_WAGES,       SIGN=N, TYPE=C, $
  FIELD=YTD_COMMISSION, SIGN=N, TYPE=C, $
  FIELD=YTD_TAX,         SIGN=N, TYPE=C, $
```

Multi-File Master File

Consider an application that contains both the PERSON and PAYROLL data sources. It is reasonable to generate reports that identify the current salary rate for all employees, or a list of all the employees who have a particular salary rate.

For demonstration purposes, we will define both these DATACOM logical files in one Master File. In all but the top (or root) segment, you must specify the PARENT attribute. PARENT establishes the relationship between two segments

```
PARENT=segname
```

where:

segname

Is the name of the parent of the child segment. If you do not specify a PARENT attribute, it will default to the immediate predecessor of the child segment as the parent.

Example: Multi-File Master File

The following example shows a static Join in a manually combined multi-file Master File with the PARENT attribute added to the descendent segment. The file name PERSPAY identifies the entire Master File.

Master File PERSPAY

```
FILENAME=PERSPAY, SUFFIX=DATACOM , $
 SEGMENT=PERSON, SEGTYPE=S0, $
  FIELDNAME=NUMBER_PERS,     ALIAS=EMDTA.0000, USAGE=P5,   ACTUAL=Z5,  $
  FIELDNAME=NAME,            ALIAS=EMDTA.0001, USAGE=A24,  ACTUAL=A24, $
  FIELDNAME=STREET_ADDRESS,  ALIAS=EMDTA.0002, USAGE=A24,  ACTUAL=A24, $
  FIELDNAME=CITY_ADDRESS,    ALIAS=EMDTA.0003, USAGE=A15,  ACTUAL=A15, $
  FIELDNAME=STATE_ADDRESS,   ALIAS=EMDTA.0004, USAGE=A2,   ACTUAL=A2,  $
  FIELDNAME=ZIP_CODE_LOC,    ALIAS=EMDTA.0005, USAGE=A5,   ACTUAL=A5,  $
  FIELDNAME=SOCIAL_SECURITY, ALIAS=EMDTA.0006, USAGE=P10,  ACTUAL=P5,  $
 SEGMENT=PAYROLL, SEGTYPE=S0, PARENT=PERSON, $
  FIELDNAME=NUMBER_PAY,      ALIAS=PAYRC.0000, USAGE=P5,   ACTUAL=Z5,  $
  FIELDNAME=ACTIVITY_CODE,   ALIAS=PAYRC.0001, USAGE=A1,   ACTUAL=A1,  $
  FIELDNAME=ACTIVITY_STATUS, ALIAS=PAYRC.0002, USAGE=A1,   ACTUAL=A1,  $
  FIELDNAME=CURRENT_RATE,    ALIAS=PAYRC.0003, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_WAGES,       ALIAS=PAYRC.0004, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_COMMISSION,  ALIAS=PAYRC.0005, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_TAX,         ALIAS=PAYRC.0006, USAGE=P9.2, ACTUAL=Z8,  $
```

Multi-File Access File

The Access File for a multi-file structure must have a segment record for each logical segment you define in the Master File.

Each segment record, other than the root, must contain the KEYFLD and IXFLD attributes in addition to the Access File attributes described earlier. These new attributes identify the field(s) in an embedded cross-reference. The common field(s) serve as the cross-referenced link between the two data sources.

The PAYROLL data source is the child, or cross-referenced, segment in the following example. This is important because you identify cross-referencing fields by specifying KEYFLD and IXFLD in the cross-referenced segment record.

KEYFLD

The field name in the parent or host segment, or a list of up to five fields separated by a forward slash symbol (/).

IXFLD

The field name in the child or cross-referenced segment, or a list of up to five fields separated by a forward slash symbol (/).

Example: Multi-File Access File

In the example, the field NUMBER_PERS in the PERSON data source is related to the field NUMBER_PAY in the PAYROLL data source. Both have the same USAGE and ACTUAL data format and length (P5 and Z5); this is a server requirement.

Add the segment record for the PAYROLL data source to the Access File, including the KEYFLD and IXFLD attributes:

Access File PERSPAY

```
USERTABLE=SAMPURT, TRACE=NO, $
 SEGNAME=PERSON, TABLENAME=PMF, DBID=1, KEYNAME=EMPNO, $
  FIELD=NUMBER, SIGN=N, TYPE=C, $
  FIELD=SOCIAL_SECURITY, SIGN=Y, TYPE=C, $
 SEGNAME=PAYROLL, TABLENAME=PAY, DBID=1, KEYNAME=EMPNO,
          KEYFLD=NUMBER_PERS, IXFLD=NUMBER_PAY, $
  FIELD=NUMBER,          SIGN=N, TYPE=C, $
  FIELD=CURRENT_RATE,    SIGN=N, TYPE=C, $
  FIELD=YTD_WAGES,       SIGN=N, TYPE=C, $
  FIELD=YTD_COMMISSION, SIGN=N, TYPE=C, $
  FIELD=YTD_TAX,         SIGN=N, TYPE=C, $
```

Using Multiple Fields to Cross-Reference Data Sources

With the Adapter for DATACOM, you can use up to five fields to establish a relationship or cross-reference between data sources.

For example, matching permutations of values of Z/Y/X/W/V in the KEYFLD and IXFLD attributes can be used to create new cross-referenced fields in the Access File. This is sometimes referred to as using concatenated keys.

Example: Using Multiple Fields to Cross-Reference Data Sources

To illustrate how to use concatenated keys, we will alter the PERSPAY multi-file Master and Access Files as shown in the following example:

1. Replace the field NUMBER_PERS in the PERSON segment with the LAST_NAME and FIRST_NAME fields.
2. In the PAYROLL segment, replace the field NUMBER_PAY with LN and FN.
3. Separate each field that is part of the cross-reference with a forward slash symbol (/).

```
FILENAME=PERPAY, SUFFIX=DATACOM , $
 SEGMENT=PERSON, SEGTYPE=S0, $
  FIELDNAME=LAST_NAME,       ALIAS=EMDTA.0000, USAGE=A15,  ACTUAL=A15, $
  FIELDNAME=FIRST_NAME,      ALIAS=EMDTA.0001, USAGE=A10,  ACTUAL=A10, $
  FIELDNAME=NAME,            ALIAS=EMDTA.0002, USAGE=A24,  ACTUAL=A24, $
  FIELDNAME=STREET_ADDRESS,  ALIAS=EMDTA.0003, USAGE=A24,  ACTUAL=A24, $
  FIELDNAME=CITY_ADDRESS,    ALIAS=EMDTA.0004, USAGE=A15,  ACTUAL=A15, $
  FIELDNAME=STATE_ADDRESS,   ALIAS=EMDTA.0005, USAGE=A2,   ACTUAL=A2,  $
  FIELDNAME=ZIP_CODE_LOC,    ALIAS=EMDTA.0006, USAGE=A5,   ACTUAL=A5,  $
  FIELDNAME=SOCIAL_SECURITY, ALIAS=EMDTA.0007, USAGE=P10,  ACTUAL=P5,  $
 SEGMENT=PAYROLL, SEGTYPE=S0, PARENT=PERSON, $
  FIELDNAME=LN,              ALIAS=EMDTA.0000, USAGE=A15,  ACTUAL=A15, $
  FIELDNAME=FN,              ALIAS=EMDTA.0001, USAGE=A10,  ACTUAL=A10, $
  FIELDNAME=ACTIVITY_CODE,   ALIAS=PAYRC.0002, USAGE=A1,   ACTUAL=A1,  $
  FIELDNAME=ACTIVITY_STATUS, ALIAS=PAYRC.0003, USAGE=A1,   ACTUAL=A1,  $
  FIELDNAME=CURRENT_RATE,    ALIAS=PAYRC.0004, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_WAGES,       ALIAS=PAYRC.0005, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_COMMISSION,  ALIAS=PAYRC.0006, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_TAX,         ALIAS=PAYRC.0007, USAGE=P9.2, ACTUAL=Z8,  $
```

These multiple fields will now become the KEYFLD and IXFLD attributes in the Access File.

Separate each field from the next with the forward slash symbol (/), and add these attributes to the PAYROLL segment record in the Access File:

Access File PERPAY

```
USERTABLE=SAMPURT, TRACE=NO, $
 SEGNAME=PERSON, TABLENAME=PMF, DBID=1, KEYNAME=EMPNO, $
  FIELD=SOCIAL_SECURITY, SIGN=Y, TYPE=C, $
 SEGNAME=PAYROLL, TABLENAME=PAY, DBID=1, KEYNAME=EMPNO,
         KEYFLD=LAST_NAME/FIRST_NAME, IXFLD=LN/FN, $
  FIELD=CURRENT_RATE,    SIGN=N, TYPE=C, $
  FIELD=YTD_WAGES,       SIGN=N, TYPE=C, $
  FIELD=YTD_COMMISSION, SIGN=N, TYPE=C, $
  FIELD=YTD_TAX,         SIGN=N, TYPE=C, $
```

Reviewing a DATACOM Detail Report

Although the synonym creation facility generates metadata for a DATACOM data source, you may find it useful to review internal information, as it is maintained by DATACOM, in a detail report like the sample shown in this section.

Example: **Detailed DATACOM Field Report**

This is a sample DATACOM field report. (Note that non-essential information has been removed from this multi-page report, as indicted by ellipses, to focus your attention on the basic content.)

Data Retrieval Logic for DATACOM

This section describes the three types of DATACOM record retrieval commands generated by the Adapter for DATACOM:

- **Sequential Logical Retrieval Commands:** *GSETL and GETIT*. These commands are issued by the adapter only for the root of the accessed subtree, and only if the request does not specify any record selection criteria on that segment in the Access File and the value of the parameter KEYNAME is provided.
- **Sequential Physical Retrieval Commands:** *GSETP and GETPS*. These commands are issued by the adapter only for the root of the accessed subtree, and only if the request does not specify any record selection criteria on that segment in the Access File and the value of the parameter KEYNAME is not provided.
- **Compound Boolean Selection Commands:** *SELFR and SELNR*. These commands are issued for DATACOM records when there are available selection criteria.

Note: Sequential retrieval commands are used under each of the following circumstances:

- The parameter SEQACCESS=YES is specified in the Access File for the root segment.
- The SET SKIPSELECT =YES command is issued.
- The Skipselect option is specified in the connection string.

GSETL and GETIT

When the adapter determines sequential retrieval needs to be done for the root segment, it issues a GSETL command. It uses the KEYNAME, specified in the Access File, and establishes the starting position at the beginning (lowest value) of the key. Only one GSETL command is issued per request.

GETIT commands follow the GSETL command. They retrieve the element(s) for each root record indexed by the key. The adapter requests only the elements necessary to satisfy the request. If there are no sort fields in the request, the answer set is produced, in ascending order, by the key. GETIT commands are issued repeatedly until DATACOM issues a return code of 19 (End of Table).

As long as the KEYNAME in the Access File is the Native Key, the adapter retrieves all records that correspond to a DATACOM table.

GSETP and GETPS

Only one GSETP command is issued per request. GETPS commands follow the GSETP command. They retrieve the element(s) for each root record by physical layout in the database. GETPS commands are issued repeatedly until DATACOM issues a return code of 19 (End of Table).

SELFR and SELNR

The adapter uses two types of selection criteria to construct the SELFR call to DATACOM for a record:

1. All the values supplied in WHERE statements that mention a field in the segment and have any of these types of operators:

```
EQ          GT          NE

IS          LE          CONTAINS

GE          LT          FROM...TO
```

   Note: The SELFR request does not use selection on defined fields.

2. DBA value selection criteria on the segment.

The adapter generates a SELFR command, using all available selection criteria on the segment. This builds a list of records which match the selection criteria and returns the first record. The list is built in the temporary index area of the DATACOM data source.

For a descendant record with SEGTYPE=U, the SELFR retrieves the unique descendant. No SELNR command is issued. Otherwise, the SELFR command is followed by SELNR command(s) which retrieve the records listed in the temporary index. A SELNR is issued repeatedly until DATACOM issues a return code of 14 (End/Beginning of Set).

Note: An additional selection command, SELST, enables you to interrupt record selection if records are rejected from the index based on the REJECTLIMIT attribute in the Access File. For related information, see FOUNDLIMIT and REJECTLIMIT in *Access File Attributes* on page 480.

Example: Using a Sequence of Calls for a Multi-Segment Request

To illustrate the sequence of calls the adapter must make to DATACOM to service a multi-segment request, we will use the PERSPAY data source.

Master File PERSPAY

```
FILENAME=PERSPAY, SUFFIX=DATACOM , $
 SEGMENT=PERSON, SEGTYPE=S0, $
  FIELDNAME=NUMBER_PERS,      ALIAS=EMDTA.0000, USAGE=P5,    ACTUAL=Z5, $
  FIELDNAME=NAME,             ALIAS=EMDTA.0001, USAGE=A24,   ACTUAL=A24, $
  FIELDNAME=STREET_ADDRESS,   ALIAS=EMDTA.0002, USAGE=A24,   ACTUAL=A24, $
  FIELDNAME=CITY_ADDRESS,     ALIAS=EMDTA.0003, USAGE=A15,   ACTUAL=A15, $
  FIELDNAME=STATE_ADDRESS,    ALIAS=EMDTA.0004, USAGE=A2,    ACTUAL=A2,  $
  FIELDNAME=ZIP_CODE_LOC,     ALIAS=EMDTA.0005, USAGE=A5,    ACTUAL=A5,  $
  FIELDNAME=SOCIAL_SECURITY, ALIAS=EMDTA.0006, USAGE=P10,   ACTUAL=P5,  $
 SEGMENT=PAYROLL, SEGTYPE=S0, PARENT=PERSON, $
  FIELDNAME=NUMBER_PAY,       ALIAS=PAYRC.0000, USAGE=P5,    ACTUAL=Z5, $
  FIELDNAME=ACTIVITY_CODE,    ALIAS=PAYRC.0001, USAGE=A1,    ACTUAL=A1,  $
  FIELDNAME=ACTIVITY_STATUS, ALIAS=PAYRC.0002, USAGE=A1,    ACTUAL=A1,  $
  FIELDNAME=CURRENT_RATE,     ALIAS=PAYRC.0003, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_WAGES,        ALIAS=PAYRC.0004, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_COMMISSION,  ALIAS=PAYRC.0005, USAGE=P9.2, ACTUAL=Z8,  $
  FIELDNAME=YTD_TAX,          ALIAS=PAYRC.0006, USAGE=P9.2, ACTUAL=Z8,  $
```

In the following request

```
SELECT NAME, NUMBER_PERS, SOCIAL_SECURITY, YTD_WAGES, YTD_COMMISSION,
   YTD_TAX
FROM PERSPAY
WHERE ACTIVITY_STATUS = 'A';
```

PERSON is a referenced segment; it is the root of the accessed subtree. NAME, NUMBER_PERS, and SOCIAL_SECURITY are the names of fields on this segment.

However, there are no available selection criteria for the PERSON segment (ACTIVITY_STATUS is a field on the PAY segment). Therefore, the adapter will first issue a GSETL command for the PAYROLL MASTER File (PMF), using the NUMBER_PERS Native Key. The GSETL command is followed by a GETIT command to retrieve the first root record, the EMDTA element.

Since the server always processes from top-to-bottom, left-to-right, all the related descendants of this first root record must be retrieved before proceeding to the next root record.

Next, to generate the SELFR call to retrieve PAY data source records related to the PERSON parent, two pieces of selection criteria will be used: the value of NUMBER_PERS (the KEYFLD) from the PMF record, and the selection criteria on ACTIVITY_STATUS.

The first SELFR call to DATACOM for the first root record will retrieve a PAY record with NUMBER_PAY equal to NUMBER_PERS, and ACTIVITY_STATUS equal to 'A'. Subsequent SELNR calls (SEGTYPE=SO) may retrieve other records with those same values.

After DATACOM returns a 14 for the PAY data source, a second GETIT command will be generated for a PMF record. The value of this record's NUMBER_PERS field is used, with ACTIVITY_STATUS EQ A, to generate a new set of SELFR/SELNR calls to retrieve related PAY records.

This process will be repeated until DATACOM returns a 19 for the GETIT command on the root, signifying that all records have been retrieved and processed. If the request were

```
SELECT NAME NUMBER_PERS SOCIAL_SECURITY YTD_WAGES YTD_COMMISSION YTD_TAX
FROM PERSPAY
WHERE ACTIVITY_STATUS = 'A' AND
STATE_ADDRESS IN ('CT', 'RI', 'MA', 'VT', 'NH', 'ME';
```

SELFR/SELNR commands would be issued instead of GSETL/GETIT commands, with the five STATE_ADDRESS values (STATE_ADDRESS is a field on the PERSON segment). The process however, would be the same.

Finally, keep in mind:

- The adapter will retrieve all descendant records of one parent occurrence before it will retrieve the next parent record.
- The higher you put your selection criteria in the hierarchical structure, the more efficient processing will be.

Chapter 19

Using the Adapter for Db2

The Adapter for Db2 allows applications to access Db2 data sources. The adapter converts data or application requests into native Db2 statements and returns optimized answer sets to the requesting program.

The adapter supports the execution of Db2 stored procedures and Db2 Cube Views.

In this chapter:

Preparing the Db2 Environment

The CLI version of the Adapter for Db2 requires the installation of the Db2 Client. The CAF version requires Db2 load libraries. The JDBC version requires jar files to be installed. All versions of the adapter allow connection to local or remote Db2 servers.

Procedure: How to Set Up the Environment on Microsoft Windows

Two versions of the Adapter for Db2 are available in this environment. Each one requires different pre-configuration steps prior to using the Web Console.

Db2 CLI:

The adapter supports Unicode data. You must add DB2CODEPAGE=1208 to the Windows environment either by:

- Setting the environment variable in Windows.

- Setting the environment variable in the edaenv.cfg file.

```
DB2CODEPAGE=1208
```

Db2 JDBC:

Identify the location of the JDBC Driver files by adding them to the environment variable CLASSPATH before server startup. For example, set:

```
CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
```

Procedure: How to Set Up the Environment on UNIX

Two versions of the Adapter for Db2 are available in this environment. Each one requires different pre-configuration steps prior to using the Web Console.

Db2 CLI:

- Specify the Db2 instance to access using the UNIX environment variable $DB2INSTANCE. For example:

  ```
  export DB2INSTANCE=db2
  ```

- Specify the location of the Db2 instance you wish to access using the UNIX environment variable $INSTHOME. For example:

  ```
  export INSTHOME=/usr/db2
  ```

- Specify the path to the Db2 shared library using the UNIX environment variable $LD_LIBRARY_PATH. For example:

  ```
  export LD_LIBRARY_PATH=$INSTHOME/sqllib/lib:$LD_LIBRARY_PATH
  ```

  Note that if the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.

- **Unicode support.** The adapter supports Unicode data. You must set the LANG environment variable in the edastart file or in a separate shell file. For example, for American English, you would export the following variable:

  ```
  export LANG=EN_US.UTF-8
  ```

  To take advantage of adapter support for Unicode data, the Reporting Server must be configured with code page 65001.

Db2 JDBC:

Identify the location of the JDBC Driver files by adding them to the environment variable CLASSPATH before server startup. For example, issue the following commands:

```
CLASSPATH=/usr/driver_files/mydriver.jar;
$CLASSPATH
export CLASSPATH
...
```

Procedure: How to Set Up the Environment on z/OS

Two deployment options are supported on this platform that support the CLI and CAF versions of the adapter. Each one requires different pre-configuration steps prior to using the Web Console.

- **Db2/CAF:** Utilizes embedded SQL using the IBM/Db2 for z/OS Call Attach Facility to access the Db2 RDBMS.
  - **For HFS deployment.** The Web Console configuration panel for the bind operation has three options (Yes, Create JCL only, and No). Select *Yes* to execute a shell script ($EDAHOME/bin/genidb2.sh) to bind your plan to Db2. If you do not have bind authority over the Db2 subsystem, then select *Create JCL* only so that your Db2 DBA can run member GENDB2 in the configuration data set for you. Select *No* if you do not want to run the bind script or create the JCL. The Adapter for Db2 can now be used.
  - **For PDS deployment.** The Web Console configuration panel for the bind operation will only create the JCL member GENDB2 in the configuration data set. This job will have to be submitted by your Db2 DBA to bind the plan to Db2 before the Db2 adapter can be used.

  For the naming convention for the configuration data set, see the installation manual for z/OS.
- **Db2/CLI:** Utilizes IBM/Db2 for z/OS Call Level Interface calls to access the Db2 RDBMS.

  The adapter makes use of the Db2 plan DSNACLI. To ensure that all users of the adapter have access to this plan, issue the following command in the Db2 environment:

  ```
  GRANT EXECUTE ON PLAN DSNACLI TO PUBLIC
  ```

  The adapter also uses the DSNAOINI environment variable or DSNAOINI DDNAME pointing to the Db2 CLI initialization file. You can provide this variable at installation time using the ISETUP panels, or you can add the variable manually to the EDAENV member of the installation data set after completing the installation.

The following is an example for the DSNAOINI environment variable.

```
DSNAOINI=full_path_name/db2cli.ini
```

The following is an example for the DSNAOINI DDNAME.

```
//DSNAOINI DD DSN=library(member),DISP=SHR
```

or

```
//DSNAOINI DD DSN=dataset,DISP=SHR
```

Unicode support. The adapter supports Unicode data in Db2 databases that have been created with the CCSID UNICODE option. You must ensure that the DSNAOINI environment variable or DDNAME points to a configuration file containing the following specification:

```
CURRENTAPPENSCH=UNICODE
```

Procedure: How to Access a Remote Database Server on IBM i

Using the standard rules for deploying the Db2 CLI Client, the server supports connections to:

- Local Db2 servers.
- Remote Db2 servers.

When using Db2/CLI to connect to a remote Db2 data source, the Db2 client catalog must contain an entry for the node where the remote data source resides and an entry for the remote database name.

Support for Remote Aliases. An alias entry in a local Db2 system that points to a table in another Db2 system is only supported with the CREATE SYNONYM command. It is not supported for metadata queries when SET ENGINE=DB2 is in effect.

Configuring the Adapter for Db2

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

In order to connect to the Db2 database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user*.prf), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user*.prf), or in a group profile (if supported on your platform).

You can declare connections to more than one Db2 database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Db2 Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   The Adapters folder opens.
2. Expand the *Available* folder, if it is not already expanded or click +.
3. Expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the connection attributes reference.

6. Click *Configure* or *Add*. The configured adapter is added to the Adapters list in the navigation pane.

Reference: Connection Attributes for Db2 With CLI

The Db2 adapter in under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource/DSN

Db2 data source name (DSN), is a locally registered alias of a remote DB2 database. There is no default data source name. You must enter a value.

For IBM i, this is the Remote Database Directory entry or *LOCAL (for local host).

For z/OS, this is the Db2 location name as specified in the Db2 communications data source.

DSN-less

Applies to Linux, UNIX, and Windows. Check this box to specify the following connection parameters instead of a DSN. Note that bulk load is not supported with this type of connection.

Host Name

Is the name of the host where the Db2 server is running.

Port Number

Is the port number on which the Db2 server is listening.

Database Name

Is the Db2 database name.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Trusted Context

Select this check box to enable a Db2 trusted context, which is a database object that defines a trust relationship for a connection between the database and an external application server. The trust relationship is based upon the attributes defined in the trusted context object.

If you select Enable, the following is added after the password in the SET CONNECTION ATTRIBUTES command:

```
:'trusted_context=y'
```

For example, assume the Reporting server is configured with LDAP security and the WebFOCUS Client is configured with SECURITY TRUSTED. From the WebFOCUS Client, the Web Console is opened without an authentication prompt and connection to the server is trusted. The adapter connects to the Db2 database with the user ID in the connection string. It checks for a trusted context object and then switches users.

Additional connection string keywords (Optional)

You can enter any additional connection string keywords separated by semicolons (;). Each keyword consists of an attribute and value pair in the form attribute=value.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Reference: Connection Attributes for Db2 With CAF

This list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

SSID

Db2 SSID that is to be accessed.

Plan

Plan name to be bound to Db2.

Execute Db2 BIND Command

For HFS deployment, indicates whether to bind the plan. Yes is the default value.

DSNCLST Library Name

Name of the Db2 installation DSNCLST library.

This attribute is available only if you choose to bind your program.

ENCODING

Specifies the application encoding for all host variables in the plan. Valid values are ASCII, EBCDIC, UNICODE, ccsid.

DSNLOAD Library Name

Name of the Db2 installation DSNLOAD Library.

If this value was supplied at installation time, it will be displayed here.

Owner

Authorization ID of the Owner of the Plan.

This attribute is available only if you choose to bind your program

Isolation Level

Isolation level. CS is the default value.

This attribute is available only if you choose to bind your program.

Grant

Grants plan execution to public.

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down list and enter a name in the Profile Name input box (the extension is added automatically).

Reference: Connection Attributes for Db2 With JDBC

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the JDBC data source.

Driver name

Name of the JDBC driver.

See the driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names that will be available for Java Services. The value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Reference: Connection Attributes for Db2 With SQL

For a full IBM i installation, once the adapter is configured for IBM i you must go to the Change Settings pane and set an isolation level. Failure to set an explicit isolation level causes Db2 to generate multiple commit/rollback warning messages in the adapter's job log. Any isolation level may be selected for the purpose of stopping the multiple warning messages. For more information, see *Controlling Types of Locks on IBM i* on page 534.

Note: In the IBM i environment, isolation level is preset to NC (No Commit) so no action is required.

Syntax: How to Declare Connection Attributes Manually

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to Db2, at connection time, for authentication.

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES connection DSN_name/userid,password
```

Password passthru authentication. The user ID and password are explicitly specified for each connection and passed to Db2, at connection time, for authentication.

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES connection DSN_name/
```

Trusted authentication. The adapter connects to Db2 as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

The available parameters are:

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES connection DSN_name/,
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and DSN_*name*.

DSN_*name*

Is the Db2 data source name (DSN) you wish to access. It must match an entry in the odbc.ini file.

userid

Is the primary authorization ID by which you are known to Db2.

password

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command allows the application to access the Db2 database server named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES CON01 SAMPLESERVER/MYUSER,PASS
```

The following SET CONNECTION_ATTRIBUTES command connects to the Db2 database server named SAMPLESERVER using Password Passthru authentication:

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES CON01 SAMPLESERVER/
```

The following SET CONNECTION_ATTRIBUTES command connects to a local Db2 database server using operating system authentication:

```
ENGINE DB2 SET CONNECTION_ATTRIBUTES CON01 SAMPLESERVER/,
```

Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Migrate option on the Web Console migrates your server settings to the newer release. To access this option, choose *Workspace*, then *Migrate* from the menu bar. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the *Migrate* button. This is the recommended approach.

If you choose *not* to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=*value*.

  For example, suppose that prior 7.6.1 the connection was defined as:

  ```
  ENGINE DB2 SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
  ```

  When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

  ```
  CONNECTION=DSN_A
  ```

  If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

  ```
  ENGINE DB2 SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
  ```

DB2 CURRENT SQLID (z/OS)

Db2 accepts two types of IDs, the primary authorization ID and one or more optional secondary authorization IDs. It also recognizes the CURRENT SQLID setting.

Any interactive user or batch program that accesses a Db2 subsystem is identified by a primary authorization ID. A security system, such as RACF, normally manages the ID. During the process of connecting to Db2, the primary authorization ID may be associated with one or more secondary authorization IDs (usually RACF groups). Each site controls whether it uses secondary authorization IDs. For more information about using the adapter in conjunction with external security packages, see the server manual for your platform.

The primary authorization ID is the same ID passed to the server at connect time. This user ID is then used to connect to the Db2 subsystem.

The Db2 Data Source Administrator may grant privileges to a secondary authorization ID that are not granted to the primary ID. Thus, secondary authorization IDs provide the means for granting the same privileges to a group of users. (The DBA associates individual primary IDs with a secondary ID and grants the privileges to the secondary ID.)

The DB2 CURRENT SQLID may be the primary authorization ID or any associated secondary authorization ID. At the beginning of the session, the CURRENT SQLID is the primary authorization ID.

Syntax: How to Reset CURRENT SQLID

You can reset the CURRENT SQLID in a stored procedure or a profile using the following adapter command using the following parameters:

```
ENGINE DB2 SET CURRENT SQLID = 'sqlid'
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`sqlid`

Is the primary or secondary authorization ID, which must be enclosed in single quotation marks as shown. All Db2 security rules are respected.

The CURRENT SQLID is the default owner ID for Db2 objects, such as tables or indexes, created with dynamic SQL commands. The CURRENT SQLID is also the sole authorization ID for GRANT and REVOKE commands. It must have all the privileges needed to create objects as well as GRANT and REVOKE privileges. In addition, the CURRENT SQLID is the implicit owner for unqualified table names.

Other types of requests, such as SQL SELECT, INSERT, UPDATE, or DELETE requests, automatically search for the necessary authorization using the combined privileges of the primary authorization ID and all of its associated secondary authorization IDs, regardless of the DB2 CURRENT SQLID setting.

The CURRENT SQLID setting remains in effect until the thread to Db2 is disconnected, when it reverts to the primary authorization ID.

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE DB2 SET DEFAULT_CONNECTION connection
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE DB2 SET DEFAULT_CONNECTION SAMPLE
```

Controlling Connection Scope

The SET AUTODISCONNECT and AUTOCLOSE commands control the persistence of connections when using the adapter.

Controlling Connection Scope With AUTOCLOSE (z/OS)

SET AUTOCLOSE initiates the Db2 Call Attachment Facility (CAF) CLOSE operation. It determines how long a thread (the connection between the application program in the user's address space and the Db2 application plan) is open. The thread is not the same as the address space connection to Db2; that connection is controlled by the AUTODISCONNECT setting.

In the server, an application program is one of the following:

- The dynamic Adapter for Db2.

- A CALLPGM subroutine using embedded SQL (non-CLI).

Generally speaking, each program has a corresponding plan or package.

A site that installs a Db2 subsystem determines the maximum number of concurrent users (threads) the subsystem will support. Since each user requires enough virtual storage for their application plan, this setting controls the amount of storage the site wants to allocate to active Db2 users at any one time.

The CAF CLOSE command deallocates the Db2 thread, releasing the virtual storage for the application plan. Db2 requires that an existing thread to a plan be closed before a thread to another plan is opened. If a thread is closed without a subsequent OPEN operation, the closed thread becomes "inactive"; the user is still connected to Db2, but not to a particular application plan. The user (task) still owns the thread; it is not available to other users. To release the thread, the user must disconnect completely from Db2.

Note: The term pseudo-conversational describes the type of transaction processing provided when you use AUTOCLOSE ON COMMIT.

Syntax: How to Control Connection Scope With AUTOCLOSE

```
ENGINE DB2 SET AUTOCLOSE ON {FIN|COMMIT}
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`AUTOCLOSE`

Issues the Db2 Call Attach Facility (CAF) CLOSE operation.

`FIN`

Disconnects automatically only after the server session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Controlling Connection Scope With AUTODISCONNECT

AUTODISCONNECT completely detaches the users address space (or task) from Db2. After a DISCONNECT, the task must re-establish its connection to Db2 before performing any data source work. The tasks that frequently issue the DISCONNECT command are connected to Db2 for shorter periods of time, allowing other tasks to connect and acquire threads as needed. However, there is significant system overhead associated with frequently connecting and disconnecting, and the possibility exists that no thread will be immediately available when the task attempts to reconnect.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

Syntax: How to Control Connection Scope With AUTODISCONNECT

```
ENGINE DB2 SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Db2 Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Db2 data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Db2 table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note that creating a synonym for a stored procedure is described with reporting against a stored procedure, in *Generating a Synonym for a Stored Procedure* on page 525.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console Applications page, click *Get Data*.
2. Right-click a connection for a configured adapter.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click the *Add* button.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym is created and added under the specified application directory.

Note:

- When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Db2

The following list describes the synonym creation parameters for which you can supply values.

Object Type

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

- If you select *Aliases* as a filtering option and the Alias points to a Remote Db2 system, it must be Version 8 or higher. Only one level of Remote Db2 is supported.
- If you select *Nicknames* as a filtering option on platforms where Db2 supports the Nickname object type (Windows and UNIX), a basic synonym is created for this type of Db2 object; no Titles, Remarks, or Keys are recorded in the synonym. The user ID who creates the synonym must have SELECT authority for this object type.

Important: If you select Stored Procedures as your object type, the input parameters will be a little different from those described here. For details, see *Reporting Against a Db2 Stored Procedure* on page 525.

Owner/Schema

Selecting this option adds the Owner/Schema and Object Name parameters to the screen. Select an owner/schema from the drop-down list or type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. Then click *Search*. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

Object Name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen. Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. Then click *Search*. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Filter by Library/Object Name (IBM i)

To avoid the return of an extremely large and potentially unmanageable list, always supply a value for Library or Object Name:

- **Library.** Type a string for filtering the Library (or Db2 Collection), inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner IDs begin with the letters ABC; %ABC to select tables or views whose owner IDs end with the letters ABC; %ABC% to select tables or views whose owner IDs contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the table, view, or object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all tables, views, or objects whose names begin with the letters ABC; %ABC to select all tables, views, or objects whose names end with the letters ABC; %ABC% to select all tables, views, or objects whose names contain the letters ABC at the beginning, middle, or end.

Note: When you create a synonym for Db2 on the IBM i platform, standard IBM i naming conventions apply to the target data source. Therefore, the Adapter for Db2 supports the use of double-quotation marks around any library name and/or file name that contains lowercase or NLS characters.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Row Limit

Select the number of objects to display on the Create Synonym page.

For Subquery

Only available when *External SQL Scripts* is selected from the object type drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support Report* on page 1211.

Create: Cluster Synonym or Base Synonyms

Select the button for the type of synonym you want to create.

One-part name (IBM i)

On the IBM i platform, the One-part name check box is unchecked by default. The unchecked behavior generates a table name that includes the explicit name of the library containing the table. For example, if you specified a library on the first Create Synonym pane, a qualified name like the following is automatically created in the Access File for a TABLE or VIEW:

```
TABLENAME=MYLIB/MYTABLE
```

For a Stored Procedure, this would be a Db2 RPC and identified in the Access File as:

```
STPNAME=MYLIB/MYPROC
```

With this explicit type of entry in the Access File, at run-time the library is directly referenced and the object opened.

If you select the check box, the explicit library name is not stored in the metadata (Access File). When the synonym is generated, the library portion of the table name is omitted from the Access File, and appears as follows:

```
TABLENAME=MYTABLE
```

or

```
STPNAME=MYPROC
```

With this type of entry in the Access File (one-part name), the Db2 library search path will be used at run time. The exact composition varies depending on if Db2 is configured as a CLI or SQL connection.

For CLI configured servers, the search path will be the default library of Db2 for a CLI connected user (usually QSYS and QSYS2 plus the default library of the user). It is also controllable by use of a passthru command setting the path, such as SLQ DB2 SET PATH “QSYS”,”QSYS2”,”FOO”,”EXTRAFOO” as issued within a requests FOCEXCEC procedure or a profile. For SQL configured servers, the search path will be *LIBL. The library path of the process can be controlled by commands, such as ADDLIBLE, either before server start or as issued within a requests FOCEXCEC procedure or a profile.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Fact or Dimension

You can check Fact or Dimension to generate the segment as a fact table or a dimension segment. If you are creating a cluster synonym, you can right-click a selected fact table and select *Show Related Dimensions* or *Add Related Dimensions* to show a list of related dimensions or add related dimensions to the synonym.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- When creating base synonyms, you can select all tables in the list by clicking the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Once you have selected the objects for which you want to create synonyms, click the *Create Base Synonyms* or *Create Cluster Synonym* button on the ribbon.

Example: Sample Generated Synonym

An Adapter for Db2 synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=DB2 ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4,    I9,  I4  ,MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25 ,MISSING=ON  ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9,  I4  ,MISSING=ON  ,$
```

Generated Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DB1,KEYS=1,WRITE=YES,$
```

Reference: Mapping Db2 Table and Column Attributes Into a Synonym

These mappings are OS-system specific:

Mapping Db2 Table Attributes

Platform	Db2 Table Attribute	Mapping in Synonym	Notes
UNIX/Windows	COMMENT	REMARKS	
IBM i	REMARK LABEL	REMARKS	The synonym creation facility picks up a Db2 table TABLE level REMARK or LABEL value, whichever is not null, for use as a Master File REMARKS= value. If the Db2 table has both a populated REMARK and a populated LABEL, the REMARK value will be used.
z/OS	COMMENT LABEL	REMARKS	The synonym creation facility picks up a Db2 table TABLE level COMMENT or LABEL value, whichever is not blank, for use as a Master File REMARKS= value. If the Db2 table has both a populated COMMENT and a populated LABEL, the COMMENT value will be used.

Mapping Db2 Column Attributes

Platform	Db2 Column Attribute	Mapping in Synonym	Notes
UNIX/Windows	COMMENT	DESCRIPTION	
IBM i	LABEL COMMENT	TITLE DESCRIPTION	

Platform	Db2 Column Attribute	Mapping in Synonym	Notes
z/OS	LABEL COMMENT	TITLE DESCRIPTION	

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Name of the table or view. This value can include a location or owner name as follows: TABLENAME=[*location.*][*owner.*]*tablename* **Note:** Location is valid only with Db2 CAF and specifies the subsystem location name. For IBM i, the syntax is: TABLENAME=[*library/*]*tablename*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local database server. Absence of the CONNECTION attribute indicates access to the default database server.
DBSPACE	Optional keyword that indicates the storage area for the table. For example: *datasource.tablespace* DATABASE *datasource*

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. This attribute requires the columns that constitute the key to be described first in the Master File. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.
AUTO INCREMENT	Set to Yes to enable autoincrementing.

Keyword	Description
START	Initial value in incrementing sequence
INCREMENT	Increment interval.
INDEX_NAME INDEX_UNIQUE INDEX_COLUMNS INDEX_ORDER	Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Db2 Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Controlling the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Db2 data types VARCHAR. By default, the server maps this data type as variable character (A*n*V).

The following table lists data type mappings based on the value of VARCHAR.

		VARCHAR ON		VARCHAR OFF	
Db2 Data Type	**Remarks**				
VARCHAR (*n*)	*n* is an integer between 1 and 32768	A*n*V	A*n*V	A*n*	A*n*

Syntax: **How to Control the Mapping of Variable-Length Data Types**

```
ENGINE DB2 SET VARCHAR {ON|OFF}
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Maps the Db2 data type VARCHAR as variable-length alphanumeric (A*n*V). This is required for Unicode environments. ON is the default value.

`OFF`

Maps the Db2 data type VARCHAR as alphanumeric (A).

BLOB Activation

Db2 data types that support the *for bit data* attribute including VARCHAR(n), where *n* > 256 and LONG VARCHAR, can be supported in the server as Binary Large Objects (BLOBs). This support is for both read and write access.

Syntax: How to Activate BLOB

To activate this support, you must issue the following command in one of the supported server profiles

```
ENGINE DB2 SET CONVERSION LONGCHAR BLOB
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`BLOB`

Activates long binary support. ALPHA is the default value.

BLOB Read/Write Support

For Db2 data types VARCHAR (>256) and LONG VARCHAR which have the *for bit data* attribute, the server provides read and write support using three server remote procedures routines. These routines are:

Routine	Used to...
EDABS	Send binary image data to the server.
EDABE	Mark the end of the binary image.
EDABK	Purge the binary image from server storage.

The sequence of operations for the client application is:

1. Converts every binary byte of the image into 2 bytes of hexadecimal data and stores the result in an internal buffer. If the image is large, this could be split into manageable pieces.
2. Sends the converted binary bytes to the server using remote procedure EDABS. The server converts the hex data back to binary and stores the image ready for INSERT/UPDATE into Db2.
3. Repeats steps 1 and 2 until the complete image is sent to the server in hex format. It then sends remote procedure EDABE to mark the end of the image.
4. The client application prepares an SQL INSERT/UPDATE using parameter markers for the columns of the row.
5. The client application issues a BIND for the columns using CHAR(16) for the image column.
6. The client application issues an EXECUTE USING command giving the data values for the row columns but using 'BLOB' for the image. The row will be INSERTed/UPDATEd using the image buffer stored on the server.
7. Once the application has finished with the stored image on the server (and COMMITed the data), it should send the EDABK Remote Procedure to release server storage.

For full details and examples of how to maintain Db2 *for bit data* columns, see the *API Reference* and *Connector for ODBC* manuals.

Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```
ENGINE DB2 SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96

Reporting Against a Db2 Stored Procedure

You can use a reporting tool, such as a SELECT statement or TABLE command, to execute Db2 stored procedures and report against the output parameters and answer set of a procedure. Among the benefits of this method of executing a stored procedure are:

- The retrieval of output parameters, OUT parameters, and INOUT parameters in OUT mode, as well as the answer set. (Other methods of invocation retrieve the answer set only.)
- The ease with which you can process, format, and display output parameters and the answer set, using TABLE and other reporting tools.

To report against a stored procedure:

1. **Generate a synonym** for the stored procedure answer set, as described in *Generating a Synonym for a Stored Procedure* on page 525.
2. **Create a report procedure,** as described in *Creating a Report Against a Stored Procedure* on page 529.
3. **Run the report.** This executes the stored procedure and reports against any output parameters (OUT and INOUT in OUT mode), and any answer set fields, specified in the report.

Generating a Synonym for a Stored Procedure

A synonym describes the stored procedure parameters and answer set.

An answer set structure may vary depending on the input parameter values that are provided when the procedure is executed. Therefore, you need to generate a separate synonym for each set of input parameter values that will be provided when the procedure is executed at run time. For example, if users may execute the stored procedure using three different sets of input parameter values, you need to generate three synonyms, one for each set of values. (Unless noted otherwise, "input parameters" refers to IN parameters and to INOUT parameters in IN mode.)

There is an exception: if you know the internal logic of the procedure, and are certain which range of input parameter values will generate each answer set structure returned by the procedure, you can create one synonym for each answer set structure, and for each synonym simply provide a representative set of the input parameter values necessary to return that answer set structure.

A synonym includes the following segments:

- INPUT, which describes any IN parameters and INOUT parameters in IN mode.

  If there are no IN parameters or INOUT parameters in IN mode, the segment describes a single dummy field.

- OUTPUT, which describes any OUT parameters and INOUT parameters in OUT mode.

  If there are no OUT parameters or INOUT parameters in OUT mode, the segment is omitted.

- ANSWERSET*n*, one for each answer set.

  If there is no answer set, the segment is omitted.

In IBM i, the metadata of a stored procedure that has an answer set will include column descriptions. These will appear as title fields in the synonym, as shown in the following example:

```
FILENAME=TEST_DESCRIPTIONS, SUFFIX=DB2 , $
  SEGMENT=INPUT, SEGTYPE=S0, $
    FIELDNAME=, ALIAS=DUMMY, USAGE=A1, ACTUAL=A1, MISSING=ON, $
  SEGMENT=ANSWERSET1, SEGTYPE=S0, PARENT=INPUT, $
    FIELDNAME=STORECODE, ALIAS=STORECODE, USAGE=A6, ACTUAL=A6,
      TITLE='Store,Code', $
    FIELDNAME=STORENAME, ALIAS=STORENAME, USAGE=A30, ACTUAL=A30,
      MISSING=ON, TITLE='Store,Name', $
    FIELDNAME=COUNTRY, ALIAS=COUNTRY, USAGE=A15, ACTUAL=A15,
      MISSING=ON, TITLE='Country', $
    FIELDNAME=REGION, ALIAS=REGION, USAGE=A25, ACTUAL=A25,
      MISSING=ON, TITLE='Region', $
```

Example: Synonym for Db2 Stored Procedure CustOrders

The following synonym describes a stored procedure, DB2SPR04 SP, with IN/OUT OUTPUT parameters.

```
FILENAME=SDB2SPR04, SUFFIX=DB2     , $
  SEGMENT=INPUT, SEGTYPE=S0, $
    FIELDNAME=PARM1, ALIAS=P0001, USAGE=I11, ACTUAL=I4,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM2, ALIAS=P0002, USAGE=I6, ACTUAL=I4,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM5, ALIAS=P0005, USAGE=YYMD, ACTUAL=DATE,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM6, ALIAS=P0006, USAGE=HHIS, ACTUAL=HHIS,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM7, ALIAS=P0007, USAGE=HYYMDm, ACTUAL=HYYMDm,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM11, ALIAS=P0011, USAGE=P17.5, ACTUAL=P8,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM13, ALIAS=P0013, USAGE=P20, ACTUAL=P10,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM15, ALIAS=P0015, USAGE=F9.2, ACTUAL=F4,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $
    FIELDNAME=PARM16, ALIAS=P0016, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, ACCESS_PROPERTY=(NEED_VALUE), $

  SEGMENT=OUTPUT, SEGTYPE=S0, PARENT=INPUT, $
    FIELDNAME=RETURN_CODE, ALIAS=P0000, USAGE=I11, ACTUAL=I4,
      MISSING=ON, TITLE='Return Code', $
    FIELDNAME=PARM1, ALIAS=P0001, USAGE=I11, ACTUAL=I4, MISSING=ON, $
    FIELDNAME=PARM2, ALIAS=P0002, USAGE=I6, ACTUAL=I4, MISSING=ON, $
    FIELDNAME=PARM3, ALIAS=P0003, USAGE=I11, ACTUAL=I4, MISSING=ON, $
    FIELDNAME=PARM4, ALIAS=P0004, USAGE=I6, ACTUAL=I4, MISSING=ON, $
    FIELDNAME=PARM5, ALIAS=P0005, USAGE=YYMD, ACTUAL=DATE, MISSING=ON, $
    FIELDNAME=PARM6, ALIAS=P0006, USAGE=HHIS, ACTUAL=HHIS,
      MISSING=ON, $
    FIELDNAME=PARM7, ALIAS=P0007, USAGE=HYYMDm, ACTUAL=HYYMDm,
      MISSING=ON, $
    FIELDNAME=PARM8, ALIAS=P0008, USAGE=YYMD, ACTUAL=DATE, MISSING=ON, $
    FIELDNAME=PARM9, ALIAS=P0009, USAGE=HHIS, ACTUAL=HHIS, MISSING=ON, $
    FIELDNAME=PARM10, ALIAS=P0010, USAGE=HYYMDm, ACTUAL=HYYMDm,
      MISSING=ON, $
    FIELDNAME=PARM11, ALIAS=P0011, USAGE=P17.5, ACTUAL=P8, MISSING=ON, $
    FIELDNAME=PARM12, ALIAS=P0012, USAGE=P17.5, ACTUAL=P8, MISSING=ON, $
    FIELDNAME=PARM13, ALIAS=P0013, USAGE=P20, ACTUAL=P10, MISSING=ON, $
    FIELDNAME=PARM14, ALIAS=P0014, USAGE=P20, ACTUAL=P10, MISSING=ON, $
    FIELDNAME=PARM15, ALIAS=P0015, USAGE=F9.2, ACTUAL=F4, MISSING=ON, $
    FIELDNAME=PARM16, ALIAS=P0016, USAGE=D20.2, ACTUAL=D8, MISSING=ON, $
    FIELDNAME=PARM17, ALIAS=P0017, USAGE=F9.2, ACTUAL=F4, MISSING=ON, $
    FIELDNAME=PARM18, ALIAS=P0018, USAGE=D20.2, ACTUAL=D8, MISSING=ON, $
```

Reference: Synonym Creation Parameters for Stored Procedures

The following list describes the synonym creation parameters for a stored procedure.

Object Type

Select *Stored Procedures*.

Owner/Schema and Object name (all platforms except IBM i)

Selecting these options adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the procedure names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all procedures whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Library

Object Name (IBM i)

To avoid the return of an extremely large and potentially unmanageable list, always supply a value for Library or Object Name:

- **Library.** Type a string for filtering the Library (or Db2 Collection), inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner IDs begin with the letters ABC; %ABC to select tables or views whose owner IDs end with the letters ABC; %ABC% to select tables or views whose owner IDs contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the table, view, or object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all tables, views, or objects whose names begin with the letters ABC; %ABC to select all tables, views, or objects whose names end with the letters ABC; %ABC% to select all tables, views, or objects whose names contain the letters ABC at the beginning, middle, or end.

Select

Select a procedure. You may only select one procedure at a time since each procedure will require unique input in the Values box on the next synonym creation pane.

Synonym Name

The name of the synonym, which defaults to the stored procedure name.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have stored procedures with identical names, assign a prefix or a suffix to distinguish their corresponding synonyms. Note that the resulting synonym name cannot exceed 64 characters.

If all procedures have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Creating a Report Against a Stored Procedure

You can report against a stored procedure's answer set using the same facilities you use to report against a database table:

- **SQL SELECT statement.** For syntax, see *How to Report Against a Stored Procedure Using SELECT* on page 530.
- **TABLE and GRAPH commands.** For syntax, see *How to Report Against a Stored Procedure Using the TABLE Command* on page 529.

When joining from or to a stored procedure answer set, you can:

- **Join from** only OUTPUT and ANSWERSET segments in a host file.
- **Join to** only INPUT segments in a cross-referenced file.

Syntax: How to Report Against a Stored Procedure Using the TABLE Command

To execute a stored procedure using the TABLE command, use the following syntax

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the stored procedure you want to execute.

parameter

Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, specify an asterisk (*). This displays a dummy segment, created when the synonym is generated, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters, or that there are no required parameters.

IF

Is an IF or WHERE keyword. Use this to pass a value to an IN parameter or an INOUT parameter in IN mode.

in-parameter

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

Note: The length of in-parameters cannot exceed 1000 characters if the adapter is configured for Unicode support.

value

Is the value you are passing to a parameter.

Syntax: How to Report Against a Stored Procedure Using SELECT

```
SQL
SELECT [parameter [,parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the stored procedure that you want to execute.

parameter

Is the name of a parameter whose values you want to display in the report. You can specify input parameters, output parameters, or input and output parameters.

If the stored procedure does not require parameters, enter an asterisk (*) in the syntax. This displays a dummy segment, created during synonym generation, to satisfy the structure of the SELECT statement.

`*`

Indicates that you want to display all indicated parameters, or that there are no required parameters.

`WHERE`

Is used to pass a value to an IN parameter or an INOUT parameter in IN mode. You must specify the value of each parameter on a separate line.

`in-parameter`

Is the name of an IN parameter, or INOUT parameter in IN mode, to which you want to pass a value.

`value`

Is the value you are passing to a parameter.

Customizing the Db2 Environment

The Adapter for Db2 provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Improving Response Time

The Adapter for Db2 on z/OS supports parallel processing if you issue the SET CURRENT DEGREE command prior to the request.

Syntax: **How to Improve Response Time**

```
ENGINE DB2 SET CURRENT DEGREE {'1'|'ANY'}
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`1`

Invokes serial processing. 1 is the default value.

ANY

Invokes parallel processing for dynamic requests. If the thread to Db2 is closed during the session, the value resets to 1.

Designating a Default Tablespace

You can use the SET DBSPACE command to designate a default tablespace for tables you create. For the duration of the session, the adapter places these tables in the Db2 tablespace that you identify with the SET DBSPACE command. If the SET DBSPACE command is not used, Db2 uses the default tablespace for the connected user.

Syntax: How to Designate a Default Storage Space for Tables

```
ENGINE DB2 SET DBSPACE {datasource.tablespace|DATABASE datasource}
```

where:

DB2

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

datasource

Is the data source name. DSNDB04 is the default value, which is a public data source.

tablespace

Is a valid table space name in the data source.

Note: This command will only affect CREATE FILE requests issued by Table Services. It does not affect Passthru CREATE TABLE commands.

On Linux, UNIX, and Windows, if you want to place a volatile or global temporary table in a user-created tablespace, issue the following command.

```
ENGINE DB2 SET DBSPACE usertemp
```

where:

usertemp

Is the name of a user temporary tablespace.

Note: When this setting is in effect, all tables created in the session will automatically be created in this tablespace. However, permanent tables cannot be placed in this type of tablespace and will result in an error. Therefore, you should not place this setting in any profile. You can add it to a procedure creates a temporary table. After the procedure executes, the setting will no longer be in effect.

Controlling the Types of Locks

You can use the SET ISOLATION command to specify the isolation level of transactions created by the adapter. The isolation level controls the types of locks for objects referenced in the requests executed within the transaction.

If you are working in the IBM i environment, see *Controlling Types of Locks on IBM i* on page 534 for OS-specific variations of SET ISOLATION syntax. For related information about another use for the SET ISOLATION syntax, see *Creating and Updating Db2 Files on IBM i* on page 535.

Syntax: How to Control the Lock Type

```
ENGINE DB2 SET ISOLATION level
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`level`

Sets the Db2 isolation level, which is mapped to the IBM RDBMS isolation level. If you do not specify an isolation level, the level is reset to the adapter default.

Db2 Isolation Level (CLI)	IBM RDBMS Isolation Level
RC (SQL_TXN_READ_COMMITTED)	CS (Cursor Stability)
SE (SQL_TXN_SERIALIZABLE_READ)	RR (Repeatable Read)
RR (SQL_TXN_REPEATABLE_READ)	RS (Read Stability)
RU (SQL_TXN_READ_UNCOMMITTED)	UR (Uncommitted Read)

Db2 Isolation Level (CLI)	IBM RDBMS Isolation Level
NC (SQL_TXN_NO_COMMIT)	Not applicable

- **RC.** Releases shared locks as the cursor moves on in the table. Use for read-only requests. RC is the default value. Maps to CS (Cursor Stability).
- **SE.** Locks the retrieved data until it is released by an SQL COMMIT WORK or SQL ROLLBACK WORK statement. Maps to RR (Repeatable Read).
- **RR.** Maps to RS (Read Stability). For more information, see the *Db2 Command and Utility Reference*.
- **RU.** Provides read-only access to records even if they are locked. However, these records may not yet be committed to the data source. Maps to UR (Uncommitted Read).
- **NC.** Commit and rollback operations have no effect on SQL statements. Any changes are effectively committed at the end of each successful change operation and can be immediately accessed. For more information, see *Creating and Updating Db2 Files on IBM i* on page 535 and the *Db2 Command and Utility Reference*.

Note:

- The adapter does not validate the isolation level values. If you issue the SET ISOLATION command with an invalid value, the adapter will not return a message.
- To display the isolation level setting, issue the ENGINE DB2 ? CONNECTINFO query command.

Reference: Controlling Types of Locks on IBM i

For the IBM i environment, the isolation level is preset to NC (no commit) so no action is required.

For a full IBM i installation, two forms of the SET ISOLATION command are supported: a long form that executes immediately in passthru mode, and a short form that is held until an actual SQL request is processed.

The two command variations are very similar, however, the short form, under an SQL adapter configuration (rather than a CLI configuration), generates the following Db2 message in the IBM i system process log if a COMMIT, ROLLBACK, or SAVEPOINT command is issued before any real work is done (possibly due to an AUTOCOMMIT command):

```
SQL7007: COMMIT, ROLLBACK, or SAVEPOINT not valid
```

The syntax variations are:

Short Form

```
ENGINE DB2 SET ISOLATION level
```

Long Form

```
ENGINE DB2 SET TRANSACTION ISOLATION LEVEL level
```

Standard options for *level* apply (see *How to Control the Lock Type* on page 533). However, the instruction to display the current isolation level by issuing the following query command applies only for the *short form* setting:

```
ENGINE DB2 ? CONNECTINFO
```

There is no way to display the current long form setting.

Reference: Creating and Updating Db2 Files on IBM i

The following information applies to HOLD FORMAT DB2 and procedures that update a Db2 object in a non-journaled collection.

While Db2 on IBM i supports CREATE TABLE operations to a non-journaled collection (a library with no journal receivers), Db2 normally considers this a commitment control error and issues an error message. When a HOLD FORMAT DB2 command is issued, the same error condition triggers an error message to the adapter. In response, the adapter creates the table, but does not perform the load step. However, if the server is configured with Db2 as a CLI-based adapter, you can use the ISOLATION setting of NC (No Commit) to prevent Db2 from triggering the error message, thereby enabling the table to load.

You can set ISOLATION to NC on a request-by-request basis before issuing HOLD FORMAT DB2:

```
SQL DB2 SET ISOLATION NC
```

Alternatively, you can set the NC option server wide from the Adapter for Db2's Change Settings pane. (To access this pane, click *Adapters* on the menu bar, right-click the name of the configured adapter, and choose *Change Settings* from the menu.)

After completing this task, revert to the original ISOLATION setting, if appropriate.

Note: An error message like the following will be generated if you issue a HOLD FORMAT DB2 ... DROP command but do not have the authority to DROP an existing file.

```
(FOC1400) SQLCODE IS -601 (HEX: FFFFFDA7): [42710] ABC in XYZ type *FILE
already exists.
```

```
(FOC1414) EXECUTE IMMEDIATE ERROR.
```

- If you receive this message, make sure that you have DB2 DROP/CREATE authority and reissue the command.
- When connecting from a non-IBM i platform through a local Db2 client, the SET isolation does not work. You can use the following specific platform syntax.

Note:

- **From a Windows platform:**

  Add a CLI parameter *TxnIsolation* with the value *32* within your ODBC settings under *Administrative Tools*.

- **From a Unix/Linux platform:**

  You can run the following Db2 command on your database:

  ```
  DB2 update CLI CFG for section <tablename> using TxnIsolation 32
  ```

  Verify these settings with the following command:

  ```
  DB2 get CLI CFG
  ```

  As an SQL alternative (not OS-specific), you can add `WITH NONE` to the end of your SQL UPDATE command.

Overriding Default Parameters for Index Space

You can use the SET IXSPACE command to override the default parameters for the index space implicitly created by the CREATE FILE and HOLD FORMAT commands.

Syntax: How to Set IXSPACE

```
ENGINE DB2 SET IXSPACE [index-spec]
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

index-spec

Is the portion of the DB2 CREATE INDEX statement that defines the parameters for the index. It can consist of up to 94 bytes of valid Oracle index space parameters. To reset the index space parameters to their default values, issue the SET IXSPACE command with no parameters.

Note: Refer to the Db2 documentation for more information on this command.

The long form of SQL Passthru syntax for commands exceeding one line is:

```
ENGINE DB2
SET IXSPACE index-spec
END
```

For example, to specify the NOSORT, NOLOGGING, and TABLESPACE portions of the DB2 CREATE INDEX statement, enter the following commands:

```
ENGINE DB2
SET IXSPACE NOSORT NOLOGGING
TABLESPACE TEMP
END
```

Note: This command will only affect CREATE INDEX requests issued by CREATE FILE and HOLD FORMAT DB2 commands. It does not affect Passthru CREATE INDEX commands, for example:

```
ENGINE DB2 SET IXSPACE TABLESPACE tablespace_name
TABLE FILE table_name
PRINT *
ON TABLE HOLD AS file_name FORMAT DB2
END
```

Activating NONBLOCK Mode

The Adapter for Db2 has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Setting*s from the menu. The Change Settings pane opens.

Note: This setting is not supported for the z/OS Unified Server Db2 CAF Adapter (all deployment modes).

Syntax: How to Activate NONBLOCK Mode

```
ENGINE DB2 SET NONBLOCK {0|n}
```

where:

DB2

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
- Kill Session button on the Web Console is pressed.

Note: A value of 1 or 2 should be sufficient for normal operations.

Controlling Column Names

You can use the SET NOCOLUMNTITLE command to control the column names in a report when executing a stored procedure.

Syntax: How to Control Column Names

```
ENGINE DB2 SET NOCOLUMNTITLE {ON|OFF}
```

where:

DB2

Indicates the adapter. You can omit this parameter value if you previously issued the SET SQLENGINE command.

ON

Uses generated column names (for example, E01, E02, and so on) instead of the column names returned by Db2.

OFF

Uses the column names returned by Db2. OFF is the default value.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE DB2 SET PASSRECS {ON|OFF}
```

where:

DB2

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Note: This behavior applies for all supported versions of Db2 up to Version 9 on all platforms. In Db2 Version 9 on z/OS, the PASSRECS command does not provide a row count for mass DELETE operations (that is, DELETE statements without a WHERE clause). However, you can obtain a row count in this situation by adding a WHERE phrase to your report request. For example, the following request would generate a delete count:

```
SQL DB2
DELETE FROM DB2TAB WHERE F1=15;
END
FOC1364) ROWS AFFECTED BY PASSTHRU COMMAND: 1/DELETE
```

Setting End-User Information

In the UNIX and Windows Reporting Server environment, you can set values for end-user information to be passed to a Db2 server when the next SQL request is processed. This information includes the:

- Client user ID
- Application program name
- Workstation name
- Accounting string

You can then query the information using SELECT statements.

Note: For a Db2 server on z/OS, you can also set the end-user information but only from a UNIX or Windows server connecting to a Db2 on z/OS.

Syntax: How to Set End-User Information

```
ENGINE DB2 SET CLIENT_APPLNAME application_name
ENGINE DB2 SET CLIENT_USERID userid
ENGINE DB2 SET CLIENT_WRKSTNNAME workstation
ENGINE DB2 SET CLIENT_ACCTNG account
```

where:

application_name

Is the name of an application program.

userid

Is the user ID of a client.

workstation

Is the name associated with the user workstation.

account

Is an accounting string associated with the client user.

Syntax: How to Query End-User Information

In the UNIX and Windows Reporting Server environment, depending on where the Db2 server is running, the end-user information can be queried using the syntax below.

If the Db2 server is on UNIX or Windows:

```
ENGINE DB2
SELECT CLIENT APPLNAME, CLIENT USERID, CLIENT WRKSTNNAME, CLIENT ACCTNG
FROM SYSIBM.SYSDUMMY1;
END
```

If the Db2 server is on z/OS:

```
ENGINE
DB2  SELECT CURRENT CLIENT_APPLNAME,CURRENT CLIENT_USERID,CURRENT
CLIENT_WRKSTNNAME, CURRENT CLIENT_ACCTNG  FROM SYSIBM.SYSDUMMY1;
END
```

Note: Natively on z/OS, you can also view end-user information by using spufi to submit the following command:

```
-DISPLAY THREAD(*) DETAIL
```

Setting Naming Conventions

Controls the separator character used for interpreting multipart table, view, and RPC names. This option is typically used to allow a request coded with "." as the separator to be run on systems that use "/" as the separator (for example, IBM i).

This setting is only valid for use with a server configured as CLI. (This applies to most platforms, including IBM i if so configured). If the server needs to support both naming conventions, you can configure an additional service block with a service block profile that uses the desired naming setting and sends requests to the desired block.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

Syntax: How to Set Naming Conventions

The available parameters are:

```
ENGINE DB2 SET NAMING {SQL|SYS}
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`SQL`

Standard "." character is used as separator in multipart table names.

SYS

System "/" character is used as separator in multipart table names.

Controlling HOLD DBMS Creation

An extension of the HOLD AS *app/name* FORMAT DB2 syntax enables you to exercise more precise control over the creation of HOLD DBMS files.

Syntax: How to Control DBMS Creation

```
HOLD AS app/name FORMAT DB2 [TABLENAME dbms_name][CONNECTION conn_name]
  [DROP]
```

where:

dbms_name

Is the DBMS table to create. It may be a one, two, or three part name, using the separator appropriate to the DBMS (typically "." (dot)).

For IBM i, a "/" (slash) is the separator, unless the SET NAMING SQL command is being used to reset the separator character.

Note: For Db2 running on IBM i, if the TABLENAME parameter and value are omitted, the default location for the resulting table is the user's default login library. This applies to adapters configured for SQL and CLI.

conn_name

Is the DBMS connection name. When multiple DBMS connections have been configured and are in use, conn_name specifies which connection to use.

DROP

Drops the table before creation. This option enables you to delete either a known table or one that was created and stored in a temporary space when persistValue=*global_temporary*. Without the DROP option, if a table already exists, an error occurs when the table is created, resulting in failure to load the table.

If no table exists, this option is ignored.

Db2 Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109 and *Optimizing Requests to Pass Virtual Fields Defined as Constants* on page 112.

Optimizing Non-Equality WHERE-Based Left Outer Joins

A left outer join selects all records from the host table and matches them with records from the cross-referenced table. When no matching records exist, the host record is still retained, and default values (blank or zero) are assigned to the cross-referenced fields. The adapter can optimize any WHERE-based left outer join command in which the conditional expression is supported by the RDBMS.

Syntax: How to Specify a Conditional Left Outer JOIN

```
JOIN LEFT_OUTER FILE hostfile AT hfld1 [TAG tag1]
     [WITH hfld2]
     TO {UNIQUE|MULTIPLE}
     FILE crfile AT crfld [TAG tag2] [AS joinname]
     [WHERE expression1;
     [WHERE expression2;
     ...]

END
```

where:

`LEFT_OUTER`

Specifies a left outer join. If you do not specify the type of join in the JOIN command, the ALL parameter setting determines the type of join to perform.

`hostfile`

Is the host Master File.

`AT`

Links the correct parent segment or host to the correct child or cross-referenced segment. The field values used as the AT parameter are not used to cause the link. They are used as segment references.

`hfld1`

Is the field name in the host Master File whose segment will be joined to the cross-referenced data source. The field name must be at the lowest level segment in its data source that is referenced.

`tag1`

Is the optional tag name that is used as a unique qualifier for fields and aliases in the host data source.

`WITH hfld2`

Is a data source field with which to associate a DEFINE-based conditional JOIN. For a DEFINE-based conditional join, the KEEPDEFINES setting must be ON, and you must create the virtual fields before issuing the JOIN command.

`MULTIPLE`

Specifies a one-to-many relationship between *from_file* and *to_file*. Note that ALL is a synonym for MULTIPLE.

`UNIQUE`

Specifies a one-to-one relationship between *hostfile* and *crfile*. Note that ONE is a synonym for UNIQUE.

Note: Unique returns only one instance and, if there is no matching instance in the cross-referenced file, it supplies default values (blank for alphanumeric fields and zero for numeric fields).

The unique join is a WebFOCUS concept. The RDBMS makes no distinction between unique and non-unique situations; it always retrieves all matching rows from the cross-referenced file.

If the RDBMS processes a join that the request specifies as unique, and if there are, in fact, multiple corresponding rows in the cross-referenced file, the RDBMS returns all matching rows. If, instead, optimization is disabled so that WebFOCUS processes the join, a different report results because WebFOCUS, respecting the unique join concept, returns only one cross-referenced row for each host row.

crfile

Is the cross-referenced Master File.

crfld

Is the join field name in the cross-referenced Master File. It can be any field in the segment.

tag2

Is the optional tag name that is used as a unique qualifier for fields and aliases in the cross-referenced data source.

joinname

Is the name associated with the joined structure.

expression1, expression2

Are any expressions that are acceptable in a DEFINE FILE command. All fields used in the expressions must lie on a single path.

Reference: Conditions for WHERE-Based Outer Join Optimization

- In order for a WHERE-based left outer join to be optimized, the expressions must be optimizable for the RDBMS involved and at least one of the following conditions must be true:
  - The JOIN WHERE command contains at least one *field1* EQ *field2* predicate in which *field1* is in *table1* and *field2* is in *table2*.

    or
  - The right table has a key or a unique index that does not contain NULL data.

    or
  - The right table contains at least one "NOT NULL" column that does not have a long data type (such as TEXT or IMAGE).
- The adapter SQLJOIN OUTER setting must be ON (the default).

Example: Optimizing a Non-Equality Left-Outer Join

The following request creates a left outer conditional join between two Db2 data sources and reports against the joined data sources. The STMTRACE is turned on in order to view the SQL generated for this request:

```
SET TRACEUSER = ON
SET TRACEOFF = ALL
SET TRACEON = STMTRACE//CLIENT
JOIN LEFT_OUTER FILE baseapp/EQUIP AT CARS
TO ALL FILE baseapp/CARREC AT CARC
WHERE CARS NE CARC;
END
TABLE FILE baseapp/EQUIP
PRINT CARS CARC STANDARD
BY MODEL
END
```

The WebFOCUS request is translated to a single DB2 SELECT statement that incorporates the left outer join, and the non-equality condition is passed to the RDBMS in the ON clause:

```
SELECT T1."CARS"(CHAR( 16)),T1."STANDARD"(CHAR( 40)),
T2."CARC"(CHAR( 16)),T2."MODEL"(CHAR( 24)) FROM ( EQUIP T1 LEFT
OUTER JOIN CARREC T2 ON (T1."CARS" <> T2."CARC") ) ORDER BY
T2."MODEL";
```

Specifying the Block Size for Retrieval Processing

The Adapter for Db2 supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

Syntax: How to Specify Block Size for Array Retrieval

The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

```
ENGINE DB2 SET FETCHSIZE n
```

where:

`DB2`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is the number of rows to be retrieved at once using array retrieval techniques for the CLI adapter or a cursor with Rowset positioning and multi row Fetch for the CAF adapter. Accepted values are 1 to 32000. The default is 100. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.

Syntax: How to Specify Block Size for Insert Processing

In combination with LOADONLY, the block size for an INSERT applies to MODIFY INCLUDE requests. INSERTSIZE is also supported for parameterized DIRECT SQL INSERT statements.

```
ENGINE DB2 SET INSERTSIZE n
```

where:

DB2

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is the number of rows to be inserted using array insert techniques. Accepted values are 1 to 5000. 1 is the default value. If the result set contains a column that has to be processed as a BLOB, the INSERTSIZE value used for that result set is 1.

Syntax: How to Suppress the Bulk Insert API

```
ENGINE DB2 SET FASTLOAD [ON|OFF]
```

where:

DB2

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Uses the Bulk Insert API. ON is the default.

OFF

Suppresses the use of the Bulk Insert API.

Reference: Bulk Insert API Behavior

You can use DataMigrator with the Bulk Insert API for Db2 (Windows and UNIX).

Errors that occur during the load (such as duplication) can cause the batch of rows to be rejected as a whole.

Improving Efficiency With Aggregate Awareness

Aggregate awareness substantially improves the efficiency of queries.

For details about this feature, see *Aggregate Awareness Support* on page 2693.

Syntax: How to Set Aggregate Awareness

```
SET AGGREGATE_AWARENESS {FRESH_ONLY|OLD_OK|OFF}
```

where:

FRESH_ONLY

Sets different values for the parameters associated with each RDBMS.

OLD_OK

Sets different values for the parameters associated with each RDBMS.

OFF

If no option is selected, the behavior of the target RDBMS is determined by the database configuration options. There is no default for this setting.

For details about adapter-specific settings, see *Usage Notes for Aggregate Awareness* on page 2694.

Using Db2 Cube Views

The Adapter for Db2 supports Cube Views as an object type. You can specify Cubes as the object type for which you want to create synonyms.

Before you can use the Adapter for Db2 with Cube Views, you must define Db2 connections for the database(s) containing the Db2 cube views.

For details, see *Creating Synonyms* on page 512.

Mapping Metadata for Db2 Cubes Views

Synonyms are generated for Cubes (not Cube Models). These synonyms reflect the structure of the cube and its attributes and measures, rather than the structure of the underlying Db2 tables and their columns.

The Master File synonym component has several segments:

- The root segment corresponds to the Cube Facts.
- The children segments correspond to the Cube Hierarchies.

The fields in the root segment reflect the Cube Measures. Field names and titles are generated based on measure business names, while aliases are generated based on measure names.

- The PROPERTY attribute for these fields contains the word Measure (or Calculated Measure for calculated measures).
- The REFERENCE attribute contains the aggregated expression for measures that are based on simple columns (not expressions) and have aggregations that match those available in the DML.

Example: Sample Db2 Cube View Master File

```
FILENAME=BASEAPP/COMPLEX_MEASURES__C_, SUFFIX=DB2CV   , $
  SEGMENT=SALESCF, SEGTYPE=S0, $
    FIELDNAME=4ADDS, ALIAS=4adds, USAGE=I11, ACTUAL=I4, MISSING=ON,
      TITLE='4adds', REFERENCE=CNT.4ADDS, PROPERTY=MEASURE,  $
    FIELDNAME=POWEROFADDS, ALIAS=powerofadds, USAGE=D21.2, ACTUAL=D8,
      MISSING=ON, TITLE='powerofadds', PROPERTY=MEASURE,  $
    FIELDNAME=PROFIT_CONST, ALIAS=profit*const, USAGE=D21.2, ACTUAL=D8,
      MISSING=ON, TITLE='profit*const', PROPERTY=MEASURE,  $
    FIELDNAME=RANDOM, ALIAS=random, USAGE=I11, ACTUAL=I4, MISSING=ON,
      TITLE='random', REFERENCE=CNT.RANDOM, PROPERTY=MEASURE,  $
    FIELDNAME=3_COLS_WITH_MIXTUREOF_FUNC,
      ALIAS='3 cols with mixtureof FUNC', USAGE=D21.2, ACTUAL=D8,
      MISSING=ON, TITLE='3 cols with mixtureof FUNC',
      PROPERTY=MEASURE,  $
    FIELDNAME=ROUND_OF_ANOTHER_MEAS, ALIAS='round of another meas',
      USAGE=D21.2, ACTUAL=D8, MISSING=ON, TITLE='round of another meas',
      PROPERTY=MEASURE,  $

  SEGMENT=PRODUCT__CH_, SEGTYPE=U, PARENT=SALESCF, $
    FIELDNAME=PRODUCT_GROUP_ID, ALIAS=product_group_ID, USAGE=I11,
      ACTUAL=I4, MISSING=ON, TITLE='product_group_ID',
      WITHIN='*product (CH)', $
    FIELDNAME=PRODUCT_LINE_ID, ALIAS=product_line_ID, USAGE=I11, ACTUAL=I4,
      MISSING=ON, TITLE='product_line_ID', WITHIN=PRODUCT_GROUP_ID, $
    FIELDNAME=PRODUCT_LINE_NAME,
      ALIAS='12  product_line_ID   product_line_name', USAGE=A25V,
      ACTUAL=A25V, MISSING=ON, TITLE='product_line_name',
      REFERENCE=PRODUCT_LINE_ID, PROPERTY=CAPTION,  $

  SEGMENT=STORE__CH_, SEGTYPE=U, PARENT=SALESCF, $
    FIELDNAME=STORE_LOCATION_ID, ALIAS='**** store_location_ID_1',
      USAGE=I11, ACTUAL=I4, MISSING=ON, TITLE='store_location_ID',
      WITHIN='*store (CH)', $
    FIELDNAME=STORE_ADDRESS,
      ALIAS='store_location_ID_1   _store_address', USAGE=A25V,
      ACTUAL=A25V, MISSING=ON, TITLE='store address',
      REFERENCE=STORE_LOCATION_ID, PROPERTY=UDA,  $
    FIELDNAME=STORE_CITY, ALIAS='store_location_ID_1   _store_city',
      USAGE=A45, ACTUAL=A45, MISSING=ON, TITLE='store_city',
      REFERENCE=STORE_LOCATION_ID, PROPERTY=UDA,  $
    FIELDNAME=STORE_ID, ALIAS=store_ID, USAGE=I11, ACTUAL=I4, MISSING=ON,
      TITLE='store_ID',WITHIN=STORE_LOCATION_ID, $
```

Calling a Db2 Stored Procedure Using SQL Passthru

Db2 stored procedures are supported using SQL Passthru. These procedures need to be developed within Db2 using the CREATE PROCEDURE command.

The adapter supports stored procedures with IN, OUT, and INOUT parameters.

The output parameter values that are returned by stored procedures are available as result sets. These values form a single-row result set that is transferred to the client after all other result sets are returned by the invoked stored procedure. The names of the output parameters (if available) become the column titles of that result set.

Note that only the output parameters (and the returned value) referenced in the invocation string are returned to the client. As a result, users have full control over which output parameters have their values displayed.

The server supports invocation of stored procedures written according to the rules of the underlying DBMS. Note that the examples shown in this section are SQL-based. See the DBMS documentation for rules, languages, and additional programming examples.

Syntax: How to Invoke a Stored Procedure

```
SQL DB2 EX procname [parameter_specification1]
[,parameter_specification2]...
END
```

where:

`DB2`

Is the ENGINE suffix for Db2.

`procname`

Is the name of the stored procedure. It is the fully or partially qualified name of the stored procedure in the native RDBMS syntax.

You can employ either SQL or SYS naming conventions to control the separator character used for interpreting multipart names, as described in *Setting Naming Conventions* on page 541.

`parameter_specification`

IN, OUT, and INOUT parameters are supported. Use the variation required by the stored procedure:

`IN`

Is a literal (for example, 125, 3.14, 'abcde'). You can use reserved words as input. Unlike character literals, reserved words are not enclosed in quotation marks (for example, NULL). Input is required.

OUT

Is represented as a question mark (?). You can control whether output is passed to an application by including or omitting this parameter. If omitted, this entry will be an empty string (containing 0 characters).

INOUT

Consists of a question mark (?) for output and a literal for input, separated by a slash: /. (For example: ?/125, ?/3.14, ?/'abcde'.) The out value can be an empty string (containing 0 characters).

Example: Invoking a Stored Procedure

Note that this sample employs the SQL naming convention, where the "." character is used as the separator in multipart table names. If your site uses the SYS[TEM] naming convention (typical in IBM i environments), the "/" character is used as a separator in multipart table names. In this case, adjust the separator character as needed to conform to the SYS naming convention. For details, see *Setting Naming Conventions* on page 541.

In this example, a user invokes a stored procedure, edaqa.test_proc01, supplies input values for parameters 1, 3, 5 and 7, and requests the returned value of the stored procedure, as well as output values for parameters 2 and 3.

Note that parameters 4 and 6 are omitted; the stored procedure will use their default values, as specified at the time of its creation.

```
SQL DB2 EX edaqa.test_proc01 125,?,?/3.14,,'abc',,'xyz'
END
```

Example: Sample Stored Procedure

Note that this sample employs the SQL naming convention, where the "." character is used as the separator in multipart table names. If your site uses the SYS[TEM] naming convention (typical in IBM i environments), the "/" character is used as a separator in multipart table names. In this case, adjust the separator character as needed to conform to the SYS naming convention. For details, see *Setting Naming Conventions* on page 541.

This stored procedure uses out and inout parameters:

```
CREATE PROCEDURE EDAQA.PROCP3 (   OUT chSQLSTATE_OUT   CHAR(5),
                                  OUT intSQLCODE_OUT   INT,
                                  INOUT l_name char(20),
                                  INOUT f_name char(20))
    RESULT SETS 1
    LANGUAGE SQL
-------------------------------------------------------------------------
-- SQL Stored Procedure
-------------------------------------------------------------------------
P1: BEGIN
    -- Declare variable
    DECLARE SQLSTATE CHAR(5) DEFAULT '00000';
    DECLARE SQLCODE INT DEFAULT 0;
    -- Declare cursor
    DECLARE cursor1 CURSOR WITH RETURN FOR
        SELECT
           EDAQA.NF29005.SSN5 AS SSN5,
           EDAQA.NF29005.LAST_NAME5 AS LAST_NAME5,
           EDAQA.NF29005.FIRST_NAME5 AS FIRST_NAME5,
           EDAQA.NF29005.BIRTHDATE5 AS BIRTHDATE5,
           EDAQA.NF29005.SEX5 AS SEX5
        FROM
           EDAQA.NF29005
        WHERE
           (
             ( EDAQA.NF29005.LAST_NAME5 =  l_name )
        AND
             ( EDAQA.NF29005.FIRST_NAME5 = f_name )
           );
     -- Cursor left open for client application
    OPEN cursor1;
    SET chSQLSTATE_OUT = SQLSTATE;
    SET intSQLCODE_OUT = SQLCODE;
    SET l_name = 'this is first name';
    SET f_name = 'this is last name';
END P1   @
```

Chapter 20

Using the Adapter for DB Heritage Files

The Adapter for DB Heritage Files allows applications to access and read native IBM i data sources (also known as Physical, Logical, and Multi-format logical data base files) using the Open Query Facility (OPNQRYF). The adapter converts application requests into native OPNQRYF statements and returns optimized answer sets to the requesting application. All physical, logical, and multi-format formats are supported.

Note: In previous releases, this adapter was called DBFILE or DB File.

In this chapter:

Preparing the DB Heritage Files Environment

The Adapter for DB Heritage Files does not require setting any environment variables.

Configuring the Adapter for DB Heritage Files

You can configure the Adapter for DB Heritage Files from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter for DB Heritage Files

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note: The *DB Heritage Files* adapter is under the *Sequential and Indexed* group folder. No input parameters are required.

Managing DB Heritage Files Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the DB Heritage Files data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each DB Heritage Files file or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server metadata.

Note: Refer to *DB Heritage Standard Master File Attributes* on page 558, if you wish to review general information about Master File attributes, create a synonym based on attributes other than a standard DDS data definition, or make manual adjustments to synonyms generated using graphical tools.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Reference: Synonym Creation Parameters for DB Heritage Files

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Select Files

Choose the type of file you wish to see from the following options: All, Physical, or Logical. (At this level, there is no differentiation between logical and multi-format logical.)

Library Name

Supply the name of the library in which the physical and/or logical files reside. (Wildcards are not permitted.)

Note: When you create a synonym for DB Heritage Files on the IBM i platform, standard IBM i naming conventions apply to the target data source. Therefore, the Adapter for DB Heritage Files supports the use of double-quotation marks around any library name and/or file name that contains lower case or NLS characters.

Filter by Name

If you wish to limit retrieval, enter a full file name or a partial name with a wildcard symbol % in the Filter by Name input box. A full name returns just that entry. A name with a wildcard symbol may return many entries.

Use text description as field name

Click this check box to use descriptive text from title fields as more meaningful field names in the synonym.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Select objects for synonym creation

To select all member names in the list, select the check box to the left of the *Default Synonym Name* column heading. (If the library contains a large number of files, this check box will not appear, however, synonyms will be created for all files automatically.)

To select specific member names, click the corresponding check boxes.

Not all listed objects are data-related. Be sure to select those that are appropriate for creating synonyms.

Note: Mixed-case names or names with NLS character will appear in double quotation marks. However, the double quotation marks will be replaced by underscore characters in the Default Synonym Name column.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Note: If you see a synonym name surrounded by underscore characters (as described in the previous note), you can remove the underscores if you wish.

Example: Creating a Synonym for a DB Heritage Files Data Source

In this example, the field attributes from the original file initialization are used in the new metadata. (For related information about file initialization, see *DB Heritage Standard Master File Attributes* on page 558.

An internal field (RECFORM) is also automatically added to reference a particular record's format. The RECFORM ALIAS always has a value of the name of the record format and is always added (even for single format files).

To generate the following synonym from the Create Synonym panes:

1. Specify *SHIPPING* in the Library Name field, then click *Submit*.
2. On the second Create Synonym pane, choose the member name *DBF2901* from the list of objects that comprise the library and click *Create Synonym*.

   The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: All Synonyms Created Successfully
3. From the message window, click *Applications* on the menu bar.
4. Open the baseapp application folder in the navigation pane and right-click the synonym *DBF2901*.
5. Select *Edit as Text* from the drop-down menu to view the generated Master File. Your selections are reflected in the DATASET field, prefixed with QSYS:

   Generated Master File:

```
FILENAME=DBF2901, SUFFIX=DBFILE  ,
 DATASET=QSYS:SHIPPING/DBF2901, $
  SEGMENT=DBF2901, SEGTYPE=S0, $
    FIELDNAME=CCODE1, ALIAS=COUNTRY_COD1, USAGE=A5, ACTUAL=A5,
      TITLE='COUNTRY_COD1', DESCRIPTION='Country Code Number 1', $
    FIELDNAME=CNAME1, ALIAS=COUNTRY_NAM1, USAGE=P16, ACTUAL=P8,
      TITLE='COUNTRY_NAM1', DESCRIPTION='Country Name Number 1', $
    FIELDNAME=RECFORM, ALIAS=DBF2901, USAGE=A10, ACTUAL=A10, $
```

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

DB Heritage Standard Master File Attributes

Traditional IBM i applications, such as RPG, use Data Description Specification (DDS) files to initialize data files (also known as native database files) with header information about fields, data types, sizes and, optionally, aliases (ALIAS), column headings (COLHDG), descriptive comments (TEXT), and other information such as keys.

The features of the DDS have remained essentially stable despite the advent on IBM i of newer languages, such as C and COBOL, and their associated features. For example, while COBOL file descriptions may contain OCCURS statements, DDS does not support OCCURS clauses; for DDS purposes, separate fields must be used to handle this construct.

For DB Heritage Files, the IBM i DSPFFD command is used to extract the DDS information that is initialized into a data file at synonym-creation time, generating a complete set of metadata. However, in some instances, applications can redefine the use of the DDS information drastically, unbeknownst to the DSPFFD tool since the header information remains unchanged. This might occur, for example, in a COBOL application that has a common set of keys, part of which is a rectype that is used to redefine the remainder of the record into any number of layouts. The presence of the common set of keys suggests that the application is writable, when, in fact, DB Heritage Files is a Read-only adapter. While this situation does not generally occur, if it does you can avoid problems by following these guidelines to define proper metadata:

- Keep in mind that the Adapter for DB Heritage Files is *Read only*. Although some of the descriptive information may give the impression that describing keys is required and would provide Write capability, that is, in fact, *not* the case.
- Although the Adapter for DB Heritage Files is not a read/write adapter, you can use it in conjunction with the Adapter for Db2, which is a read/write adapter. Db2 itself provides an automatic feature for reading and writing native database files, with the exception of multi-format logical files, dynamically by using DSPFFD information on the fly. Thus, WebFOCUS can read and write DB Heritage Files data if the Adapter for Db2 is used to access the data. This two-adapter method enables you to take advantage of features of each one:
  - Adapter for Db2 read/write capabilities.
  - Adapter for DB Heritage Files support of Multi-Format Logical files and faster processing capabilities for large quantities of records.

  Tip: You can set up metadata for both methods and switch between them based upon the needs of your application.
- If a COBOL FD is available, you can use it with the Adapter for Flat Files to generate metadata with a SUFFIX=FIX value. You can then change the SUFFIX to DBFILE and add the DATASET= *value*.

For related information about DSPFFD, see *DSPFFD Behavior* on page 561.

Reference: Standard Master File Attributes for DB Heritage Files

Most standard Master File attributes are used with DB Heritage Files data sources in the standard way.

- **FILENAME.** The FILENAME attribute is the logical name of the file. It typically matches the Master File name.

- **SUFFIX.** The SUFFIX attribute in the declaration has the value DBFILE to indicate that access is for DB Heritage Files.
- **DATASET.** The DATASET attribute in the declaration indicates the default file to access. This attribute is optional and may be overridden by a FILEDEF command issued before a TABLE request (for example, in a focexec). The attribute value is preceded by the text *QSYS:*, which indicates that the file is a library (rather than a two-part application name). The syntax is:

  ```
  QSYS:[library/]file[(member)]
  ```

  If the library is not supplied, the user's library path is used to locate the file.
- **SEGNAME.** The SEGNAME attribute of the first or root segment in a Master File for a DB Heritage Files data source must be ROOT. The remaining segments can have any valid segment name.

  The only exception involves unrelated RECTYPEs, where the root SEGNAME must be DUMMY.

  All non-repeating data goes in the root segment. The remaining segments may have any valid name from one to eight characters.

  Any segment except the root is the descendant, or child, of another segment. The PARENT attribute supplies the name of the segment that is the hierarchical parent or owner of the current segment. If no PARENT attribute appears, the default is the immediately preceding segment. The PARENT name may be one to eight characters.
- **SEGTYPE.** The SEGTYPE attribute should be S0 for DB Heritage Files data sources.
- **GROUP.** The keys of a DB Heritage Files data source are defined in the segment declarations as GROUPs consisting of one or more fields.
- **FIELD.** The field names in the DB Heritage Files, along with the descriptive attributes, ALIAS, USAGE, and ACTUAL. For related information, see *USAGE and ACTUAL Values in DB Heritage Files* on page 560.

Reference: USAGE and ACTUAL Values in DB Heritage Files

Synonyms for DB Heritage Files will pick up certain additional data attributes which may have been declared in the DDS information that was used when the original data file was created.

For example, in a monetary declaration such as a dollar sign ($), if the IBM i system value for QCURSYN is the same as the symbol used in the DDS declaration, then the Master File *M* attribute (floating monetary symbol) is used. In this situation, the actual symbol that is displayed depends on the value defined by the SET CURRSYN command (dollar sign, by default), which may be set in an application or in a profile.

However, if the values for QCURSYN and the monetary sign in the DDS information do not match, but the DDS monetary value is defined as dollar, pound, euro, or yen, then !D, !L, !E, or !Y are displayed regardless of the value of CURRSYN on the assumption that the application is intentionally using multiple monetary symbols.

On the other hand, if QCURSYN and the monetary sign in the DDS information do not match and the DDS monetary value is not set to dollar, pound, euro, or yen, then the M symbol is displayed since dollar, pound, euro, and yen are the only explicitly supported characters for reports with mixed monetary symbols.

Among the other data attributes that may be picked up from the DDS information are date and time fields and the following symbols: *c* (suppresses commas), *C* (inserts a comma after every third significant digit, or a period instead of a comma if continental decimal notation is in use), R (places CR after negative numbers).

Reference: DSPFFD Behavior

The DSPFFD field name value is used as the ALIAS=*value,* and the DSPFFD alias value is used as the FIELDNAME=*value*. This ensures that DSPFFD aliases, which can be too long to use as ALIAS values when creating synonyms in a hub/sub server configuration, are within the required character limit for hub/sub aliases.

While you may wish to refresh existing DB Heritage synonyms for other reasons, there is no explicit need to do so unless the underlying DSPFFD information actually changes. Existing DB Heritage related procedures will continue to run, with one possible difference. Report column titles, and possibly associated column widths, will display differently, if the request:

- Uses recreated metadata.
- Includes different values for FIELDNAME and ALIAS. (Frequently, these values are the same in the Master File.)
- Does not specify a TITLE value in the metadata.
- Does not assign explicit column titles.

Describing a Group Field

A single-segment data source may have only one key field, but it must still be described with a GROUP declaration. The group must have ALIAS=KEY.

Groups can also be assigned simply to provide convenient reference names for groups of fields. Suppose that you have a series of three fields for an employee: last name; first name; and middle initial. You use these three fields consistently to identify the employee. You can identify the three fields in your Master File as a GROUP named EMPINFO. Then, you can refer to these three linked fields as a single unit, called EMPINFO. When using the GROUP feature for non-keys, the parameter ALIAS= must still be used, but should not equal KEY.

For group fields, you must supply both the USAGE and ACTUAL formats in alphanumeric format. The length must be exactly the sum of the subordinate field lengths.

The GROUP declaration USAGE attribute specifies how many positions to use to describe the key in the data source. If a Master File does not completely describe the full key at least once, the following warning message appears:

```
(FOC1016) INVALID KEY DESCRIPTION IN MASTER FILE
```

The cluster key definition is compared to the Master File for length and displacement.

When you expand on the key in a RECTYPE data source, describe the key length in full on the last non-OCCURS segment on each data path.

Do not describe a group with ALIAS=KEY for OCCURS segments.

If the fields that make up a group key are not alphanumeric fields, the format of the group key is still alphanumeric, but its length is determined differently. The ACTUAL length is still the sum of the subordinate field lengths. However, the USAGE format is the sum of the internal storage lengths of the subordinate fields. You determine these internal storage lengths as follows:

- Fields of type I have a value of 4.
- Fields of type F have a value of 4.
- Fields of type P that are 8 bytes can have a USAGE of P15 or P16 (sign and decimal for a total of 15 digits). Fields that are 16 bytes have a USAGE of P17 or larger.
- Fields of type D have a value of 8.
- Alphanumeric fields have a value equal to the number of characters they contain as their field length.

Note:

- Since all group fields must be defined in alphanumeric format, those that include numeric component fields should not be used as verb objects in a report request.
- The MISSING attribute is not supported on the group field, but is supported on the individual fields comprising the group.

Syntax: How to Describe a DB Heritage Files Group Field

```
GROUP = keyname, ALIAS = KEY, USAGE = Ann, ACTUAL = Ann ,$
```

where:

keyname

Can have up to 66 characters.

Example: Describing a DB Heritage Files Group Field

In the library data source, the first field, PUBNO, can be described as a group key. The publisher's number consists of three elements: a number that identifies the publisher, one that identifies the author, and one that identifies the title. They can be described as a group key, consisting of a separate field for each element if the data source is a DB Heritage Files data structure. The Master File looks as follows:

```
FILE = LIBRARY5, SUFFIX = DBFILE,$
 SEGMENT = ROOT, SEGTYPE = S0,$
  GROUP = BOOKKEY      ,ALIAS = KEY ,USAGE = A10    ,ACTUAL = A10  ,$
   FIELDNAME = PUBNO   ,ALIAS = PN  ,USAGE = A3     ,ACTUAL = A3   ,$
   FIELDNAME = AUTHNO  ,ALIAS = AN  ,USAGE = A3     ,ACTUAL = A3   ,$
   FIELDNAME = TITLNO  ,ALIAS = TN  ,USAGE = A4     ,ACTUAL = A4   ,$
   FIELDNAME = AUTHOR   ,ALIAS = AT  ,USAGE = A25   ,ACTUAL = A25  ,$
   FIELDNAME = TITLE    ,ALIAS = TL  ,USAGE = A50   ,ACTUAL = A50  ,$
   FIELDNAME = BINDING  ,ALIAS = BI  ,USAGE = A1    ,ACTUAL = A1   ,$
   FIELDNAME = PRICE    ,ALIAS = PR  ,USAGE = D8.2N ,ACTUAL = D8   ,$
   FIELDNAME = SERIAL   ,ALIAS = SN  ,USAGE = A15   ,ACTUAL = A15  ,$
   FIELDNAME = SYNOPSIS ,ALIAS = SY  ,USAGE = A150  ,ACTUAL = A150 ,$
   FIELDNAME = RECTYPE  ,ALIAS = B   ,USAGE = A1    ,ACTUAL = A1   ,$
```

Example: Describing a DB Heritage Files Group Field With Multiple Formats

```
GROUP = A, ALIAS = KEY, USAGE = A14, ACTUAL = A8   ,$
 FIELDNAME = F1, ALIAS = F1, USAGE = P6, ACTUAL=P2 ,$
 FIELDNAME = F2, ALIAS = F2, USAGE = I9, ACTUAL=I4 ,$
 FIELDNAME = F3, ALIAS = F3, USAGE = A2, ACTUAL=A2 ,$
```

The lengths of the ACTUAL attributes for subordinate fields F1, F2, and F3 total 8, which is the length of the ACTUAL attribute of the group key. The display lengths of the USAGE attributes for the subordinate fields total 17. However, the length of the group key USAGE attribute is found by adding their internal storage lengths as specified by their field types: 8 for USAGE=P6, 4 for USAGE=I9, and 2 for USAGE=A2, for a total of 14.

Example: Accessing a Group Field With Multiple Formats

When you use a group field with multiple formats in a query, you must account for each position in the group, including trailing blanks or leading zeros. The following example illustrates how to access a group field with multiple formats in a query.

```
GROUP = GRPB, ALIAS = KEY, USAGE = A8, ACTUAL = A8 ,$
 FIELDNAME = FIELD1, ALIAS = F1, USAGE = A2, ACTUAL = A2 ,$
 FIELDNAME = FIELD2, ALIAS = F2, USAGE = I8, ACTUAL = I4 ,$
 FIELDNAME = FIELD3, ALIAS = F3, USAGE = A2, ACTUAL = A2 ,$
```

The values in fields F1 and F3 may include some trailing blanks, and the values in field F2 may include some leading zeros. When using the group in a query, you must account for each position. Because FIELD2 is a numeric field, you cannot specify the IF criteria as follows:

```
IF GRPB EQ 'A 0334BB'
```

You can eliminate this error by using a slash (/) to separate the components of the group key.

```
IF GRPB EQ 'A/334/BB'
```

Note: Blanks and leading zeros are assumed where needed to fill out the key.

Describe these multiply occurring fields by placing them in a separate segment. Fields A and B are placed in the root segment. Fields C1 and C2, which occur multiply in relation to A and B, are placed in a descendant segment. You use an additional segment attribute, the OCCURS attribute, to specify that these segments represent multiply occurring fields. In certain cases, you may also need a second attribute, called the POSITION attribute.

Using the OCCURS Attribute

The OCCURS attribute is an optional segment attribute used to describe records containing repeating fields or groups of fields. Define such records by describing the singly occurring fields in one segment, and the multiply occurring fields in a descendant segment. The OCCURS attribute appears in the declaration for the descendant segment.

You can have several sets of repeating fields in your data structure. Describe each of these sets of fields as a separate segment in your data source description. Sets of repeating fields can be divided into two basic types: parallel and nested.

Syntax: **How to Specify a Repeating Field**

```
OCCURS = occurstype
```

Possible values for *occurstype* are:

n

Is an integer value showing the number of occurrences (from 1 to 4095).

fieldname

Names a field in the parent segment whose integer value contains the number of occurrences of the descendant segment.

VARIABLE

Indicates that the number of occurrences varies from record to record. The number of occurrences is computed from the record length (for example, if the field lengths for the segment add up to 40, and 120 characters are read in, it means there are three occurrences).

Place the OCCURS attribute in your segment declaration after the PARENT attribute.

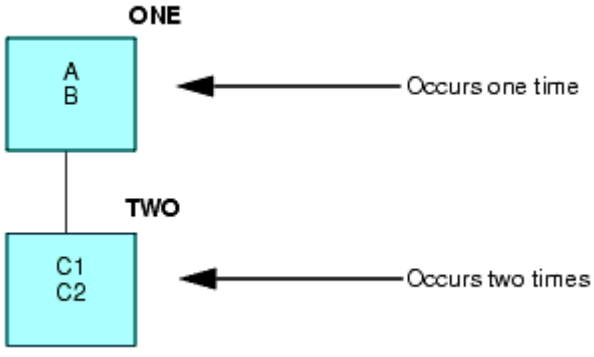
When different types of records are combined in one data source, each record type can contain only one segment defined as OCCURS=VARIABLE. It may have OCCURS descendants (if it contains a nested group), but it may not be followed by any other segment with the same parent—that is, there can be no other segments to its right in the hierarchical data structure. This restriction is necessary to ensure that data in the record is interpreted unambiguously.

Example: **Using the OCCURS Attribute**

Consider the following simple data structure:

A	B	C1	C2	C1	C2

You have two occurrences of fields C1 and C2 for every one occurrence of fields A and B. Thus, to describe this data source, you place fields A and B in the root segment, and fields C1 and C2 in a descendant segment, as shown here.



Describe this data source as follows:

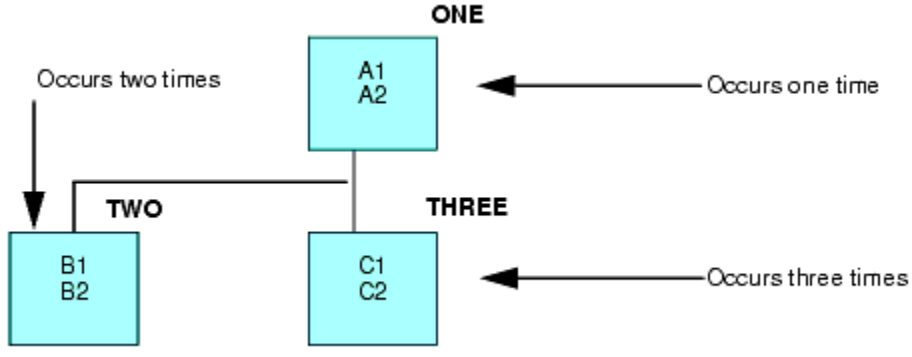
```
FILENAME = EXAMPLE1, SUFFIX = FIX, $
 SEGNAME = ONE, SEGTYPE=S0, $
  FIELDNAME = A,  ALIAS=, USAGE = A2, ACTUAL = A2, $
  FIELDNAME = B,  ALIAS=, USAGE = A1, ACTUAL = A1, $
 SEGNAME = TWO, PARENT = ONE, OCCURS = 2, SEGTYPE=S0, $
  FIELDNAME = C1, ALIAS=, USAGE = I4, ACTUAL = I2, $
  FIELDNAME = C2, ALIAS=, USAGE = I4, ACTUAL = I2, $
```

Describing a Parallel Set of Repeating Fields

Parallel sets of repeating fields are those that have nothing to do with one another (that is, they have no parent-child or logical relationship). Consider the following data structure:

A1	A2	B1	B2	B1	B2	C1	C2	C1	C2	C1	C2

In this example, fields B1 and B2 and fields C1 and C2 repeat within the record. The number of times that fields B1 and B2 occur has nothing to do with the number of times fields C1 and C2 occur. Fields B1 and B2 and fields C1 and C2 are parallel sets of repeating fields. They should be described in the data source description as children of the same parent, the segment that contains fields A1 and A2. The following data structure reflects their relationship.

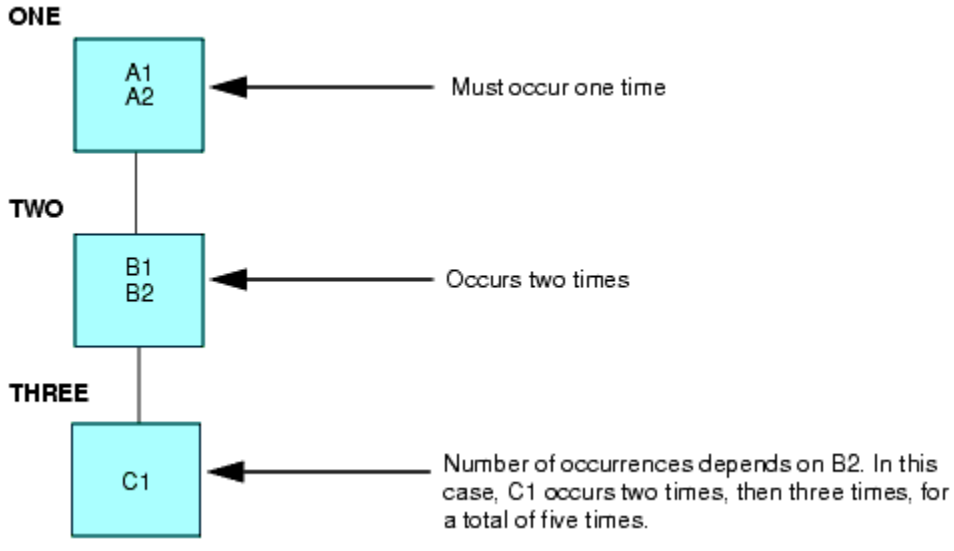


Describing a Nested Set of Repeating Fields

Nested sets of repeating fields are those whose occurrence depends on one another in some way. Consider the following data structure:

A1	A2	B1	B2	C1	C1	B1	B2	C1	C1	C1

In this example, field C1 only occurs after fields B1 and B2 occur once. It occurs varying numbers of times, recorded by a counter field, B2. There is not a set of occurrences of C1 which is not preceded by an occurrence of fields B1 and B2. Fields B1, B2, and C1 are a nested set of repeating fields. They can be represented by the following data structure.



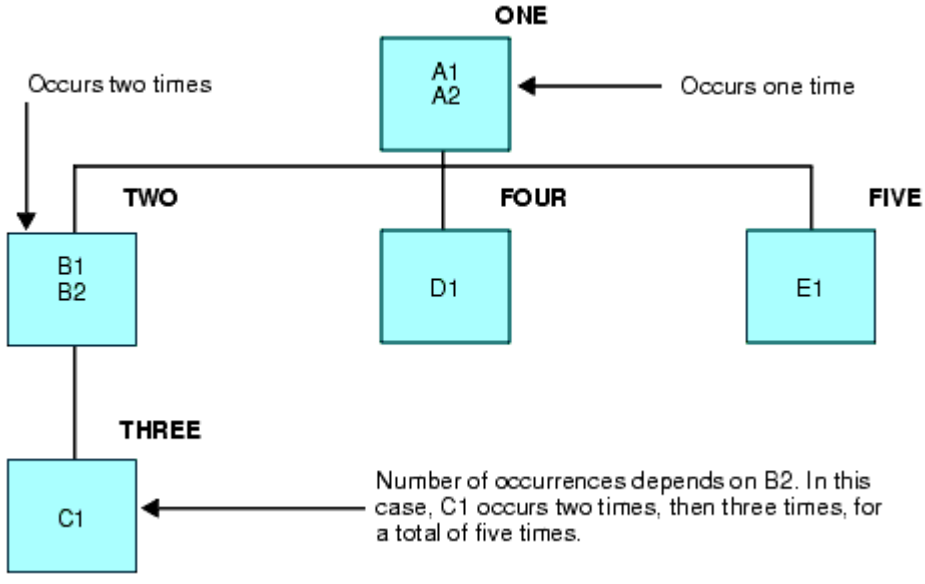
Since field C1 repeats with relation to fields B1 and B2, which repeat in relation to fields A1 and A2, field C1 is described as a separate, descendant segment of Segment TWO, which is in turn a descendant of Segment ONE.

Example: **Describing Parallel and Nested Repeating Fields**

The following data structure contains both nested and parallel sets of repeating fields.

A1	A2	B1	B2	C1	C1	C1	B1	B2	C1	C1	C1	C1	D1	D1	E1	E1	E1	E1

It produces the following data structure.



Describe this data source as follows. Notice that the assignment of the PARENT attributes shows you how the occurrences are nested.

```
FILENAME = EXAMPLE3, SUFFIX = FIX,$
 SEGNAME = ONE,    SEGTYPE=S0,$
  FIELDNAME = A1 ,ALIAS= ,ACTUAL = A1  ,USAGE = A1  ,$
  FIELDNAME = A2 ,ALIAS= ,ACTUAL = I1  ,USAGE = I1  ,$
 SEGNAME = TWO,    SEGTYPE=S0, PARENT = ONE, OCCURS = 2  ,$
  FIELDNAME = B1 ,ALIAS= ,ACTUAL = A15 ,USAGE = A15 ,$
  FIELDNAME = B2 ,ALIAS= ,ACTUAL = I1  ,USAGE = I1  ,$
 SEGNAME = THREE, SEGTYPE=S0, PARENT = TWO, OCCURS = B2 ,$
  FIELDNAME = C1 ,ALIAS= ,ACTUAL = A25 ,USAGE = A25 ,$
 SEGNAME = FOUR,  SEGTYPE=S0, PARENT = ONE, OCCURS = A2 ,$
  FIELDNAME = D1 ,ALIAS= ,ACTUAL = A15 ,USAGE = A15 ,$
 SEGNAME = FIVE,  SEGTYPE=S0, PARENT = ONE, OCCURS = VARIABLE,$
  FIELDNAME = E1 ,ALIAS= ,ACTUAL = A5  ,USAGE = A5  ,$
```

Note:

- Segments ONE, TWO, and THREE represent a nested group of repeating segments. Fields B1 and B2 occur a fixed number of times, so OCCURS equals 2. Field C1 occurs a certain number of times within each occurrence of fields B1 and B2. The number of times C1 occurs is determined by the value of field B2, which is a counter. In this case, its value is 3 for the first occurrence of Segment TWO and 4 for the second occurrence.

- Segments FOUR and FIVE consist of fields that repeat independently within the parent segment. They have no relationship to each other or to Segment TWO except their common parent, so they represent a parallel group of repeating segments.
- As in the case of Segment THREE, the number of times Segment FOUR occurs is determined by a counter in its parent, A2. In this case, the value of A2 is two.
- The number of times Segment FIVE occurs is variable. This means that all the rest of the fields in the record (all those to the right of the first occurrence of E1) are read as recurrences of field E1. To ensure that data in the record is interpreted unambiguously, a segment defined as OCCURS=VARIABLE must be at the end of the record. In a data structure diagram, it is the rightmost segment. Note that there can be only one segment defined as OCCURS=VARIABLE for each record type.

Using the POSITION Attribute

The POSITION attribute is an optional attribute used to describe a structure in which multiply occurring fields with an established number of occurrences are located in the middle of the record. You describe the data source as a hierarchical structure, made up of a parent segment and at least one child segment that contains the multiply occurring fields. The parent segment is made up of whatever singly occurring fields are in the record, as well as one or more alphanumeric fields that appear where the multiply occurring fields appear in the record. The alphanumeric field may be a dummy field that is the exact length of the combined multiply occurring fields. For example, if you have four occurrences of an eight-character field, the length of the field in the parent segment is 32 characters.

You can also use the POSITION attribute to re-describe fields with SEGTYPE=U. See *Redefining a Field in a DB Heritage Files Data Source* on page 572.

Syntax: How to Specify the Position of a Repeating Field

The POSITION attribute is described in the child segment. It gives the name of the field in the parent segment that specifies the starting position and overall length of the multiply occurring fields. The syntax of the POSITION attribute is

```
POSITION = fieldname
```

where:

fieldname

Is the name of the field in the parent segment that defines the starting position of the multiple field occurrences.

Example: **Specifying the Position of a Repeating Field**

Consider the following data structure:

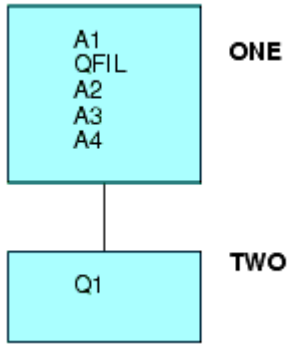
A1	Q1	Q1	Q1	Q1	A2	A3	A4

In this example, field Q1 repeats four times in the middle of the record. When you describe this structure, you specify a field or fields that occupy the position of the four Q1 fields in the record. You then assign the actual Q1 fields to a multiply occurring descendant segment. The POSITION attribute, specified in the descendant segment, gives the name of the field in the parent segment that identifies the starting position and overall length of the Q fields.

Use the following Master File to describe this structure.

```
FILENAME = EXAMPLE3, SUFFIX = FIX,$
 SEGNAME = ONE, SEGTYPE=S0,$
  FIELDNAME = A1    ,ALIAS= ,USAGE = A14 ,ACTUAL = A14 ,$
  FIELDNAME = QFIL  ,ALIAS= ,USAGE = A32 ,ACTUAL = A32 ,$
  FIELDNAME = A2    ,ALIAS= ,USAGE = I2  ,ACTUAL = I2  ,$
  FIELDNAME = A3    ,ALIAS= ,USAGE = A10 ,ACTUAL = A10 ,$
  FIELDNAME = A4    ,ALIAS= ,USAGE = A15 ,ACTUAL = A15 ,$
 SEGNAME = TWO, SEGTYPE=S0, PARENT = ONE, POSITION = QFIL, OCCURS = 4 ,$
  FIELDNAME = Q1    ,ALIAS= ,USAGE = D8  ,ACTUAL = D8  ,$
```

This produces the following structure:



If the total length of the multiply occurring fields is longer than 4095, you can use a filler field after the dummy field to make up the remaining length. This is required, because the format of an alphanumeric field cannot exceed 4095 bytes.

Notice that this structure works only if you have a fixed number of occurrences of the repeating field. This means the OCCURS attribute of the descendant segment must be of the type OCCURS=*n*. OCCURS=*fieldname* or OCCURS=VARIABLE does not work.

Specifying the ORDER Field

In an OCCURS segment, the order of the data may be significant. For example, the values may represent monthly or quarterly data, but the record itself may not explicitly specify the month or quarter to which the data applies.

To associate a sequence number with each occurrence of the field, you may define an internal counter field in any OCCURS segment. A value is automatically supplied that defines the sequence number of each repeating group.

Syntax: How to Specify the Sequence of a Repeating Field

The syntax rules for an ORDER field are:

- It must be the last field described in an OCCURS segment.
- The field name is arbitrary.
- The ALIAS is ORDER.
- The USAGE is I*n*, with any appropriate edit options.
- The ACTUAL is I4.

For example:

```
FIELD = ACT_MONTH, ALIAS = ORDER, USAGE = I2MT, ACTUAL = I4, $
```

Order values are 1, 2, 3, and so on, within each occurrence of the segment. The value is assigned prior to any selection tests that might accept or reject the record, and so it can be used in a selection test.

For example, to obtain data for only the month of June, type:

```
SUM AMOUNT...
WHERE ACT_MONTH IS 6
```

The ORDER field is a virtual field used internally. It does not alter the logical record length (LRECL) of the data source being accessed.

Redefining a Field in a DB Heritage Files Data Source

Redefining record fields in non-FOCUS data sources is supported. This enables you to describe a field with an alternate layout.

Within the Master File, the redefined fields must be described in a separate unique segment (SEGTYPE=U) using the POSITION=*fieldname* and OCCURS=1 attributes.

The redefined fields can have any user-defined name.

Syntax: How to Redefine a Field

```
SEGNAME = segname, SEGTYPE = U, PARENT = parentseg,
OCCURS = 1, POSITION = fieldname,$
```

where:

segname

Is the name of the segment.

parentseg

Is the name of the parent segment.

fieldname

Is the name of the first field being redefined. Using the unique segment with redefined fields helps avoid problems with multipath reporting.

A one-to-one relationship forms between the parent record and the redefined segment.

Example: Redefining a DB Heritage Files Structure

The following example illustrates redefinition of the DB Heritage Files structure described in the COBOL file description, where the COBOL FD is:

```
01 ALLFIELDS
  02 FLD1   PIC X(4)         -  this describes alpha/numeric data
  02 FLD2   PIC X(4)         -  this describes numeric data
  02 RFLD1  PIC 9(5)V99 COMP-3 REDEFINES FLD2
  02 FLD3   PIC X(8)         -  this describes alpha/numeric data

FILE = REDEF, SUFFIX = DBFILE,$
 SEGNAME = ONE, SEGTYPE = S0,$
  GROUP = RKEY, ALIAS = KEY, USAGE = A4 ,ACTUAL = A4 ,$
   FIELDNAME = FLD1,,  USAGE = A4   ,ACTUAL = A4 ,$
   FIELDNAME = FLD2,,  USAGE = A4   ,ACTUAL = A4 ,$
   FIELDNAME = FLD3,,  USAGE = A8   ,ACTUAL = A8 ,$
 SEGNAME = TWO, SEGTYPE = U, POSITION = FLD2, OCCURS = 1, PARENT = ONE ,$
   FIELDNAME = RFLD1,, USAGE = P8.2 ,ACTUAL = Z4 ,$
```

Reference: Special Considerations for Redefining a Field

- Redefinition is a read-only feature and is used only for presenting an alternate view of the data. It is not used for changing the format of the data.

- For non-alphanumeric fields, you must know your data. Attempts to print numeric fields that contain alphanumeric data produce data exceptions or errors converting values. It is recommended that the first definition always be alphanumeric to avoid conversion errors.
- More than one field can be redefined in a segment.
- Redefines are supported only for IDMS, IMS, VSAM, DB Heritage Files, Db2, and FIX data sources.

Extra-Large Record Length Support With DB Heritage Files

If a Master File describes a data source with records longer than 12K, which is typical for OCCURS segments and varchar fields, you must specify a larger record size in advance.

Syntax: How to Define the Maximum Record Length

```
SET MAXLRECL = nnnnn
```

where:

nnnnn

Is up to 32768.

For example, SET MAXLRECL=12000 allows handling of records that are 12000 bytes long. Once you have entered the SET MAXLRECL command, you can obtain the current value of the MAXLRECL parameter by using the ? SET MAXLRECL command.

If the actual record length is longer than specified, retrieval halts and the actual record length appears in hexadecimal notation.

Describing Multiple Record Types in DB Heritage Files

DB Heritage Files data sources can contain more than one type of record. When they do, they can be structured in one of two ways:

- A positional relationship may exist between the various record types, with a record of one type being followed by one or more records containing detailed information about the first record.

  If a positional relationship exists between the various record types, with a parent record of one type followed by one or more child records containing detail information about the parent, you describe the structure by defining the parent as the root, and the detail segments as descendants.

Some DB Heritage Files data sources are structured so that descendant records relate to each other through concatenating key fields. That is, the key fields of a parent record serve as the first part of the key of a child record. In such cases, the segment's key fields must be described using a GROUP declaration. Each segment's GROUP key fields consist of the renamed key fields from the parent segment plus the unique key field from the child record.

- The records have no meaningful positional relationship, and records of varying types exist independently of each other in the data source.

  If the records have no meaningful positional relationship, you have to provide some means for interpreting the type of record that has been read. Do this by creating a dummy root segment for the records.

Key-sequenced DB Heritage Files data sources also use the RECTYPE attribute to distinguish various record types within the data source.

A parent does not always share its RECTYPE with its descendants. It may share some other identifying piece of information, such as the PUBNO in the example. This is the field that should be included in the parent key, as well as all of its descendant keys, to relate them.

When using the RECTYPE attribute in DB Heritage Files data sources with group keys, the RECTYPE field can be part of the segment group key only when it belongs to a segment that has no descendants, or to a segment whose descendants are described with an OCCURS attribute. In *Describing Positionally Related Records* on page 577, the RECTYPE field is added to the group key in the SERIANO segment, the lowest descendant segment in the chain.

Describing a RECTYPE Field

When a data source contains multiple record types, there must be a field in the records themselves that can be used to differentiate between the record types. You can find information on this field in your existing description of the data source (for example, a COBOL FD statement). This field must appear in the same physical location of each record. For example, columns 79 and 80 can contain a different two-digit code for each unique record type. Describe this identifying field with the field name RECTYPE.

Another technique for redefining the parts of records is to use the MAPFIELD and MAPVALUE attributes described in *Describing a Repeating Group Using MAPFIELD* on page 591.

Syntax: How to Specify a Record Type Field

The RECTYPE field must fall in the same physical location of each record in the data source, or the record is ignored. The syntax to describe the RECTYPE field is

```
FIELDNAME = RECTYPE, ALIAS = value, USAGE = format, ACTUAL = format,
ACCEPT = {list|range} ,$
```

where:

value

Is the record type in alphanumeric format, if an ACCEPT list is not specified. If there is an ACCEPT list, this can be any value.

format

Is the data type of the field. In addition to RECTYPE fields in alphanumeric format, RECTYPE fields in packed and integer formats (formats P and I) are supported. Possible values are:

A*n* (where *n* is 1-4095) indicates character data, including letters, digits, and other characters.

I*n* indicates ACTUAL (internal) format binary integers:

- I1 = single-byte binary integer.
- I2 = half-word binary integer (2 bytes).
- I4 = full-word binary integer (4 bytes).

The USAGE format can be I1 through I9, depending on the magnitude of the ACTUAL format.

P*n* (where *n* is 1-16) indicates packed decimal ACTUAL (internal) format. n is the number of bytes, each of which contains two digits, except for the last byte which contains a digit and the sign. For example, P6 means 11 digits plus a sign.

If the field contains an assumed decimal point, represent the field with a USAGE format of P*m.n*, where *m* is the total number of digits, and *n* is the number of decimal places. Thus, P11.1 means an eleven-digit number with one decimal place.

list

Is a list of one or more lines of specific RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Separate each item in the list with either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks. The list may contain a single RECTYPE value. For example:

```
FIELDNAME = RECTYPE, ALIAS = TYPEABC, USAGE = A1,
ACTUAL = A1, ACCEPT = A OR B OR C, $
```

range

Is a range of one or more lines of RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed within single quotation marks.

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order. For example:

```
FIELDNAME = RECTYPE, ALIAS = ACCTREC, USAGE = P3,
ACTUAL = P2, ACCEPT = 100 TO 200, $
```

Example: Specifying the RECTYPE Field

The following field description is of a one-byte packed RECTYPE field containing the value 1:

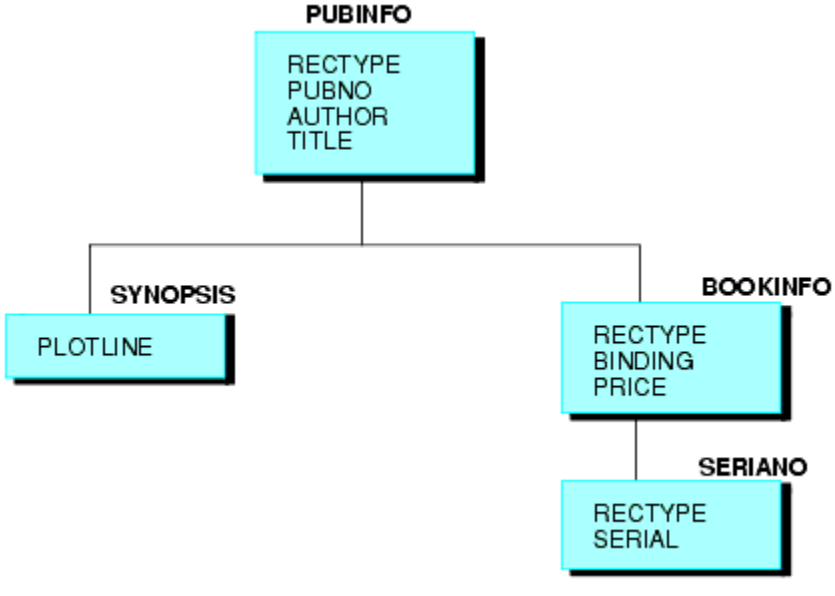
```
FIELD = RECTYPE, ALIAS = 1, USAGE = P1, ACTUAL = P1, $
```

The following field description is of a three-byte alphanumeric RECTYPE field containing the value A34:

```
FIELD = RECTYPE, ALIAS = A34, USAGE = A3, ACTUAL = A3,$
```

Describing Positionally Related Records

The following diagram shows a more complex version of the library data source.



Information that is common to all copies of a given book (the identifying number, the author name, and its title) has the same record type. All of this information is assigned to the root segment in the Master File. The synopsis is common to all copies of a given book, but in this data source it is described as a series of repeating fields of ten characters each, in order to save space.

The synopsis is assigned to its own subordinate segment with an attribute of OCCURS=VARIABLE in the Master File. Although there are segments in the diagram to the right of the OCCURS=VARIABLE segment, OCCURS=VARIABLE is the rightmost segment within its own record type. Only segments with a RECTYPE that is different from the OCCURS=VARIABLE segment can appear to its right in the structure. Note also that the OCCURS=VARIABLE segment does not have a RECTYPE. This is because it is part of the same record as its parent segment.

Binding and price can vary among copies of a given title. For instance, the library may have two different versions of *Pamela*, one a paperback costing $7.95, the other a hardcover costing $15.50. These two fields are of a second record type, and are assigned to a descendant segment in the Master File.

Finally, every copy of the book in the library has its own identifying serial number, which is described in a field of record type S. In the Master File, this information is assigned to a segment that is a child of the segment containing the binding and price information.

Use the following Master File to describe this data source:

```
FILENAME = LIBRARY2, SUFFIX = FIX,$
 SEGNAME = PUBINFO, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = P     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = PUBNO    ,ALIAS = PN    ,USAGE = A10   ,ACTUAL = A10 ,$
  FIELDNAME = AUTHOR   ,ALIAS = AT    ,USAGE = A25   ,ACTUAL = A25 ,$
  FIELDNAME = TITLE    ,ALIAS = TL    ,USAGE = A50   ,ACTUAL = A50 ,$
 SEGNAME = SYNOPSIS, PARENT = PUBINFO,  OCCURS = VARIABLE, SEGTYPE = S0,$
  FIELDNAME = PLOTLINE ,ALIAS = PLOTL ,USAGE = A10   ,ACTUAL = A10 ,$
 SEGNAME = BOOKINFO, PARENT = PUBINFO,  SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = B     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = BINDING  ,ALIAS = BI    ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = PRICE    ,ALIAS = PR    ,USAGE = D8.2N ,ACTUAL = D8  ,$
 SEGNAME = SERIANO,  PARENT = BOOKINFO, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = S     ,USAGE = A1    ,ACTUAL = A1  ,$
  FIELDNAME = SERIAL   ,ALIAS = SN    ,USAGE = A15   ,ACTUAL = A15 ,$
```

Note that each segment, except OCCURS, contains a field named RECTYPE and that the ALIAS for the field contains a unique value for each segment (P, B, and S). If there is a record in this data source with a RECTYPE other than P, B, or S, the record is ignored. The RECTYPE field must fall in the same physical location in each record.

Ordering of Records in the Data Source

Physical order determines parent/child relationships in sequential records. Every parent record does not need descendants. Specify how you want data in missing segment instances handled in your reports by using the SET command to change the ALL parameter.

In the example *Describing Positionally Related Records* on page 577, if the first record in the data source is not a PUBINFO record, the record is considered to be a child without a parent. Any information allotted to the SYNOPSIS segment appears in the PUBINFO record. The next record may be a BOOKINFO or even another PUBINFO (in which case the first PUBINFO is assumed to have no descendants). Any SERIANO records are assumed to be descendants of the previous BOOKINFO record. If a SERIANO record follows a PUBINFO record with no intervening BOOKINFO, it is treated as if it has no parent.

Example: Describing DB Heritage Files Positionally Related Records

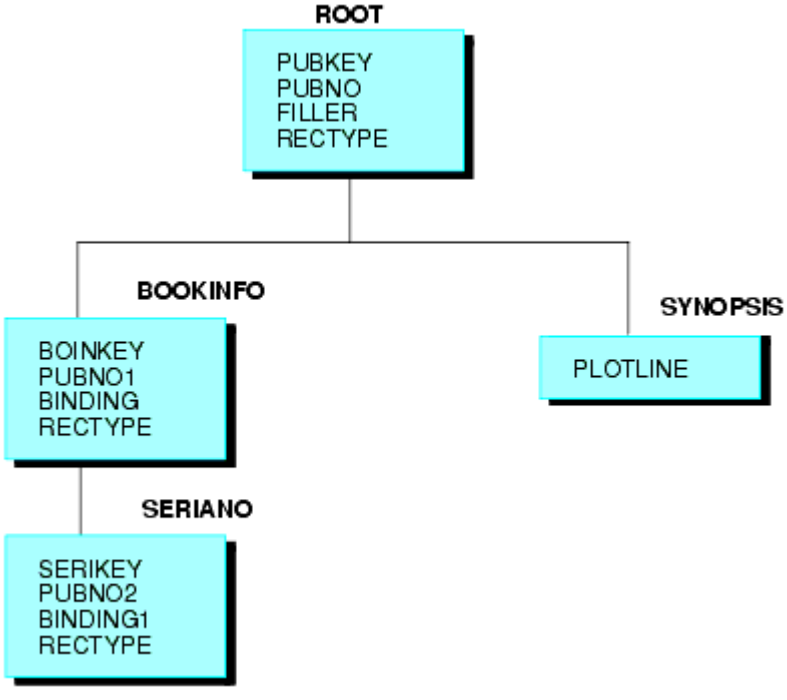
Consider the following DB Heritage Files data source that contains three types of records. The ROOT records have a key that consists of the publisher number, PUBNO. The BOOKINFO segment has a key that consists of that same publisher number, plus a hard- or soft-cover indicator, BINDING. The SERIANO segment key consists of the first two elements, plus a record type field, RECTYPE.

```
FILENAME = LIBRARY6, SUFFIX = DBFILE,$
 SEGNAME = ROOT, SEGTYPE = S0,$
  GROUP=PUBKEY         ,ALIAS=KEY   ,USAGE=A10   ,ACTUAL=A10  ,$
   FIELDNAME=PUBNO     ,ALIAS=PN    ,USAGE=A10   ,ACTUAL=A10  ,$
  FIELDNAME=FILLER     ,ALIAS=      ,USAGE=A1    ,ACTUAL=A1   ,$
  FIELDNAME=RECTYPE    ,ALIAS=1     ,USAGE=A1    ,ACTUAL=A1   ,$
  FIELDNAME=AUTHOR     ,ALIAS=AT    ,USAGE=A25   ,ACTUAL=A25  ,$
  FIELDNAME=TITLE      ,ALIAS=TL    ,USAGE=A50   ,ACTUAL=A50  ,$
 SEGNAME=BOOKINFO,PARENT=ROOT,   SEGTYPE=S0,$
  GROUP=BOINKEY        ,ALIAS=KEY   ,USAGE=A11   ,ACTUAL=A11  ,$
   FIELDNAME=PUBNO1    ,ALIAS=P1    ,USAGE=A10   ,ACTUAL=A10  ,$
   FIELDNAME=BINDING   ,ALIAS=BI    ,USAGE=A1    ,ACTUAL=A1   ,$
  FIELDNAME=RECTYPE    ,ALIAS=2     ,USAGE=A1    ,ACTUAL=A1   ,$
  FIELDNAME=PRICE      ,ALIAS=PR    ,USAGE=D8.2N ,ACTUAL=D8   ,$
 SEGNAME=SERIANO, PARENT=BOOKINFO,SEGTYPE=S0,$
  GROUP=SERIKEY        ,ALIAS=KEY   ,USAGE=A12   ,ACTUAL=A12  ,$
   FIELDNAME=PUBNO2    ,ALIAS=P2    ,USAGE=A10   ,ACTUAL=A10  ,$
   FIELDNAME=BINDING1  ,ALIAS=B1    ,USAGE=A1    ,ACTUAL=A1   ,$
   FIELDNAME=RECTYPE   ,ALIAS=3     ,USAGE=A1    ,ACTUAL=A1   ,$
  FIELDNAME=SERIAL     ,ALIAS=SN    ,USAGE=A15   ,ACTUAL=A15  ,$
 SEGNAME=SYNOPSIS,PARENT=ROOT,    SEGTYPE=S0, OCCURS=VARIABLE,$
  FIELDNAME=PLOTLINE   ,ALIAS=PLOTL ,USAGE=A10   ,ACTUAL=A10  ,$
```

Notice that the length of the key fields specified in the USAGE and ACTUAL attributes of a GROUP declaration is the length of the key fields from the parent segments, plus the length of the added field of the child segment (RECTYPE field). In the example above, the length of the GROUP key SERIKEY equals the length of PUBNO2 and BINDING1, the group key from the parent segment, plus the length of RECTYPE, the field added to the group key in the child segment. The length of the key increases as you traverse the structure.

Note: Each segment key describes as much of the true key as needed to find the next instance of that segment.

In the sample data source, the repetition of the publisher's number as PUBNO1 and PUBNO2 in the descendant segments interrelates the three types of records. The data source can be diagrammed as the following structure:



A typical query may request information on price and call numbers for a specific publisher number:

```
PRINT PRICE AND SERIAL BY PUBNO
IF PUBNO EQ 1234567890 OR 9876054321
```

Since PUBNO is part of the key, retrieval can occur quickly, and the processing continues. To further speed retrieval, add search criteria based on the BINDING field, which is also part of the key.

Describing Unrelated Records

Some data sources do not have records that are related to one another. That is, the key of one record type is independent of the keys of other record types. To describe data sources with unrelated records, define a dummy root segment for the record types. The following rules apply to the dummy root segment:

- The name of the root segment must be DUMMY.
- It must have only one field with a blank name and alias.
- The USAGE and ACTUAL attributes must both be A1.

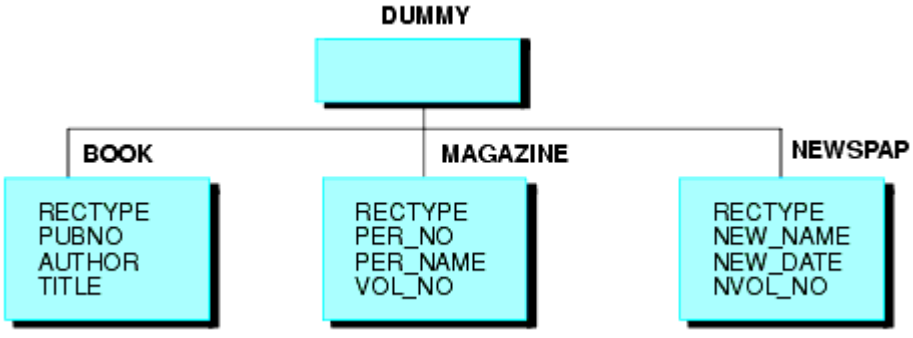
All other non-repeating segments must point to the dummy root as their parent. Except for the root, all non-repeating segments must have a RECTYPE and a PARENT attribute and describe the full key. If the data source does not have a key, the group should not be described. RECTYPEs may be anywhere in the record.

Example: Describing Unrelated Records Using a Dummy Root Segment

The library data source has three types of records: book information, magazine information, and newspaper information. Since these three record types have nothing in common, they cannot be described as parent records followed by detail records.

The data source can look like this:

A structure such as the following can also describe this data source.



The Master File for the structure in this example is:

```
FILENAME = LIBRARY3, SUFFIX = FIX,$
 SEGMENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME=           ,ALIAS=     ,USAGE = A1    ,ACTUAL = A1   ,$
 SEGMENT = BOOK, PARENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = B  ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PUBNO    ,ALIAS = PN ,USAGE = A10   ,ACTUAL = A10  ,$
  FIELDNAME = AUTHOR   ,ALIAS = AT ,USAGE = A25   ,ACTUAL = A25  ,$
  FIELDNAME = TITLE    ,ALIAS = TL ,USAGE = A50   ,ACTUAL = A50  ,$
  FIELDNAME = BINDING  ,ALIAS = BI ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PRICE    ,ALIAS = PR ,USAGE = D8.2N ,ACTUAL = D8   ,$
  FIELDNAME = SERIAL   ,ALIAS = SN ,USAGE = A15   ,ACTUAL = A15  ,$
  FIELDNAME = SYNOPSIS ,ALIAS = SY ,USAGE = A150  ,ACTUAL = A150 ,$
 SEGMENT = MAGAZINE, PARENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = M  ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = PER_NO   ,ALIAS = PN ,USAGE = A10   ,ACTUAL = A10  ,$
  FIELDNAME = PER_NAME ,ALIAS = NA ,USAGE = A50   ,ACTUAL = A50  ,$
  FIELDNAME = VOL_NO   ,ALIAS = VN ,USAGE = I2    ,ACTUAL = I2   ,$
  FIELDNAME = ISSUE_NO ,ALIAS = IN ,USAGE = I2    ,ACTUAL = I2   ,$
  FIELDNAME = PER_DATE ,ALIAS = DT ,USAGE = I6MDY ,ACTUAL = I6   ,$
 SEGMENT = NEWSPAP, PARENT = DUMMY, SEGTYPE = S0,$
  FIELDNAME = RECTYPE  ,ALIAS = N  ,USAGE = A1    ,ACTUAL = A1   ,$
  FIELDNAME = NEW_NAME ,ALIAS = NN ,USAGE = A50   ,ACTUAL = A50  ,$
  FIELDNAME = NEW_DATE ,ALIAS = ND ,USAGE = I6MDY ,ACTUAL = I6   ,$
  FIELDNAME = NVOL_NO  ,ALIAS = NV ,USAGE = I2    ,ACTUAL = I2   ,$
  FIELDNAME = ISSUE    ,ALIAS = NI ,USAGE = I2    ,ACTUAL = I2   ,$
```

Example: Describing a DB Heritage Files Data Source With Unrelated Records

Consider another data source containing information on the library. This data source has three types of records: book information, magazine information, and newspaper information.

There are two possible structures:

The RECTYPE is the beginning of the key. The key structure is:

RECTYPE B	Book Code
RECTYPE M	Magazine Code
RECTYPE N	Newspaper Code

The sequence of records is:

Book
Book
Magazine
Magazine
Newspaper
Newspaper

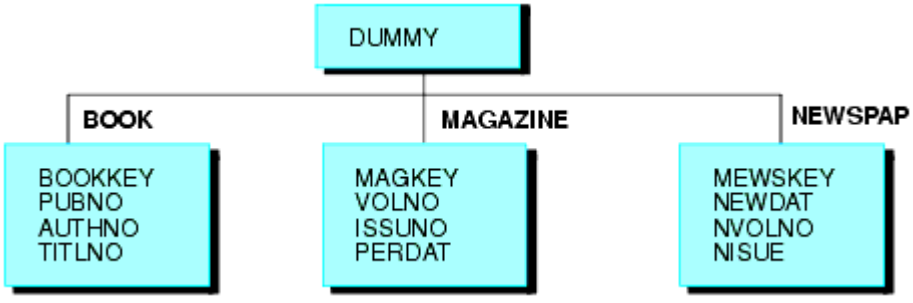
Note the difference between the use of the RECTYPE here and its use when the records are positionally related. In this case, the codes are unrelated and the database designer has chosen to accumulate the records by type first (all the book information together, all the magazine information together, and all the newspaper information together), so the RECTYPE may be the initial part of the key.

The RECTYPE is not in the beginning of the key or is outside of the key. The key structure is:

Book Code
Magazine Code
Newspaper Code

The sequence of record types in the data source can be arbitrary.

Both types of file structure can be represented by the following:



Example: **Describing a Key and a Record Type for a DB Heritage Files Data Source With Unrelated Records**

```
FILE=LIBRARY7, SUFFIX=DBFILE,$
 SEGMENT=DUMMY,$
  FIELDNAME=          ,ALIAS=    ,USAGE=A1     ,ACTUAL=A1   ,$
 SEGMENT=BOOK,      PARENT=DUMMY,SEGTYPE=S0,$
  GROUP=BOOKKEY       ,ALIAS=KEY ,USAGE=A11    ,ACTUAL=A11  ,$
   FIELDNAME=PUBNO    ,ALIAS=PN  ,USAGE=A3     ,ACTUAL=A3   ,$
   FIELDNAME=AUTHNO   ,ALIAS=AN  ,USAGE=A3     ,ACTUAL=A3   ,$
   FIELDNAME=TITLNO   ,ALIAS=TN  ,USAGE=A4     ,ACTUAL=A4   ,$
   FIELDNAME=RECTYPE  ,ALIAS=B   ,USAGE=A1     ,ACTUAL=A1   ,$
  FIELDNAME=AUTHOR    ,ALIAS=AT  ,USAGE=A25    ,ACTUAL=A25  ,$
  FIELDNAME=TITLE     ,ALIAS=TL  ,USAGE=A50    ,ACTUAL=A50  ,$
  FIELDNAME=BINDING   ,ALIAS=BI  ,USAGE=A1     ,ACTUAL=A1   ,$
  FIELDNAME=PRICE     ,ALIAS=PR  ,USAGE=D8.2N  ,ACTUAL=D8   ,$
  FIELDNAME=SERIAL    ,ALIAS=SN  ,USAGE=A15    ,ACTUAL=A15  ,$
  FIELDNAME=SYNOPSIS  ,ALIAS=SY  ,USAGE=A150   ,ACTUAL=A150 ,$
 SEGMENT=MAGAZINE,  PARENT=DUMMY,  SEGTYPE=S0,$
  GROUP=MAGKEY        ,ALIAS=KEY ,USAGE=A11    ,ACTUAL=A11  ,$
   FIELDNAME=VOLNO    ,ALIAS=VN  ,USAGE=A2     ,ACTUAL=A2   ,$
   FIELDNAME=ISSUNO   ,ALIAS=IN  ,USAGE=A2     ,ACTUAL=A2   ,$
   FIELDNAME=PERDAT   ,ALIAS=DT  ,USAGE=A6     ,ACTUAL=A6   ,$
   FIELDNAME=RECTYPE  ,ALIAS=M   ,USAGE=A1     ,ACTUAL=A1   ,$
  FIELDNAME=PER_NAME  ,ALIAS=PRN ,USAGE=A50    ,ACTUAL=A50  ,$
 SEGMENT=NEWSPAP,   PARENT=DUMMY,  SEGTYPE=S0,$
  GROUP=NEWSKEY       ,ALIAS=KEY ,USAGE=A11    ,ACTUAL=A11  ,$
   FIELDNAME=NEWDAT   ,ALIAS=ND  ,USAGE=A6     ,ACTUAL=A6   ,$
   FIELDNAME=NVOLNO   ,ALIAS=NV  ,USAGE=A2     ,ACTUAL=A2   ,$
   FIELDNAME=NISSUE   ,ALIAS=NI  ,USAGE=A2     ,ACTUAL=A2   ,$
   FIELDNAME=RECTYPE  ,ALIAS=N   ,USAGE=A1     ,ACTUAL=A1   ,$
  FIELDNAME=NEWNAME   ,ALIAS=NN  ,USAGE=A50    ,ACTUAL=A50  ,$
```

Using a Generalized Record Type

If your data source has multiple record types that share the same layout, you can specify a single generalized segment that describes all record types that have the common layout. By using a generalized segment, also known as a generalized RECTYPE, instead of one segment per record type, you reduce the number of segments you need to describe in the Master File.

When using a generalized segment, you identify RECTYPE values using the ACCEPT attribute. You can assign any value to the ALIAS attribute.

Syntax: How to Specify a Generalized Record Type

```
FIELDNAME = RECTYPE, ALIAS = alias, USAGE = format, ACTUAL = format,
ACCEPT = {list|range} ,$
```

where:

`RECTYPE`

Is the required field name.

Note: Since the field name, RECTYPE, may not be unique across segments, you should not use it in this way unless you qualify it. An alias is not required; you may leave it blank.

`alias`

Is any valid alias specification. You can specify a unique name as the alias value for the RECTYPE field only if you use the ACCEPT attribute. The alias can then be used in a TABLE request as a display field, a sort field, or in selection tests using either WHERE or IF.

`list`

Is a list of one or more lines of specific RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks. The list may contain a single RECTYPE value. For example:

```
FIELDNAME = RECTYPE, ALIAS = TYPEABC, USAGE = A1,
ACTUAL = A1, ACCEPT = A OR B OR C, $
```

`range`

Is a range of one or more lines of RECTYPE values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed within single quotation marks.

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order. For example:

```
FIELDNAME = RECTYPE, ALIAS = ACCTREC, USAGE = P3,
ACTUAL = P2, ACCEPT = 100 TO 200, $
```

Example: Using a Generalized Record Type

To illustrate the use of the generalized record type in a Master File, consider the following record layouts in the DOC data source. Record type DN is the root segment and contains the document number and title. Record types M, I, and C contain information about manuals, installation guides, and course guides, respectively. Notice that record types M and I have the same layout.

Record type DN:

```
---KEY---
+-------------------------------------------------------------------------+
DOCID   FILLER         RECTYPE     TITLE
+-------------------------------------------------------------------------+
```

Record type M:

```
--------KEY--------
+-------------------------------------------------------------------------+
MDOCID   MDATE         RECTYPE     MRELEASE          MPAGES     FILLER
+-------------------------------------------------------------------------+
```

Record type I:

```
--------KEY--------
+-------------------------------------------------------------------------+
IDOCID   IDATE         RECTYPE     IRELEASE          IPAGES     FILLER
+-------------------------------------------------------------------------+
```

Record type C:

```
--------KEY--------
+-------------------------------------------------------------------------+
CRSEDOC   CDATE        RECTYPE     COURSENUM  LEVEL  CPAGES     FILLER
+-------------------------------------------------------------------------+
```

Without the ACCEPT attribute, each of the four record types must be described as separate segments in the Master File. A unique set of field names must be provided for record type M and record type I, although they have the same layout.

The generalized RECTYPE capability enables you to code just one set of field names that applies to the record layout for both record type M and I. The ACCEPT attribute can be used for any RECTYPE specification, even when there is only one acceptable value.

```
FILENAME=DOC2, SUFFIX=DBFILE,$
SEGNAME=ROOT, SEGTYPE=SO,$
 GROUP=DOCNUM,     ALIAS=KEY,        A5,  A5,  $
  FIELD=DOCID,     ALIAS=SEQNUM,     A5,  A5,  $
 FIELD=FILLER,     ALIAS,=           A5,  A5,  $
 FIELD=RECTYPE,    ALIAS=DOCRECORD, A3,  A3,  ACCEPT = DN,$
 FIELD=TITLE,      ALIAS=,           A18, A18, $
SEGNAME=MANUALS, PARENT=ROOT, SEGTYPE=SO,$
 GROUP=MDOCNUM,    ALIAS=KEY, A10, A10,$
  FIELD=MDOCID,    ALIAS=MSEQNUM,    A5,  A5,  $
  FIELD=MDATE,     ALIAS=MPUBDATE,   A5,  A5,  $
 FIELD=RECTYPE,    ALIAS=MANUAL,     A3,  A3,  ACCEPT = M OR I,$
 FIELD=MRELEASE,   ALIAS=,           A7,  A7,  $
 FIELD=MPAGES,     ALIAS=,           I5,  A5,  $
 FIELD=FILLER,     ALIAS=,           A6,  A6,  $
SEGNAME=COURSES, PARENT=ROOT, SEGTYPE=SO,$
 GROUP=CRSEDOC,    ALIAS=KEY, A10, A10,$
  FIELD=CDOCID,    ALIAS=CSEQNUM,    A5,  A5,  $
  FIELD=CDATE,     ALIAS=CPUBDATE,   A5,  A5,  $
 FIELD=RECTYPE,    ALIAS=COURSE,     A3,  A3,  ACCEPT = C,$
 FIELD=COURSENUM, ALIAS=CNUM,       A4,  A4,  $
 FIELD=LEVEL,      ALIAS=,           A2,  A2,  $
 FIELD=CPAGES,     ALIAS=,           I5,  A5,  $
 FIELD=FILLER,     ALIAS=,           A7,  A7,  $
```

Combining Multiply-Occurring Fields and Multiple Record Types in DB Heritage Files

You can have two types of descendant segments in a single fixed-format DB Heritage Files data source:

- Descendant segments consisting of multiply occurring fields.
- Additional descendant segments consisting of multiple record types.

Describing a Multiply Occurring Field and Multiple Record Types

In the data structure shown below, the first record, of type 01, contains several different sequences of repeating fields, all of which must be described as descendant segments with an OCCURS attribute. The data source also contains two separate records, of types 02 and 03, which contain information that is related to that in record type 01.

The relationship between the records of various types is expressed as parent-child relationships. The children that contain record types 02 and 03 do not have an OCCURS attribute. They are distinguished from their parent by the field declaration where field=RECTYPE.

01	T1	N1	B1	B2	C1	C1	C1	D1	D1	D1	D1	D1	D1	D1	B1	B2	C1	C1	D1	D1	D1	D1	D1	D1

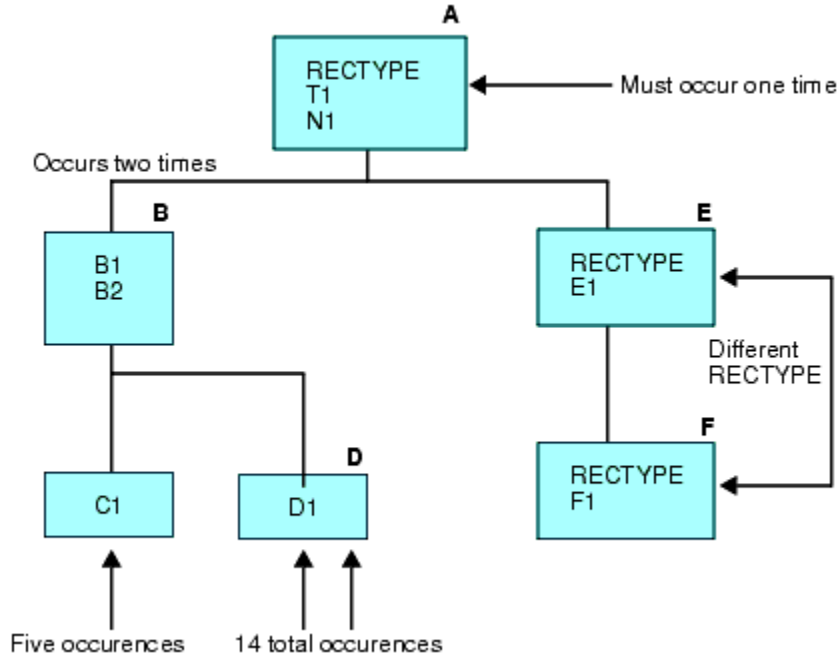
02	E1

03	F1

The description for this data source is:

```
FILENAME = EXAMPLE1, SUFFIX = FIX,$
 SEGNAME = A, SEGTYPE=S0,$
  FIELDNAME = RECTYPE   ,ALIAS = 01   ,USAGE = A2   ,ACTUAL = A2 ,$
  FIELDNAME = T1        ,ALIAS =      ,USAGE = A2   ,ACTUAL = A1 ,$
  FIELDNAME = N1        ,ALIAS =      ,USAGE = A1   ,ACTUAL = A1 ,$
 SEGNAME = B, PARENT = A, OCCURS = VARIABLE, SEGTYPE=S0,$
  FIELDNAME = B1        ,ALIAS =      ,USAGE = I2   ,ACTUAL = I2 ,$
  FIELDNAME = B2        ,ALIAS =      ,USAGE = I2   ,ACTUAL = I2 ,$
 SEGNAME = C, PARENT = B, OCCURS = B1, SEGTYPE=S0,$
  FIELDNAME = C1        ,ALIAS =      ,USAGE = A1   ,ACTUAL = A1 ,$
 SEGNAME = D, PARENT = B, OCCURS = 7,  SEGTYPE=S0,$
  FIELDNAME = D1        ,ALIAS =      ,USAGE = A1   ,ACTUAL = A1 ,$
 SEGNAME = E, PARENT = A, SEGTYPE=S0,$
  FIELDNAME = RECTYPE   ,ALIAS = 02   ,USAGE = A2   ,ACTUAL = A2 ,$
  FIELDNAME = E1        ,ALIAS =      ,USAGE = A1   ,ACTUAL = A1 ,$
 SEGNAME = F, PARENT = E, SEGTYPE=S0,$
  FIELDNAME = RECTYPE   ,ALIAS = 03   ,USAGE = A2   ,ACTUAL = A2 ,$
  FIELDNAME = F1        ,ALIAS =      ,USAGE = A1   ,ACTUAL = A1 ,$
```

It produces the following data structure:



Segments A, B, C, and D all belong to the same record type. Segments E and F each are stored as separate record types.

Note:

- Segments A, E, and F are different records that are related through their record types. The record type attribute consists of certain prescribed values, and is stored in a fixed location in the records. Records are expected to be retrieved in a given order. If the first record does not have a RECTYPE of 01, the record is considered to be a child without a parent. The next record can have a RECTYPE of either 01 (in which case, the first record is considered to have no descendants except the OCCURS descendants) or 02. A record with a RECTYPE of 03 can follow only a record with a RECTYPE of 02 (its parent) or another 03.
- The OCCURS descendants all belong to the record whose RECTYPE is 01. (This is not a necessary condition; records of any type can have OCCURS descendants.) Note that the OCCURS=VARIABLE segment, Segment B, is the rightmost segment within its own record type. If you look at the data structure, the pattern that makes up Segment B and its descendants (the repetition of fields B1, B2, C1, and D1) extends from the first mention of fields B1 and B2 to the end of the record.

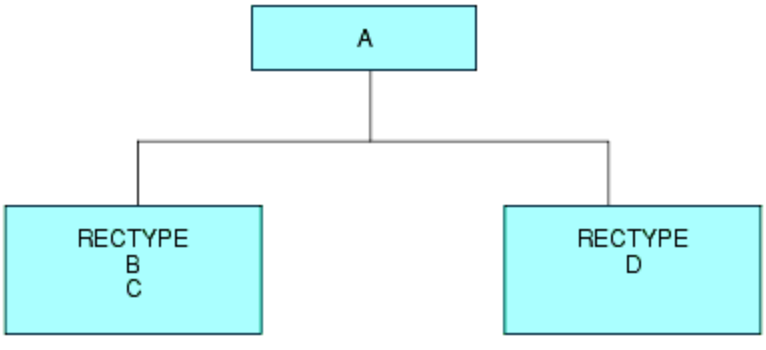
- Although fields C1 and D1 appear in separate segments, they are actually part of the repeating pattern that makes up the OCCURS=VARIABLE segment. Since they occur multiple times within Segment B, they are each assigned to their own descendant segment. The number of times field C1 occurs depends on the value of field B2. In the example, the first value of field B2 is 3; the second, 2. Field D1 occurs a fixed number of times, 7.

Describing a Repeating Group With RECTYPEs

Suppose you want to describe a data source that, schematically, looks like this:

```
A     RECTYPE  B C    RECTYPE   B C
A     RECTYPE  D      RECTYPE   D
```

You need to describe three segments in your Master File, with A as the root segment, and segments for B, C, and D as two descendant OCCURS segments for A.



Each of the two descendant OCCURS segments in this example depends on the RECTYPE indicator that appears for each occurrence.

All the rules of syntax for using RECTYPE fields and OCCURS segments also apply to RECTYPEs within OCCURS segments.

Since each OCCURS segment depends on the RECTYPE indicator for its evaluation, the RECTYPE must appear at the start of the OCCURS segment. This enables you to describe complex data sources, including those with nested and parallel repeating groups that depend on RECTYPEs.

Example: Describing a Repeating Group With RECTYPEs

In this example, B/C, and D represent a nested repeating group, and E represents a parallel repeating group.

A	RECTYPE B C	RECTYPE D	RECTYPE E	RECTYPE E

```
FILENAME=SAMPLE,SUFFIX=DBFILE,$
 SEGNAME=ROOT,SEGTYPE=S0,$
  GROUP=GRPKEY      ,ALIAS=KEY ,USAGE=A8 ,ACTUAL=A8 ,$
   FIELD=FLD000     ,E00       ,A08      ,A08       ,$
   FIELD=A_DATA     ,E01       ,A02      ,A02       ,$
 SEGNAME=SEG001,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0  ,$
  FIELD=RECTYPE     ,A01       ,A01      ,ACCEPT=B OR C ,$
  FIELD=B_OR_C_DATA ,E02       ,A08      ,A08       ,$
 SEGNAME=SEG002,PARENT=SEG001,OCCURS=VARIABLE,SEGTYPE=S0,$
  FIELD=RECTYPE     ,D         ,A01      ,A01       ,$
  FIELD=D_DATA      ,E03       ,A07      ,A07       ,$
 SEGNAME=SEG003,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0  ,$
  FIELD=RECTYPE     ,E         ,A01      ,A01       ,$
  FIELD=E_DATA      ,E04       ,A06      ,A06       ,$
```

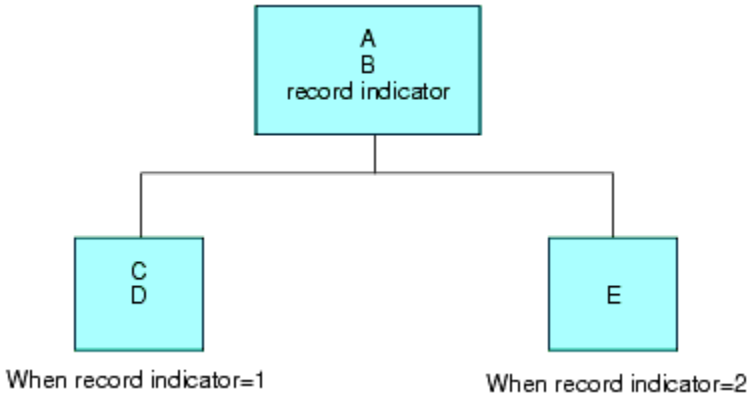
Describing a Repeating Group Using MAPFIELD

In another combination of record indicator and OCCURS, a record contains a record indicator that is followed by a repeating group. In this case, the record indicator is in the fixed portion of the record, not in each occurrence. Schematically, the record appears like this:

A B	record indicator (1)	C D	C D	C D
A B	record indicator (2)	E E		

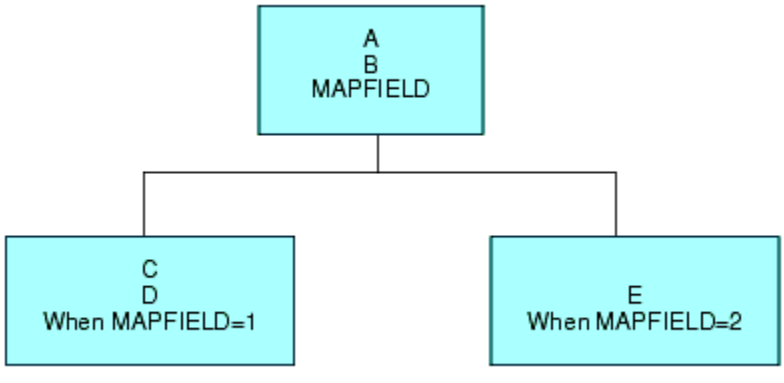
The first record contains header information, values for A and B, followed by an OCCURS segment of C and D that was identified by its preceding record indicator. The second record has a different record indicator and contains a different repeating group, this time for E.

The following diagram illustrates this relationship.



Since the OCCURS segments are identified by the record indicator rather than the parent A/B segment, you must use the keyword MAPFIELD. MAPFIELD identifies a field in the same way as RECTYPE, but since each OCCURS segments has its own value for MAPFIELD, the value of MAPFIELD is associated with each OCCURS segment by means of a complementary field named MAPVALUE.

The following diagram illustrates this relationship.



MAPFIELD is assigned as the ALIAS of the field that is the record indicator. It may have any name.

Syntax: How to Describe a Repeating Group With MAPFIELD

```
FIELD = name, ALIAS = MAPFIELD, USAGE = format, ACTUAL = format,$
```

where:

name

Is the name you choose to provide for this field.

ALIAS

MAPFIELD is assigned as the alias of the field that is the RECTYPE indicator.

USAGE

Follows the usual field format.

ACTUAL

Follows the usual field format.

The descendant segment values depend on the value of the MAPFIELD. They are described as separate segments, one for each possible value of MAPFIELD, and all descending from the segment that has the MAPFIELD. A special field, MAPVALUE, is described as the last field in these descendant segments after the ORDER field, if one has been used. The actual MAPFIELD value is supplied as the ALIAS of MAPVALUE.

Syntax: How to Use MAPFIELD for a Descendant Repeating Segment in a Repeating Group

```
FIELD = MAPVALUE, ALIAS = alias, USAGE = format, ACTUAL = format,
ACCEPT = {list|range} ,$
```

where:

MAPVALUE

Indicates that the segment depends on a MAPFIELD in its parent segment.

alias

Is the primary MAPFIELD value, if an ACCEPT list is not specified. If there is an ACCEPT list, this can be any value.

USAGE

Is the same format as the MAPFIELD format in the parent segment.

ACTUAL

Is the same format as the MAPFIELD format in the parent segment.

list

Is the list of one or more lines of specified MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the list is 255. Each item in the list must be separated by either a blank or the keyword OR. If the list contains embedded blanks or commas, it must be enclosed within single quotation marks ('). The list may contain a single MAPFIELD value.

For example:

```
FIELDNAME = MAPFIELD, ALIAS = A, USAGE = A1, ACTUAL = A1,
ACCEPT = A OR B OR C,$
```

range

Is a range of one or more lines of MAPFIELD values for records that have the same segment layout. The maximum number of characters allowed in the range is 255. If the range contains embedded blanks or commas, it must be enclosed in single quotation marks (').

To specify a range of values, include the lowest value, the keyword TO, and the highest value, in that order.

Example: Using MAPFIELD and MAPVALUE

Using the sample data source at the beginning of this section, the Master File for this data source looks like this:

```
FILENAME=EXAMPLE,SUFFIX=FIX,$
 SEGNAME=ROOT,SEGTYPE=S0,$
  FIELD =A,               ,A14   ,A14 ,$
  FIELD =B,               ,A10   ,A10 ,$
  FIELD =FLAG ,MAPFIELD   ,A01   ,A01 ,$
 SEGNAME=SEG001,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0  ,$
  FIELD =C,               ,A05   ,A05 ,$
  FIELD =D,               ,A07   ,A07 ,$
  FIELD =MAPVALUE ,1      ,A01   ,A01 ,$
 SEGNAME=SEG002,PARENT=ROOT,OCCURS=VARIABLE,SEGTYPE=S0  ,$
  FIELD =E,               ,D12.2 ,D8  ,$
  FIELD =MAPVALUE ,2      ,A01   ,A01 ,$
```

Note: MAPFIELD can only exist on an OCCURS segment that has not been remapped. This means that the segment definition cannot contain POSITION=*fieldname*.

MAPFIELD and MAPVALUE may be used with SUFFIX=FIX and SUFFIX=DBFILE data sources.

Multi-Format Logical Files

Multi-format logical files are an accumulation of different record formats, each one from a separate physical file. Multi-format logical files enable placement of multiple physical files in one logical (hierarchical) file structure. Each of the physical files should have common keys.

Example: Associating a Logical File With Three Physical Files

The following are IBM i Data Description Specifications (DDSs) for three physical files and the logical file that associates them:

```
EMPLOYEE Physical File DDS

0001.00      A                                      UNIQUE
0002.00      A          R EMPINFOR
0003.00      A            EMP_ID         9A
0004.00      A            LAST_NAME     10A
0005.00      A            FIRST_NAME    10A
0006.00      A            ADDRESS       40A
0007.00      A          K EMP_ID

PENSION Physical File DDS

0001.00      A                                      UNIQUE
0002.00      A          R PENSPATH
0003.00      A            EMP_ID         9A
0004.00      A            PLAN_NAME     10A
0005.00      A            VESTED         1A
0006.00      A            AMT_CNTRB      6P 2
0007.00      A          K EMP_ID

VACATION Physical File DDS

0001.00      A                                      UNIQUE
0002.00      A          R VACPATH
0003.00      A            EMP_ID         9A
0004.00      A            DAYS_EARND     2P 1
0005.00      A            DAYS_TAKEN     2P 1
0006.00      A          K EMP_ID

EMP Multi-Format Logical DDS

0001.00      A          R EMPINFOR                   PFILE(EMPLOYEE)
0002.00      A          K EMP_ID
0003.00      A          R PENSPATH                   PFILE(PENSION)
0004.00      A          K EMP_ID
0005.00      A          R VACPATH                    PFILE(VACATION)
0006.00      A          K EMP_ID
```

When you create a synonym for the EMP Multi-format logical file, the following metadata is generated.

```
FILENAME=EMP_MFL, SUFFIX=DBFILE  ,
 DATASET=QSYS:SHIPPING/EMP, $
  SEGMENT=EMPINFOR, SEGTYPE=S0, $
    FIELDNAME=EMP_ID, ALIAS=EMP_ID, USAGE=A9, ACTUAL=A9,
      TITLE='EMP_ID', $
    FIELDNAME=LAST_NAME, ALIAS=LAST_NAME, USAGE=A10, ACTUAL=A10,
      TITLE='LAST_NAME', $
    FIELDNAME=FIRST_NAME, ALIAS=FIRST_NAME, USAGE=A10, ACTUAL=A10,
      TITLE='FIRST_NAME', $
    FIELDNAME=ADDRESS, ALIAS=ADDRESS, USAGE=A40, ACTUAL=A40,
      TITLE='ADDRESS', $
    FIELDNAME=RECFORM, ALIAS=EMPINFOR, USAGE=A10, ACTUAL=A10, $

  SEGMENT=PENSPATH, SEGTYPE=S0, PARENT=EMPINFOR, $
    FIELDNAME=EMP_ID, ALIAS=EMP_ID, USAGE=A9, ACTUAL=A9,
      TITLE='EMP_ID', $
    FIELDNAME=PLAN_NAME, ALIAS=PLAN_NAME, USAGE=A10, ACTUAL=A10,
      TITLE='PLAN_NAME', $
    FIELDNAME=VESTED, ALIAS=VESTED, USAGE=A1, ACTUAL=A1,
      TITLE='VESTED', $
    FIELDNAME=AMT_CNTRB, ALIAS=AMT_CNTRB, USAGE=P8.2, ACTUAL=P4,
      TITLE='AMT_CNTRB', $
    FIELDNAME=RECFORM, ALIAS=PENSPATH, USAGE=A10, ACTUAL=A10, $

  SEGMENT=VACPATH, SEGTYPE=S0, PARENT=PENSPATH, $
    FIELDNAME=EMP_ID, ALIAS=EMP_ID, USAGE=A9, ACTUAL=A9,
      TITLE='EMP_ID', $
    FIELDNAME=DAYS_EARND, ALIAS=DAYS_EARND, USAGE=P4.1, ACTUAL=P2,
      TITLE='DAYS_EARND', $
    FIELDNAME=DAYS_TAKEN, ALIAS=DAYS_TAKEN, USAGE=P4.1, ACTUAL=P2,
      TITLE='DAYS_TAKEN', $
    FIELDNAME=RECFORM, ALIAS=VACPATH, USAGE=A10, ACTUAL=A10, $
```

The internal field, RECFORM, is needed to reference a particular record format. (This is done automatically when you create the synonym.)

The RECFORM ALIAS is required, even for single format files, and must always have a value of the name of the record format.

DB Heritage Files Record Selection Efficiencies

The most efficient way to retrieve selected records from a data source is by applying an IF screening test against the primary key. This results in a direct reading of the data using the data source's index. Only those records that you request are retrieved from the file. The alternative method of retrieval, the sequential read, forces the adapter to retrieve all the records into storage.

Selection criteria that are based on the entire primary key, or on a subset of the primary key, cause direct reads using the index. A partial key is any contiguous part of the primary key beginning with the first byte.

IF selection tests performed against virtual fields can take advantage of these efficiencies as well, if the full or partial key is embedded in the virtual field.

The EQ and IS relations realize the greatest performance improvement over sequential reads. When testing on a partial key, equality logic is used to retrieve only the first segment instance of the screening value. To retrieve subsequent instances, NEXT logic is used.

Screening relations GE, FROM, FROM-TO, GT, EXCEEDS, IS-MORE-THAN, and NOT-FROM-TO all obtain some benefit from direct reads. The following example uses the index to find the record containing primary key value 66:

```
IF keyfield GE 66
```

It then continues to retrieve records by sequential processing, because DB Heritage Files stores records in ascending key sequence. The direct read is not attempted when the IF screening conditions NE, IS-NOT, CONTAINS, OMITS, LT, IS-LESS-THAN, LE, and NOT-FROM are used in the report request.

Reporting From Files With Alternate Indexes

Similar performance improvement is available for files that use alternate indexes. An alternate index provides access to records in a key sequenced data set based on a key other than the primary key.

All benefits and limitations inherent with screening on the primary or partial key are applicable to screening on the alternate index or partial alternate index.

Note: It is not necessary to take an explicit indexed view to use a particular index.

Chapter 21

Using the Adapter for Esri ArcGIS

The ESRI GIS Adapter is used to report against the information residing in the ESRI ArcGIS Online environment or on a locally hosted ArcGIS server. For example, Data Enrichment information for a specific ZIP code can be analyzed.

You can configure the ESRI GIS Adapter using the WebFOCUS Reporting Server Web Console. The adapter requires a connection, which stores the refresh token. A valid ESRI ArcGIS Online refresh token is required to issue ESRI ArcGIS Online API calls. This token is associated with an ESRI ArcGIS Online application and a specific ESRI ArcGIS Online user.

Note: To configure a named connection with the Adapter for Esri ArcGIS by clicking *Connect* on the WebFOCUS Home Page, the application server used by WebFOCUS and the WebFOCUS Reporting Server must both be running on the same machine. Otherwise, you cannot retrieve the refresh token for the adapter, and the Refresh Token field displays the text *Refresh Token unavailable*. In this case, configure the adapter from the Server Console, accessed through an HTTP listener, to acquire the token.

In this chapter:

Creating an ESRI ArcGIS Online Application

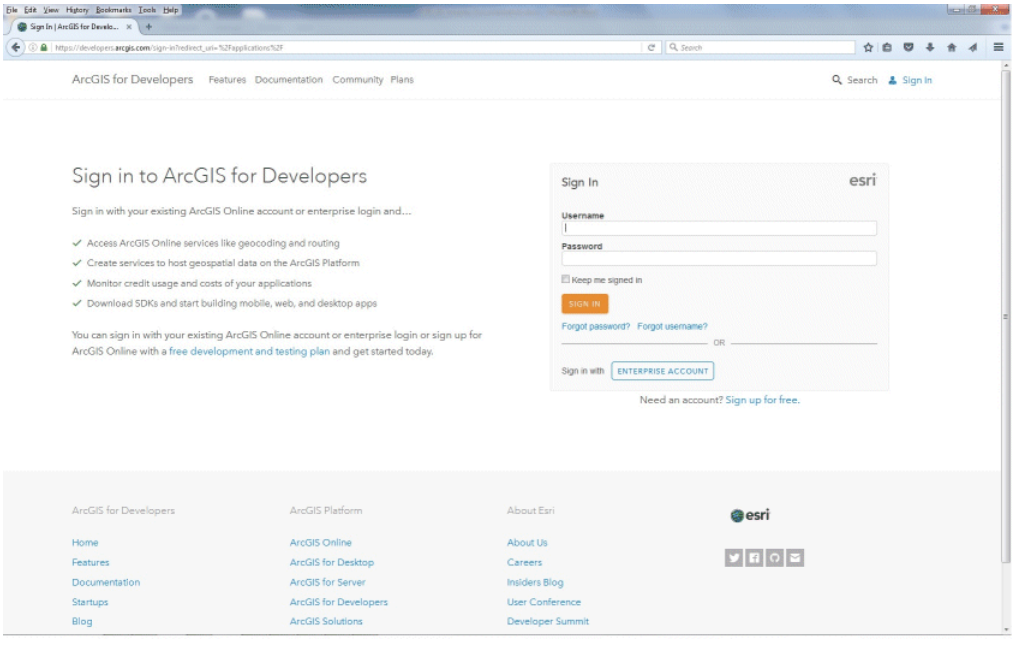
An ESRI ArcGIS Online application must be available before you can configure the ESRI GIS Adapter.

Procedure: How to Create an ESRI ArcGIS Application

1. Enter the following URL in a web browser:

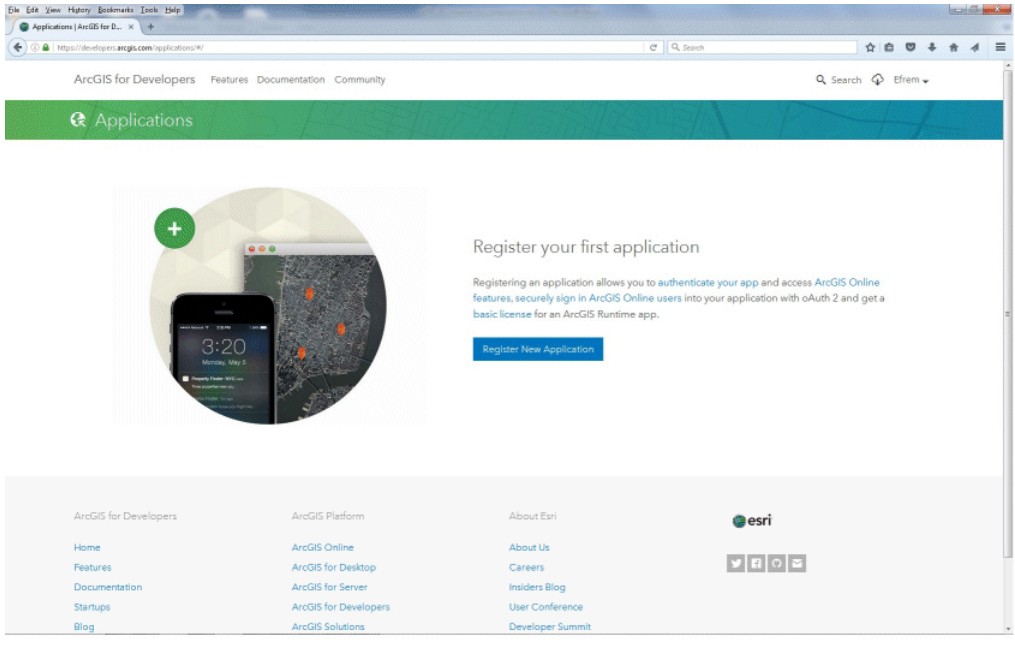
   `https://developers.arcgis.com/applications/#/`

If you are not already signed into the ESRI, a sign-in dialog for the ArcGIS for Developers site opens, as shown in the following image.



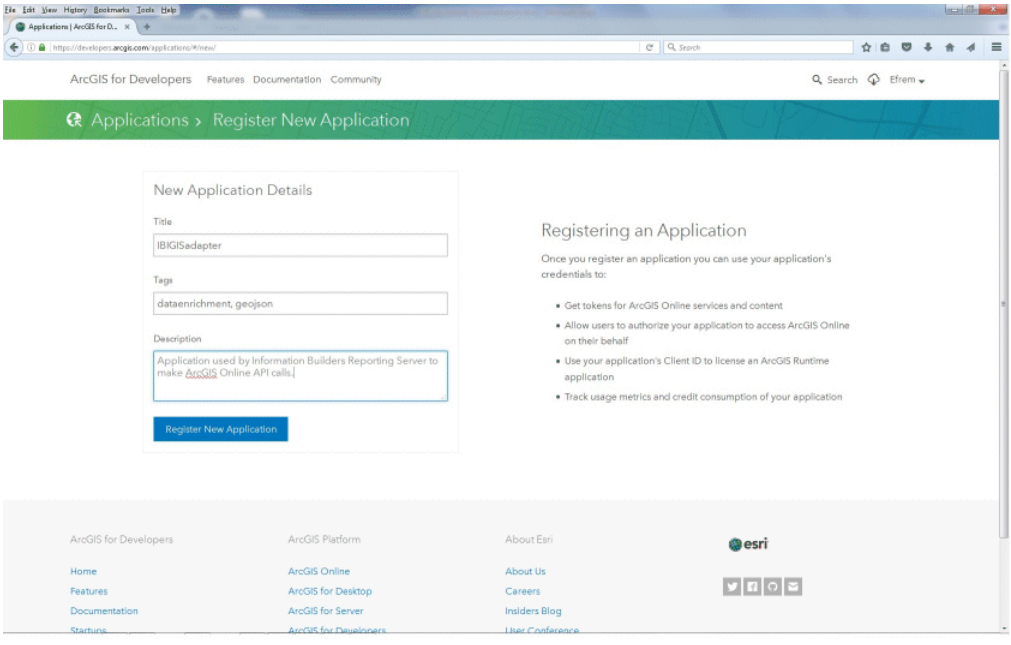
2. Enter valid ESRI ArcGIS Online account credentials that have the permission to create an ESRI ArcGIS Online application, and then click *Sign In*.

The Application screen opens, as shown in the following image.



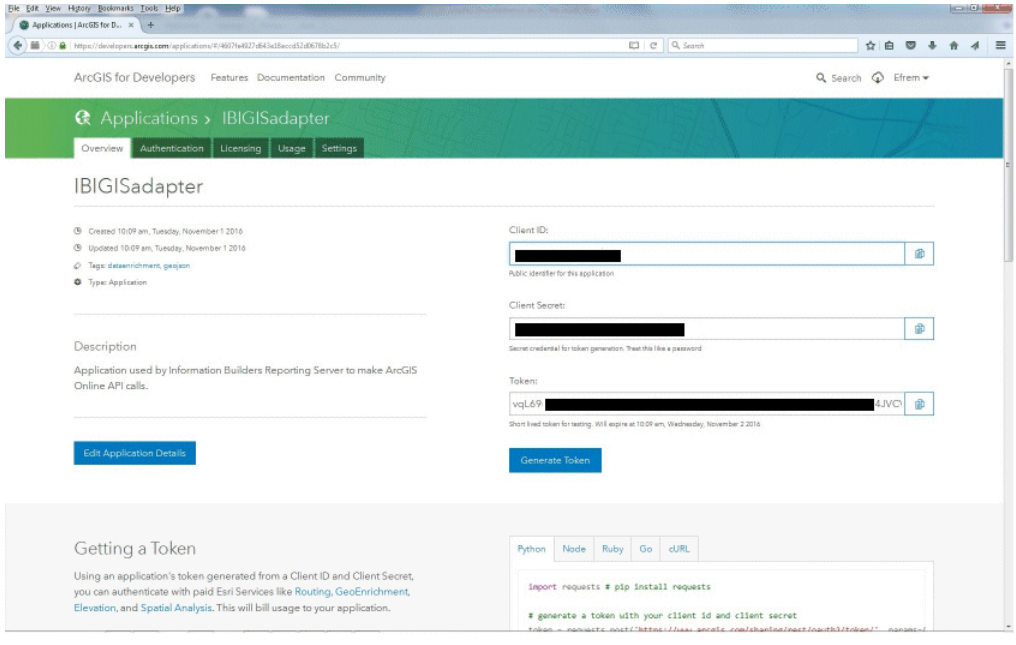
3. Click *Register New Application*.

The Register New Application screen opens, as shown in the following image.



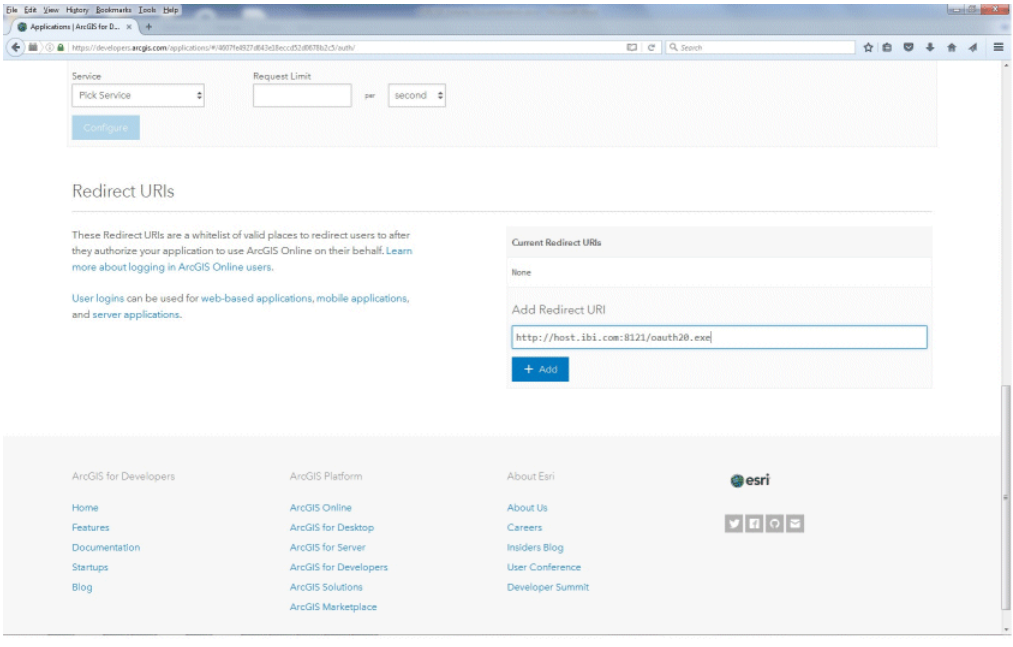
4. Enter a title, search tags, and a description for your new application and click *Register New Application*.

The Application Overview screen opens, which displays your Client ID and Client Secret values, as shown in the following image.



5. Click the *Authentication* tab.

Scroll down to the Redirect URIs section of the page, as shown in the following image.



6. Enter the host name and port used to access the Reporting Server Web Console appended with *oauth20.exe* in the Add Redirect URI field.

   For example:

   ```
   http://host.ibi.com:8121/oauth20.exe
   ```

   If the Reporting Server is installed as a standalone server, the following should be specified as the value in the Add Redirect URI field.

   ```
   http://localhost/oauth20.exe
   ```

7. Click + *Add*.

Configuring the Adapter for ESRI ArcGIS

This content describes how to configure the Adapter for ESRI ArcGIS.

Procedure: How to Configure the Adapter for ESRI ArcGIS for Non-Premium API Calls to ArcGIS Online

1. Clear cookies from the web browser that will be used to start the Reporting Server Web Console.

2. Access the Reporting Server Web Console using the host name and port that you specified in the Redirect URI field of the ESRI ArcGIS Online application.

   For example:

   ```
   http://host.ibi.com:8121
   ```

   For more information, see *Creating an ESRI ArcGIS Online Application* on page 599.

3. From the Web Console Applications page, click *Get Data*.

   or

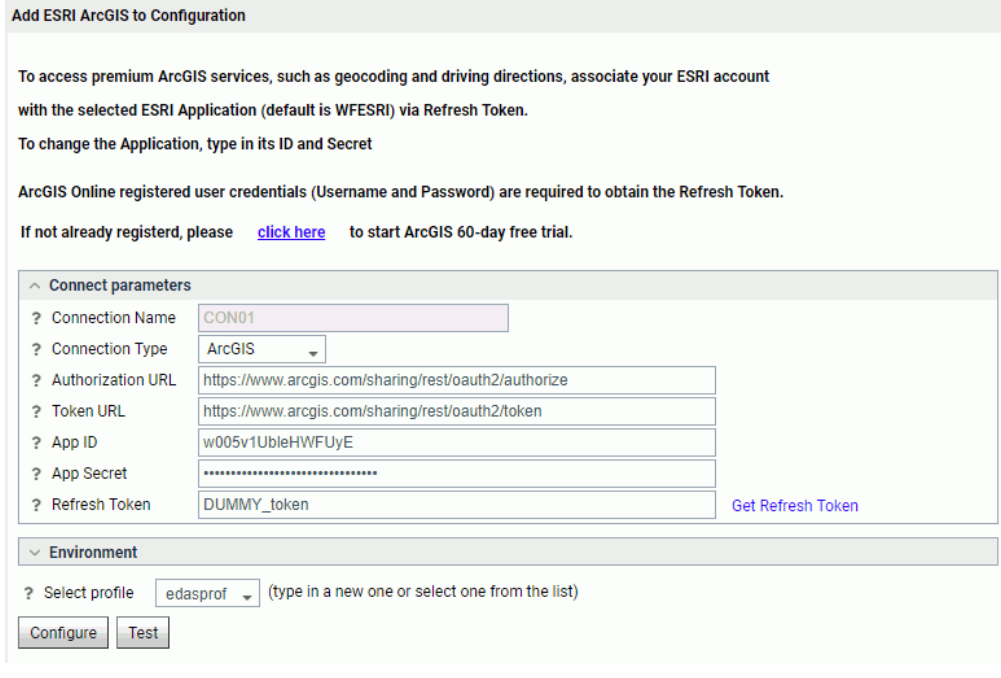
   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

4. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

5. Right-click the ESRI ArcGIS node and click *Add connection*.

   The Add ESRI ArcGIS to Configuration pane opens, as shown in the following image.

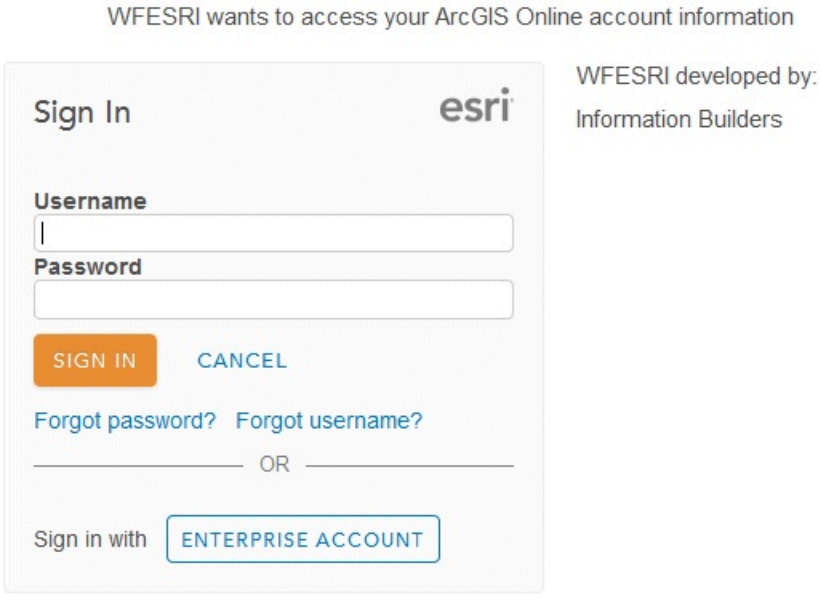


A default App ID and App Secret is prepopulated, to be used for the Non-Premium ESRI ArcGIS Online API calls covered in the Information Builders agreement.

Data Enrichment is included in the Premium ESRI ArcGIS Online API calls.

6. Click *Get Refresh Token*.

   The ESRI Sign In screen opens, as shown in the following image.



7. Enter the ESRI Sign In credentials and click *Sign In*.

   In order to obtain ESRI credentials, you can sign up at the following URL:

   https://developers.arcgis.com/sign-up/

   You are returned to the Add ESRI ArcGIS to Configuration pane where the Refresh Token is now populated.

8. Click *Configure*.

   The configured ESRI ArcGIS connection is added to the ESRI ArcGIS node in the left pane.

Procedure: How to Configure the Adapter for ESRI ArcGIS for Premium API Calls to ArcGIS Online

1. Clear cookies from the web browser that will be used to start the Reporting Server Web Console.

2. Access the Reporting Server Web Console using the host name and port that you specified in the Redirect URI field of the ESRI ArcGIS Online application.

   For example:

   ```
   http://host.ibi.com:8121
   ```

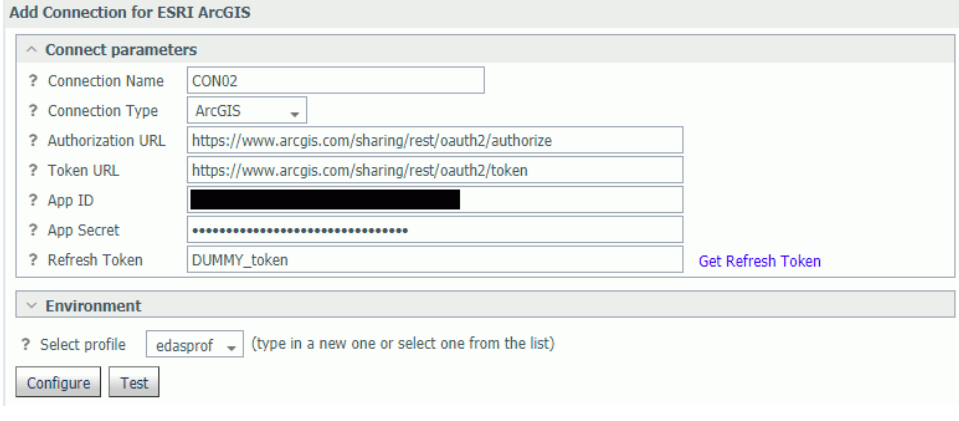
   For more information, see *Creating an ESRI ArcGIS Online Application* on page 599.

3. From the Reporting Server Web Console menu bar, click *Adapters*.

   The Adapters pane opens.

4. Expand the *Configured* folder, if it is not already expanded.
5. Expand the *GIS* folder.
6. Right-click the ESRI ArcGIS node and click *Add connection*, as shown in the following image.

   The Add Connection for ESRI ArcGIS pane opens, as shown in the following image.



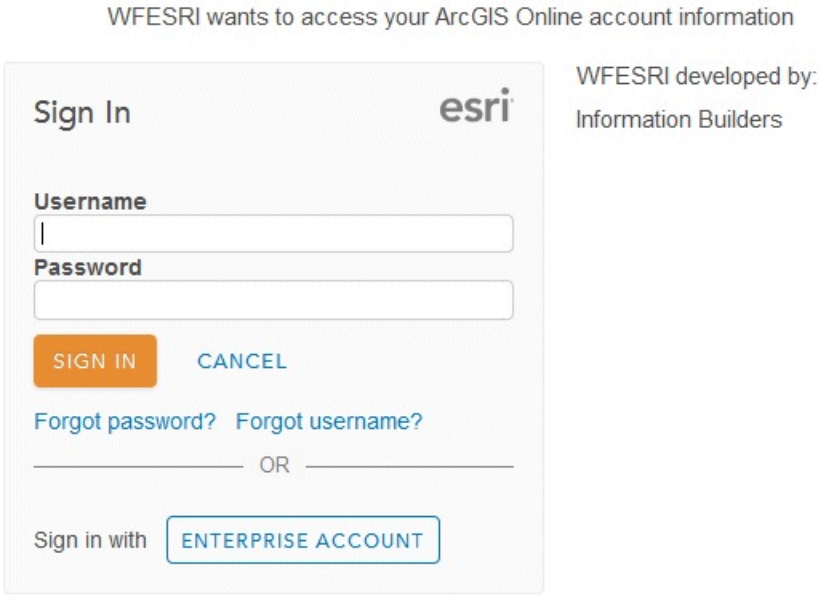
7. Enter the values for the App ID and App Secret defined in the ESRI application you created.

For more information, see *Creating an ESRI ArcGIS Online Application* on page 599.

Data Enrichment is included in the Premium ESRI ArcGIS Online API calls.

8. Click *Get Refresh Token*.

   The ESRI Sign In screen opens, as shown in the following image.



9. Enter the ESRI Sign In credentials and click *Sign In*.

   In order to obtain ESRI credentials, you can sign up at the following URL:

   https://developers.arcgis.com/sign-up/

   You are returned to the Add ESRI ArcGIS to Configuration pane where the Refresh Token is now populated.

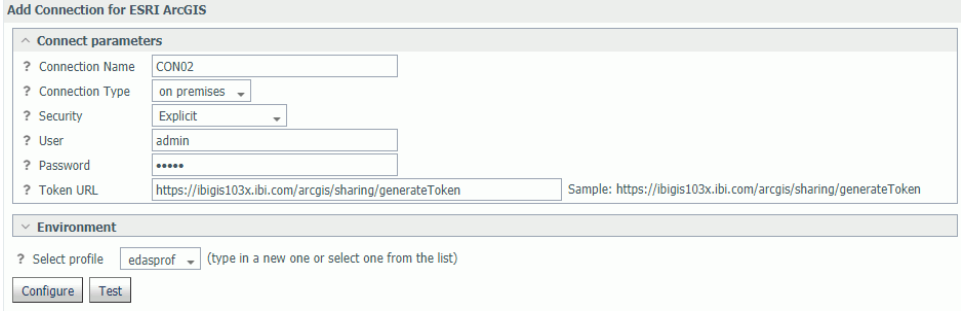
10. Click *Configure*.

    The configured ESRI ArcGIS connection is added to the ESRI ArcGIS node in the left pane.

Procedure: How to Configure a Locally Hosted ArcGIS Server

At some sites, ArcGIS Server is used in conjunction with or instead of ArcGIS Online. This type of configuration is called *Esri on Premise*.

1. When adding a connection for the Adapter for Esri ArcGIS, select *on premises* from the Connection Type drop-down list, as shown in the following image.



2. Select *Explicit* from the Security drop-down list.
3. Enter the user ID for the locally hosted ArcGIS Server in the User text box.
4. Enter the password for the locally hosted ArcGIS Server in the Password text box.
5. Enter the Token URL in the following format in the Token URL text box.

   `https://hostname/arcgis/sharing/generateToken`

   where:

   hostname

   Is the host where the ArcGIS Server is installed. For example:

   `https://ibigis103x.ibi.com/arcgis/sharing/generateToken`

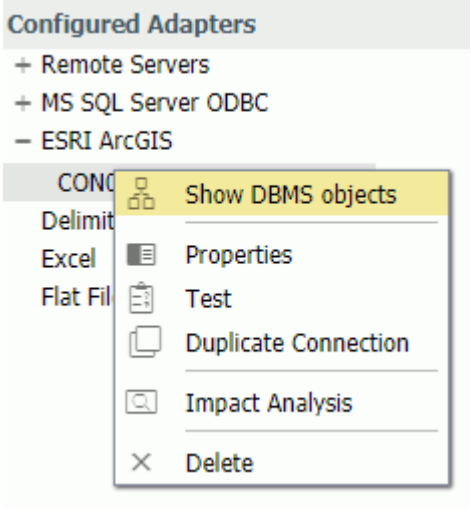
6. Test the connection by clicking *Test*.
7. When the test is successful, click *Configure*.

Creating Metadata and Sample Reports for the Adapter for ESRI ArcGIS Using Premium API Calls

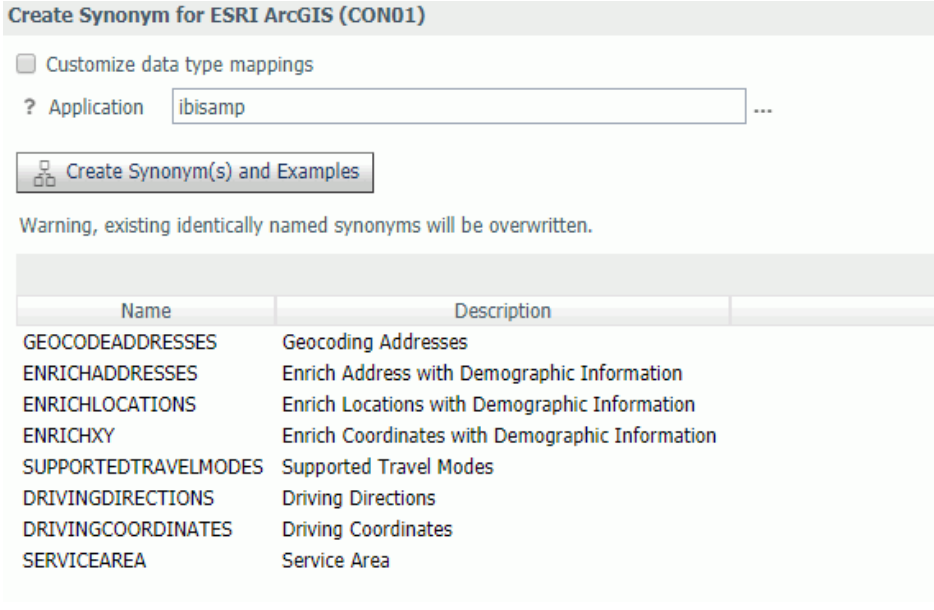
Create Synonym for the Adapter for ESRI ArcGIS creates the metadata and sample WebFOCUS reports used for WebFOCUS reporting against data returned from the Premium ESRI ArcGIS Online API calls.

Procedure: How to How to Create Metadata and Sample Reports for Premium API Calls

1. From the DMC, expand the *Adapters* folder, then the *Configured* folder, and then the *ESRI ArcGIS* folder.
2. Right-click the configured connection for the ESRI ArcGIS connection (for example, CON02) that has access to Premium ArcGIS Online API calls, and click *Show DBMS objects* from the context menu, as shown in the following image.



The Create Synonym for ESRI ArcGIS pane opens, as shown in the following image.



3. Enter a specific application in the Application field, or click the ellipsis button to the right of the field to select an application where the metadata and sample reports are to be stored.
4. Click *Create Synonym(s) and Example*s.

   The Create Synonym for ESRI ArcGIS Status pane opens and indicates that the synonym was created successfully.

Sample Metadata and Reports

This section describes the metadata and sample reports for the Adapter for ESRI ArcGIS.

Reference: Adapter for ESRI ArcGIS Metadata

Metadata	Description
drivingdirections	Driving directions between geocoded coordinates
enrichaddresses	Enriches a radius around an address with demographic information

Metadata	Description
enrichlocations	Enriches locations with demographic information (for example, ZIP codes)
enrichxy	Enriches a radius around a geocoded coordinate with demographic information
geocodeaddresses	Geocodes specific addresses
servicearea	Geocoded coordinates that can be serviced around a specific location
supportedtravelmodes	Valid travel modes

Reference: Adapter for ESRI ArcGIS Sample Reports

The following table lists and describes the sample reports for the Adapter for ESRI ArcGIS.

Sample Report	Description
esrsampl/drivingcoordinates	Returns a series of geocoded coordinates for the driving directions between geocoded coordinates. Uses drivingdirections synonym.
esrsampl/drivingdirections	Returns the driving directions between geocoded coordinates. Uses drivingdirections synonym.
esrsampl/enrich_wfretail_us	Ennriches a ZIP code from the Retail Sales Demo Data with demographic information. Uses enrichlocations synonym.
esrsampl/enrichaddresses	Enriches a radius around an address with demographic information. Uses enrichaddresses synonym.

Sample Report	Description
esrsampl/enrichlocations	Enriches one or more ZIP codes with demographic information. Uses enrichlocations synonym.
esrsampl/enrichxy	Enriches a radius around a geocoded coordinate with demographic information. Uses enrichxy synonym.
esrsampl/geocodeaddresses	Geocodes specific addresses. Uses geocodeaddresses synonym.
esrsampl/servicearea	Returns a list of geocoded coordinates that can be serviced around a specific location. Uses servicearea synonym.
esrsampl/supportedtravelmodes	Returns a list of supported travel modes. Uses supportedtravelmodes synonym.

Chapter 22

Using the Adapter for Essbase

The Adapter for Essbase allows applications to access Essbase data sources. The adapter converts application requests into native Essbase statements and returns optimized answer sets to the requesting application.

The Adapter for Essbase provides access to Hyperion Cubes from a server running on Microsoft Windows or UNIX. Essbase can only be accessed using an API supplied by the vendor. It is not possible to gain access using Direct SQL (Direct Passthru in server terminology) or the Adapter for ODBC.

Note: The level of User and Group Permissions for Applications/Databases required by Essbase 11.1.2 in order to be able to read the Database Outline was changed to the Access Database/Database Manager Level. All Reporting Server requests against Essbase read the Database Outline and, therefore, require this level of permissions.

In this chapter:

Preparing the Essbase Environment

The Adapter for Essbase minimally requires the installation of the Essbase Client. The Essbase Client allows you to connect to a local or remote Essbase Analytical Server.

Note: The level of User and Group Permissions for Applications/Databases required by Essbase 11.1.2 in order to be able to read the Database Outline was changed to the Access Database/Database Manager Level. All Reporting Server requests against Essbase read the Database Outline and, therefore, require this level of permissions.

Procedure: How to Prepare the Environment on Microsoft Windows

On Microsoft Windows, the Essbase environment is set up during the installation of Essbase.

Procedure: How to Prepare the Environment on UNIX

The following variables must be set during the installation of the Essbase Client:

ARBORPATH

Is the home directory for the Essbase Client.

For example, for the Essbase Client 11.1.2 on UNIX:

```
ARBORPATH= /rdbms5/arb11cli/EPMSystem11R1/products/Essbase/EssbaseClient
export ARBORPATH
```

ESSBASEPATH

Is the home directory for the Essbase Client (same as ARBORPATH).

For example, for the Essbase Client 11.1.2 on UNIX:

```
ESSBASEPATH= /rdbms5/arb11cli/EPMSystem11R1/products/Essbase/
EssbaseClient
export ESSBASEPATH
```

ESSLANG

Is the language setting for the Essbase Client.

For example, for the Essbase Client 11.1.2 on UNIX:

```
ESSLANG=English_UnitedStates.US-ASCII@Binary
export ESSLANG
```

LD_LIBRARY_PATH

Is the path for the Essbase Client libraries. LD_LIBRARY_PATH must include the bin directory under the Essbase Client home directory as well as the Essbase Client home directory, in that order.

For example, for the Essbase Client 11.1.2 on UNIX:

```
LD_LIBRARY_PATH =
/rdbms5/arb11cli/EPMSystem11R1/products/Essbase/EssbaseClient/bin;
/rdbms5/arb11cli/EPMSystem11R1/products/Essbase/EssbaseClient
export LD_LIBRARY_PATH
```

Configuring the Adapter for Essbase

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

When connecting to an Essbase Analytical Server, you must use Explicit authentication or Password passthru. This method requires that user IDs and passwords be explicitly stated in the SET CONNECTION_ATTRIBUTES command. You can include these commands in the server global profile, edasprof.prf, for all users. You can also issue the SET DEFAULT_CONNECTION command in the edasprof.prf file to select one of these connections as the default connection to use if the Access File does not include a server or connection name.

When you access an Essbase Analytical Server using the Reporting Server, you are identified by a user ID and password. The Database Administrator can assign management privileges to a specific user, where privileges:

- Are constant for all applications and databases.
- Apply to an application.
- Apply to a database.

For more information on security, see the *Hyperion Essbase* documentation.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Essbase

The *Essbase* adapter in under the *OLAP* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Server

Machine name where Essbase is running.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

The Password Passthru option requires that the server be started with DBMS security for Essbase Server authentication. See the *Server Administration* manual for information about configuring DBMS security.

User

User name by which you are known to the database.

Password

Password associated with the user name.

Outline Access

Existing connection name which is assumed to have Essbase Database Outline access and will be referenced by users having no Database Outline access privileges.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax:

How to Declare Connection Attributes Manually

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to Essbase, at connection time, for authentication.

```
ENGINE ESSBASE SET CONNECTION_ATTRIBUTES [connection]server
user/pwd
```

Password passthru authentication. The user ID and password are explicitly specified for each connection and passed to Essbase, at connection time, for authentication. This option requires that the server be started with security set to DBMS.

```
ENGINE ESSBASE SET CONNECTION_ATTRIBUTES [connection]server
```

where:

ESSBASE

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the server name used as a connect descriptor to the Essbase Server across the network.

server

Is the machine where Essbase is running.

userid

Is the primary authorization ID by which you are known to Essbase.

password

Is the password associated with the primary authorization ID.

Testing an Essbase Connection

Once connections have been defined in the edasprof.prf server global profile, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection, which is used if the Access File does not specify connection name or server. You can override this default using the SET DEFAULT_CONNECTION command.

Procedure: How to Test an Essbase Connection

There are two ways to access the Test function:

Right-click a connection and select *Test* from the pop-up menu.

or

1. Right-click a connection and select *Properties* from the pop-up menu.

   The Change Connect Parameters pane opens.

2. Click the *Test* button.

Managing Essbase Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Essbase data type.

Creating Synonyms

Synonyms define unique names for each Essbase *application.database* combination that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Essbase

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Select a database

Select one or more databases from the list.

Make alias fields

Select the *Make alias fields* check box if you wish to create fields that expose the values in your alias table. The alias table can provide meaningful field values or field values in a specific language.

Aggregate

This option enables you to control summing on non-aggregated fields in an Essbase request.

- Choose *On* to enable summing on non-aggregated fields.
- Choose *Off* to disable summing on non-aggregated fields. For additional information and syntax, see *Preventing Aggregation of Non-Consolidating Members* on page 644.

Select Measure

This option enables you to limit the number of fields in the Master File.

- Select *none* to create a single data value representing the cube measures.
- Select a dimension to create a separate numeric measure field for each member in that dimension.

  Note: If you select a dimension, you can select an additional dimension for grouping the measures.

Select Measure Group

If you selected a dimension to expose the measures, you can optionally select an additional dimension for grouping those measures.

Note: You can then select specific members to create as groups.

Measure Group members

If you selected a Measure Group, you can now select specific members for which to create groups.

1. Click the *Select Measure Group members* check box.
2. Click *Next*.

   A list of Scenario members displays.
3. Check the members that you want to create as groups. Check the *Scenario Name* check box to create groups for all members.

Synonym field name processing options:

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Synonym Name

To change the default name, type the name of the synonym.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Example: Creating a Synonym

To generate a synonym for the application *Sample* and database *Basic*, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. From the displayed list, select the row that contains the Application Name *Sample* and the Data Base Name *Basic*, then click the *Next* button.
2. Accept the default for *Measure*.
3. Click *Create Synonym*. The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays a message indicating that the synonym was created successfully.
4. Open the *baseapp* application folder in the navigation pane and click the synonym *Basic*.
5. Choose *Edit as Text* from the menu to view the generated Master File, then choose *Edit Access File as Text* to view the corresponding Access File.

```

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Using Default Field Names

The default field names that are used are taken from the generation names, if available, in the outline. Otherwise, they take the format

FIELDNAME=*generationnumber_dimensionname*

where:

generationnumber

Is the generation number within the dimension (for example, GEN2).

dimensionname

Is the name of the dimension.

For example, if the outline has a SCENARIO dimension, the first field name would be FIELDNAME=Scenario to represent the highest generation, the second field name would be FIELDNAME=GEN2_SCENARIO, and so on down the dimension hierarchy. For an illustration, see *Creating a Synonym* on page 624.

Reference: Access File Keywords

Keyword	Description
SERVER	Essbase Server name.
DBNAME=*database_name*	Indicates access to the specified database within an application.

Keyword	Description
APPLNAME=*application_name*	Indicates access to the specified application, which can contain one or more databases.

Parent/Child Support

The parent/child view in the Master File enables you to make requests using a member without having to know the generation to which the member belongs. The fields that provide this functionality are:

DIMENSION_MEMBER

Is the declaration for the field that contains the dimension members. It represents members of product at all levels of the dimension.

DIMENSION_CAPTION

Is the declaration for the field that contains the label displayed on reports for DIMENSION_MEMBER (this is the Essbase alias).

DIMENSION_PARENT

Is the declaration for the field that contains the parent of DIMENSION_MEMBER.

DIMENSION_PARENTCAP

Is the declaration for the field that contains the label displayed on reports for DIMENSION_PARENT (this is the Essbase alias).

The following is a sample of the parent/child view in the Master File:

```
FIELDNAME=SCENARIO_MEMBER, ALIAS=Scenario, USAGE=A10, ACTUAL=A10,
      WITHIN='*Scenario2',
      PROPERTY=UID,  $
    FIELDNAME=SCENARIO_CAPTION, USAGE=A10, ACTUAL=A10,
      REFERENCE=SCENARIO_MEMBER, PROPERTY=CAPTION,  $
    FIELDNAME=SCENARIO_PARENT, USAGE=A10, ACTUAL=A10,
      REFERENCE=SCENARIO_MEMBER, PROPERTY=PARENT_OF,  $
    FIELDNAME=SCENARIO_PARENTCAP, USAGE=A10, ACTUAL=A10,
      REFERENCE=SCENARIO_MEMBER, PROPERTY=CAP_PARENT,  $
```

Example: Using the Parent/Child View in the Master File

In the first request, Actual is explicitly identified with the generation GEN2_SCENARIO:

```
TABLE FILE BASIC
PRINT DATA_VALUE
WHERE GEN2_SCENARIO EQ 'Actual'
END
```

In the second request, which takes advantage of a parent/child view, Actual is represented as a member of the Scenario dimension. It is not necessary to know which generation it falls under.

```
TABLE FILE BASIC
PRINT DATA_VALUE
WHERE SCENARIO_MEMBER EQ 'Actual'
END
```

Both requests yield the same output:

```
DATA_VALUE = 105,522.00
```

Support for User-Defined Attributes

A User-Defined Attribute (UDA) in Essbase enables you to select and report on data based on a common characteristic. You can include UDAs in report requests. For each dimension with UDAs in an Essbase outline, synonym creation generates a UDA field name under a segment called UDA in the Master File.

Example: Reporting From a UDA Segment

The Sample Master File contains the following UDA segment:

```
$ DIMENSION: UDA
  SEGMENT=UDA, SEGTYPE=U, PARENT=BASIC, $
    FIELDNAME=MARKET_UDA, ALIAS=Market, USAGE=A13, ACTUAL=A13,
      REFERENCE=**Market, PROPERTY=UDA,  $
```

When referencing UDAs in a request, you must also reference a member of the dimension that contains the UDA. In this example, STATE is a member of the MARKET Dimension in the Master File.

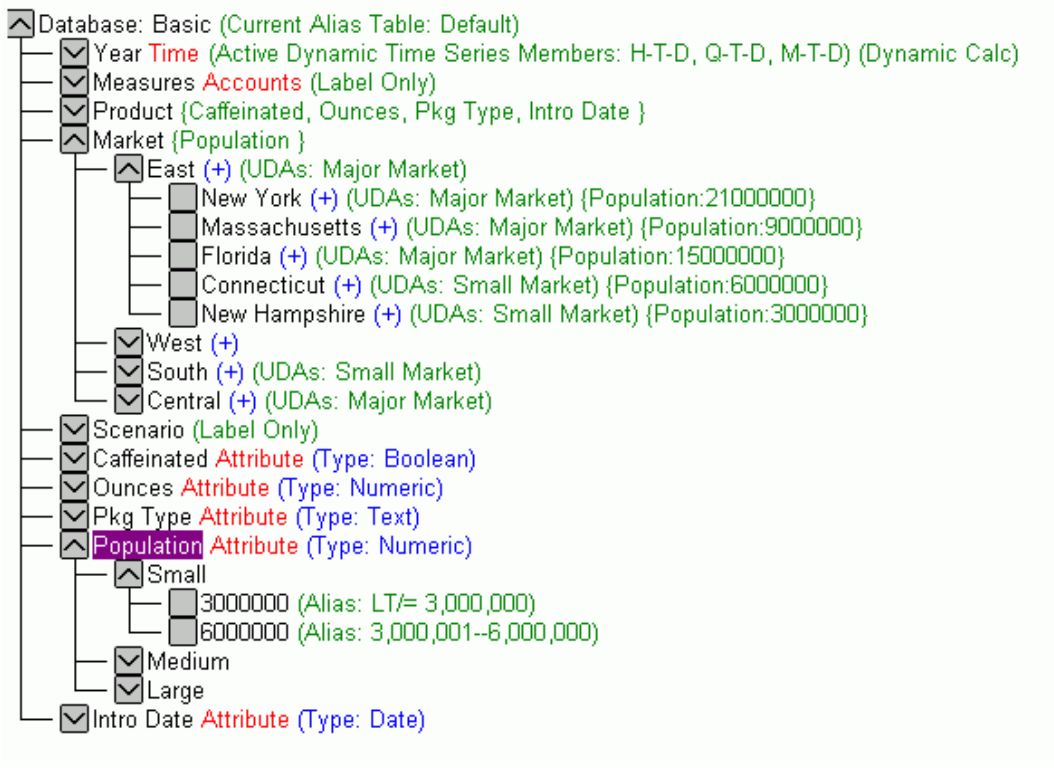
```
TABLE FILE BASIC
PRINT DATA_VALUE BY STATE
WHERE MARKET_UDA EQ 'New Market'
END
```

The output displays the values only for the states that have the UDA 'New Market' as a common characteristic:

```
STATE      DATA_VALUE
---------  ----------
Colorado     7,227.00
Louisiana    2,992.00
Nevada       4,039.00
```

Describing Attribute Dimensions in the Master File

An attribute dimension is identified by the word Attribute, which appears next to the Dimension name in the Essbase outline. Attribute dimensions are usually associated with standard Essbase dimensions. For example, in the following outline, Population is an Attribute dimension associated with the standard dimension Market.



The standard dimension serves as the base dimension for the associated attribute dimensions.

Example: Generating Attribute Dimensions

Synonym creation generates a Master File that contains an ATTR (attribute) segment, which defines attribute tagged dimensions.

The following is a portion of the Master File BASIC. Notice that Market is the base dimension with which the attribute dimension Population is associated.

```
FILENAME=SAMPLE, SUFFIX=ESSBASE ,$
  SEGMENT=BASIC, SEGTYPE=S0, $
>.
>.
>.
$  DIMENSION: Market
 DIMENSION=Market,CAPTION=Market, $
  HIERARCHY=Market,CAPTION=Market Levels,
     HRY_DIMENSION=Market,HRY_STRUCTURE=S, $
    FIELDNAME=MARKET, ALIAS='Gen1,Market', USAGE=A6, ACTUAL=A6,
      WITHIN='*Market', PROPERTY=UID,   $
    FIELDNAME=REGION, ALIAS=Region, USAGE=A7, ACTUAL=A7,
      WITHIN=MARKET,PROPERTY=UID, $

      REFERENCE=SKU, PROPERTY=UDA,  $
    FIELDNAME=POPULATION, ALIAS=Market, USAGE=A15, ACTUAL=A15,
      REFERENCE=STATE, PROPERTY=UDA,  $
    FIELDNAME=INTRO_DATE, ALIAS=Product, USAGE=A21, ACTUAL=A21,
      REFERENCE=SKU, PROPERTY=UDA,  $
```

The corresponding Access File contains any two-pass calculated members, as well as members with the following consolidation properties: (-0, (/), (*), (%). In addition, it contains the names of any shared dimension members. For an illustration, see *Reporting Against Attribute Tagged Dimensions* on page 633.

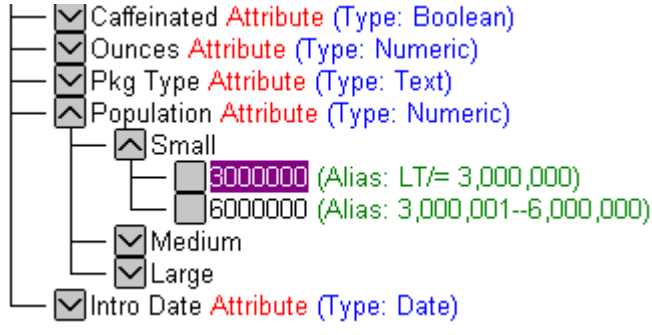
```
SEGNAME=BASIC, SERVER=edasol29, DBNAME=Basic, APPLNAME=Sample, $
 TIMEDIM=Year, $
 MEASURE=Measures, $
 MEMBER=COGS, AGGREGATE=NO, $
 MEMBER=TOTAL_EXPENSES, AGGREGATE=NO, $
 MEMBER=PROFIT_%, AGGREGATE=NO, $
 MEMBER=PROFIT_PER_OUNCE, AGGREGATE=NO, $
  SHARE=300-30, PARENT=Diet, DIM=Product, $
  SHARE=200-20, PARENT=Diet, DIM=Product, $
  SHARE=100-20, PARENT=Diet, DIM=Product, $
```

Example: Reporting Against Attribute Tagged Dimensions

This example uses data defined in the sample Master and Access Files in *Generating Attribute Dimensions* on page 631.

Note that using an Attribute Dimension as a BY field in a request is only supported with the MDX adapter (ENGINE ESSBASE SET MDX ON).

The following request references the Population attribute dimension in the ATTR segment of the Master File. The request also references a member of the Population attribute dimension, 3000000. Market is the base dimension for the Population attribute dimension.



The BY phrase in the request references STATE, which falls within the 3rd Generation (GEN=3) of the Market dimension. This reference is consistent with the following image in the Essbase outline.

The outline names the Base dimension (Market) and identifies the generation (GEN3) that you must reference within that Base dimension when you create an Essbase request using the specified member (3000000) of the Population attribute dimension.

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY STATE
WHERE POPULATION EQ '3000000'
END
```

The output is:

```
STATE           DATA_VALUE
-------------   ----------
Iowa              9,061.00
Nevada            4,039.00
New Hampshire     1,125.00
New Mexico          330.00
Utah              3,155.00
```

The next request generates a message because the generation of the referenced field, REGION, falls within the 2nd generation of the base dimension, Market, as shown in the previous outline.

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY REGION
WHERE POPULATION EQ '3000000'
END
```

As a result, the request displays the following message:

```
(FOC43271) Small_3000000 is not an associated attribute of any requested
column
```

Describing Measure Groups in the Master File

Measure groups in Essbase can be represented in two ways to the server: as normal dimensions or as pseudo accounts dimensions. If they are to be described as normal dimensions, the synonym creation process generates field descriptions for the dimension. If you wish to describe them as pseudo accounts in order to generate the measure group in place of the accounts dimension segment, use the SET SCENARIO command. You must issue the SET SCENARIO command before the synonym is created.

Syntax: How to Generate a Measure Group

If you wish to generate the Scenario dimension to be used in place of the accounts dimension segment, issue

```
ENGINE ESSBASE SET SCENARIO DIM dimension_name [member_name|ALL] FOR
synonym
```

where:

dimension_name

Is the measure group name.

When used in the SET SCENARIO command, *dimension_name* is case-sensitive and must match the case in the Essbase outline.

member_name

Specifies a member name in the measure group to be used to generate a field for every measure intersection. When used in the SET SCENARIO command, *member_name* is case-sensitive and must match the case in the Essbase outline.

ALL

Indicates that all members of the measure group are used to generate the Master File. ALL is the default value.

synonym

Is the Master File name for one *application.database* combination.

Note: You can issue the SET SCENARIO command multiple times to specify that a number of members from the measure group be used in the generation of the Master File. Once this command has been issued, you can create a synonym to generate the Master File name.

For each Measure group/Accounts member intersection, a field is generated in the Master File. If this multiplicity effect causes the Master File that is generated to be invalid (due to the total length of the fields), synonym creation fails and displays the following message:

```
Total actual or usage exceeds 32768 To cut down,try SET SCENARIO
```

If you receive this message, you will need to issue fewer SET SCENARIO commands to limit the scope of the Master File with regard to the number of measure groups used.

Describing the Measures Dimension in the Master File

The SET MEASURE command enables you to set or change the Accounts tagged dimension without having to change the outline in the Essbase Database Server. With this setting, the adapter produces an actual field name for every member of the named dimension in the Master File rather than producing the dimension in terms of generations. You must issue the SET MEASURE command before the synonym is created.

Syntax: How to Set or Change the Measures Dimension in the Master File

To set the Accounts tag for a dimension, issue

```
ENGINE ESSBASE SET MEASURE dimension_name FOR
synonym
```

where:

dimension_name

Is the name of the dimension to be interpreted as an Accounts tagged dimension when generating a synonym.

Generates a Master File in which the Accounts Tagged dimension is represented as generations.

synonym

Is the Master File name for one *application.database* combination.

Example: Using the SET MEASURE Command

The following command displays the actual member names of the measure group (for ACTUAL, BUDGET, or VARIANCE), rather than displaying fields like SCENARIO or GEN2_SCENARIO, in the Master File.

```
ENGINE ESSBASE SET MEASURE Scenario FOR SAMPLE
```

Reference: Limiting the Number of Fields in a Master File

SET MEASURE can be set to NONE. With this setting, all of the dimensions are interpreted as non-Accounts dimensions in the Master File and represented as generations.

In addition, a segment called DATA is added to the Master File. This segment contains a field called DATA_VALUE, which enables you to display the values of the Measures dimension although the actual member names are not present in the Master File.

Syntax: How to Limit the Number of Fields in a Master File

```
ENGINE ESSBASE SET MEASURE NONE FOR SAMPLE
```

where:

NONE

Generates a Master File in which the Accounts tagged dimension is represented as generations.

Example: Reporting Against a Master File With a Limited Number of Fields

If SET MEASURE has been set to NONE, you can display the values of the Measures dimension although the actual member names are not present in the Master File. The following is a sample DATA segment, which includes the field DATA_VALUE, against which you can report.

```
$  DIMENSION: DATA
  SEGMENT=DATA, SEGTYPE=U, PARENT=BASIC, $
    FIELDNAME=DATA_VALUE, ALIAS=DATA_VALUE, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, TITLE='DATA_VALUE', $
TABLE FILE BASIC
PRINT DATA_VALUE
BY PRODUCT
END
```

The output is:

```
PRODUCT             DATA_VALUE $
-------------       -------------------
Product             105,522.00
```

Changing the Default Usage Format of the Accounts Dimension

All dimension descriptions in the Master File, except for the accounts dimension, have the USAGE format of alphanumeric. The default format of the accounts dimension is D20.2. You can change this default using the SET CONVERSION command.

Syntax: How to Change the Default Usage Format of the Accounts Dimension

```
ESSBASE SET CONVERSION format PRECISION n m
```

where:

format

Possible values are:

FLOAT which indicates that the command applies only to double precision floating point columns.

DECIMAL which indicates that the command applies only to decimal columns.

n

Is the precision. It must be a valid number representing the maximum value for precision for the data type.

m

Is a valid number representing the maximum value for scale for the data type.

If you do not specify a value for scale, the current scale setting remains in effect. If the scale is not required, you must set *m* to 0 (zero).

Customizing the Essbase Environment

The Adapter for Essbase provides several parameters for customizing the environment and optimizing performance. The following topics provide an overview of customization options.

Using the MDX Adapter

Essbase Version 7 makes an interface available that communicates with the Essbase engine using MDX instead of the Essbase proprietary query language. If you issue the SET MDX ON command in any supported profile, the Adapter for Essbase will submit queries to Essbase using MDX.

The MDX version of the Adapter for Essbase provides the following capabilities:

- There is no default limit or maximum for the number of rows returned by a query. Therefore, the MAXROWS setting is not needed.
- You gain additional functionality for attribute dimensions, which are groups of properties that apply to a specific level-based field. An attribute dimension is stored as a flat hierarchy (all of the members are stored on a single level immediately below the dimension name in the synonym).

  Attribute dimensions can be used as filters in a query whether it is based on level hierarchies or parent/child hierarchies. In order to use the not-equal operator with an attribute dimension, you must use a WHERE TOTAL phrase rather than a WHERE phrase.

  With a level hierarchy, an attribute dimension can also be used as a BY field, as long as the field to which it is linked is also a BY field in the request.

Syntax: How to Enable the MDX Adapter for Essbase

```
ENGINE ESSBASE SET MDX {ON|OFF}
```

where:

`ON`

Enables the MDX adapter.

`OFF`

Uses the native adapter for Essbase. OFF is the default value.

Specifying ALIAS Names

In Essbase, you can assign more than one name to a member or a shared member. For example, in the *Sample.Basic* database, the PRODUCT dimension contains members that can be identified by both product codes, such as 200, or by more descriptive names, such as COLA. By default, the output values for members specified in a request are the member values. The server allows you to take advantage of the more descriptive member names in the Essbase outline when formulating a request.

Syntax: How to Specify ALIAS Names in a Request

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET USEALIASNAME {ON|OFF} [FOR synonym]
```

where:

`ON`

Allows the use of ALIAS names in a request.

`OFF`

Does not allow the use of ALIAS names in a request. OFF is the default value.

`synonym`

Is the Master File name for one *application.database* combination.

Note: If the SET USEALIASNAME command is used without FOR *synonym*, the setting applies to all Master Files. If the *synonym* option is used, the setting applies only to that Master File. You can issue multiple commands to control the use of the ALIAS name at the Master File level.

In an Essbase script, the reporting keyword OUTALTNAMES is equivalent to ALIAS.

Specifying ALIAS and Member Names in One Request

Procedure: How to Specify ALIAS and Member Names in a Request

When creating the synonym, check the *Make alias fields* check box to create a Master File that contains an alias field for each field in the generation view. For information on creating synonyms, see *Creating Synonyms* on page 620.

Example: **Generated Master File basic.mas**

```
FILENAME=SAMPLE, SUFFIX=ESSBASE, $
SEGMENT=BASIC, SEGTYPE=S0, $
.
.
.
 $  DIMENSION: Product
 DIMENSION=Product,CAPTION=Product, $
  HIERARCHY=Product,CAPTION=Product Levels,
      HRY_DIMENSION=Product,HRY_STRUCTURE=S, $
    FIELDNAME=PRODUCT, ALIAS='Lev2,Product', USAGE=A7, ACTUAL=A7,
      WITHIN='*Product', $
    FIELDNAME=FAMILY, ALIAS=Family, USAGE=A4, ACTUAL=A4,
      WITHIN=PRODUCT, $
    FIELDNAME=FAMILY_ALIAS, ALIAS=Family_ALIAS, USAGE=A11, ACTUAL=A11,
      REFERENCE=FAMILY, PROPERTY=CAPTION,  $
    FIELDNAME=SKU, ALIAS=SKU, USAGE=A6, ACTUAL=A6,
      WITHIN=FAMILY, $
    FIELDNAME=SKU_ALIAS, ALIAS=SKU_ALIAS, USAGE=A18, ACTUAL=A18,
      REFERENCE=SKU, PROPERTY=CAPTION,  $
```

Note: The SET USEALIASNAME ON/OFF command is ignored when the Master File is created using this option.

For information about the SET USEALIASNAME command, see *Specifying ALIAS Names* on page 639.

Using ALIAS and Member Names in an Essbase Request

```
TABLE FILE BASIC
PRINT SALES PROFIT_K
BY SKU
BY SKU_ALIAS
WHERE SKU_ALIAS EQ 'Cola'
END
```

The output is:

```
SKU      SKU_ALIAS   Sales      Profit
---      ---------   -------    --------
100-10   Cola        62,824.00  22,777.00
```

Specifying ALIAS Tables

In Essbase, aliases are generally stored in one or more tables as part of the database outline. Once the SET command is active, screening conditions must use the ALIAS value, not the member value.

If multiple ALIAS tables exist for an outline, you can use the SET ALIASTABLE command to specify which ALIAS table to use for a query.

Syntax: How to Specify an ALIAS Table

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET ALIASTABLE {aliastablename|RESET} FOR synonym
```

where:

aliastablename

Is the ALIAS table name to be used.

RESET

Sets the alias table back to the current default for the outline in Essbase.

synonym

Is the Master File name for one *application.database* combination.

Note: This SET ALIASTABLE command is used in conjunction with the SET USEALIASNAME command. If that command is not issued, the SET ALIASTABLE command is ignored. For more information, see *Specifying ALIAS Names* on page 639.

Setting the Maximum Number of Rows Returned

The default number of rows that can be returned from an Essbase cube using the server is 10,000. This can be controlled by the MAXROWS setting, which can be set in any supported server profile.

Note: The MAXROWS setting does not apply to the MDX Adapter, which has no default limit and no maximum number of rows returned.

Syntax: How to Set the Maximum Number of Rows Returned

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

To limit or extend the number of rows returned, use the syntax

```
ENGINE ESSBASE SET MAXROWS n [FOR synonym]
```

where:

n

Is a valid number that either limits or extends the number of rows to be returned. The default number of rows returned without this setting is 10,000. The maximum number for this setting is 999999999.

synonym

Is the Master File name for one *application.database* combination.

Time Series Reporting

By using Time Series and Accounts tags within your Essbase outline, you can tell Essbase how to calculate your accounts data. When you tag a dimension as Time, Essbase knows that this is the dimension on which to base the time periods for the Accounts tags.

The server supports all eight levels of period-to-date reporting within Essbase. See the *Hyperion Essbase Database Administrator's Guide* for further information.

In order to retrieve values from members in an Accounts dimension using time-series reporting, you must refer to at least one member of the Time dimension using the WHERE clause.

Example: Using Time Series Reporting

```
TABLE FILE BASIC
PRINT PRODUCT Q_T_D PROFIT_K AS 'Profit'
WHERE Q_T_D EQ 'Mar'
END
```

Where PROFIT_K is a member of the Accounts dimension, PRODUCT is a member of a non-Accounts dimension, and Q_T_D is a member of the Time dimension. The above request returns the following row:

```
Product Q-T-D(Mar)            24703.00
```

Note: All results reference the Dynamic Time series member with dashes between letters.

The equivalent request using SQL is:

```
SELECT Q_T_D, PRODUCT, PROFIT_K FROM BASIC WHERE Q_T_D = 'Mar'
```

Summing on Non-Aggregated Fields

The Essbase outline can contain two-pass calculated members, as well as members with different consolidation properties. Any two-pass calculated members that are found in the accounts (or Scenario) dimension members with the (-), (\), (*), and (%) consolidation properties in the Essbase outline, have the following attributes in the associated Access File:

```
MEMBER=membername, AGGREGATE=NO, $
```

By default (when Aggregation is ON), you cannot use the SUM command on two-pass calculated members or on members with the (-), (\),(*), and (%) consolidation properties. If a request contains a SUM action that uses one of these members, the following error message is displayed:

```
(FOC43241) Aggregation is requested for non aggregatable member(s)
```

However, when Aggregation is turned OFF, the server allows SUM to be used on two-pass calculated members and members with the (-), (\),(*), and (%) consolidation properties.

Syntax: How to Turn Aggregation ON/OFF For Non-Aggregated Fields

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET RESTRICTSUM [ON|OFF] FOR synonym
```

where:

`ON`

Does not allow the use of SUM on non-aggregated fields. ON is the default value.

`OFF`

Allows the use of SUM on non-aggregated fields.

`synonym`

Is the Master File name for one *application.database* combination.

Example: Using RESTRICTSUM on Non-Aggregated Fields

Using this Access File

```
SEGNAME=BASIC, SERVER=unxsol26, DBNAME=Basic, APPLNAME=Sample, $
TIMEDIM=Year, $
MEASURE=Measures, $
MEMBER=COGS, AGGREGATE=NO, $
MEMBER=TOTAL_EXPENSES, AGGREGATE=NO, $
MEMBER=PROFIT_%, AGGREGATE=NO, $
MEMBER=PROFIT_PER_OUNCE, AGGREGATE=NO, $
```

issue the following request:

```
TABLE FILE BASIC
SUM COGS
BY QUARTER
END
```

If RESTRICTSUM ON (default) is set in the profile, the following message is displayed and no output is generated:

```
(FOC43241) Aggregation is requested for non aggregatable member(s)
```

If you set RESTRICTSUM OFF in the profile, SUM is permitted on non-aggregated fields, producing this output:

```
QUARTER                    COGS
-------                 ---------
Qtr1                    42,877.00
Qtr2                    45,362.00
Qtr3                    47,343.00
Qtr4                    43,754.00
```

Preventing Aggregation of Non-Consolidating Members

Member consolidation properties determine how children roll up into their parents in the Essbase outline. The members with the (~) as a consolidation property in the Essbase outline, are *not* rolled up in the database. The SET AGGREGATE NOOP (No Operation) setting only affects those Essbase members in the Accounts dimension with the (~) consolidation property. If AGGREGATE NOOP is set to OFF, SUM is not permitted on Essbase members with the (~) consolidation property and those members appear in the Access File as:

```
MEMBER=ADDITIONS, AGGREGATE=NO, $
```

Syntax: How to Prevent Aggregation of Non-Consolidating Members

You must turn set AGGREGATE NOOP to OFF before you create the synonym.

```
ENGINE ESSBASE SET AGGREGATE NOOP {ON|OFF}
```

where:

ON

Allows the use of SUM on NOOP Essbase members. With this setting, Essbase members are not added to the Access File. ON is the default value.

OFF

Does not allow the use of SUM on NOOP Essbase members. Members with the (~) consolidation property are added to the Access File.

Note: Any member of the Accounts dimension in the Essbase outline tagged with (-), (/), (*), or (%) as a consolidation property automatically appears in the Access File with the AGGREGATE=NO setting.

Suppressing Shared Members

Shared Members in Essbase store pointers to data that is stored in the real member. Therefore, although the data is shared between the two members, it is only stored one time. You can exclude shared members from reports using the SUPSHARE setting.

Syntax: How to Suppress Shared Members in Essbase

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET SUPSHARE [ON|OFF]
```

where:

`ON`

Excludes shared members in a report.

`OFF`

Includes shared members in a report. OFF is the default value.

Example: Suppressing Shared Members

The following request and output illustrates the affect of turning SUPSHARE OFF and ON.

```
TABLE FILE SAMPLE
PRINT SALES BY FAMILY BY SKU
AND COLUMN-TOTAL
WHERE FAMILY EQ 'Diet' OR '200'
END
```

With SUPSHARE OFF, the output is:

```
FAMILY  SKU         SALES
------  ------  ---------
200     200-10  41,537.00
        200-20  38,240.00
        200-30  17,559.00
        200-40  11,750.00
Diet    100-20  30,469.00
        200-20  38,240.00
        300-30  36,969.00
=========================
TOTAL          214,764.00
```

With SUPSHARE ON, the output is:

```
FAMILY  SKU         SALES
------  ------  ---------
200     200-10  41,537.00
        200-20  38,240.00
        200-30  17,559.00
        200-40  11,750.00
Diet    100-20  30,469.00
        300-30  36,969.00
=========================
TOTAL          176,524.00
```

Notice that member 200-20 is displayed twice in the first report, but only once in the second report. Turning SUPSHARE ON prevents a shared member from being duplicated in a report request.

Suppressing Zero Values

Essbase stores zero values that you can exclude from reports using the SUPZEROS setting. This setting applies to an entire row. If one member in a row has a value of zero, and the other values in the same row have values other than zero, the zero value will not be suppressed.

Syntax: How to Suppress Rows With Zero Values

```
ENGINE ESSBASE SET SUPZEROS [ON|OFF]
```

where:

`ON`

Suppresses an entire row that contains 0 values.

`OFF`

Does not suppress zero values. OFF is the default value.

Example: Suppressing Zero Values

The following output illustrates the affect of turning SUPZEROS OFF and ON.

With SUPZEROS OFF, the output is:

```
STATE           SALES      PROFIT
---------    ---------   ---------
Colorado    38,240.00   42,877.00
Louisiana   0.00        0.00
Nevada      29,156.00   47,343.00
```

With SUPZEROS ON, the output is:

```
STATE           SALES     PROFIT
--------    ---------  ---------
Colorado    38,240.00  42,877.00
Nevada      29,156.00  47,343.00
```

Suppressing Missing Data

In Essbase, empty cells are known as missing or #MISSING data. You can suppress missing data during reporting using the SUPMISSING setting.

Syntax: How to Suppress Rows With Missing Data

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET SUPMISSING [ON|OFF]
```

where:

`ON`

Suppresses an entire row that contains #MISSING data.

`OFF`

Does not suppress rows with #MISSING data. OFF is the default value.

Example: Suppressing Missing Data

The following output illustrates the affect of turning SUPMISSING OFF and ON.

With SUPMISSING OFF, the output is:

```
STATE           SALES     PROFIT
---------   ---------  ---------
Colorado    38,240.00  42,877.00
Louisiana   #MISSING   #MISSING
Nevada      29,156.00  47,343.00
```

With SUPMISSING ON, the output is:

```
STATE           SALES     PROFIT
--------    ---------  ---------
Colorado    38,240.00  42,877.00
Nevada      29,156.00  47,343.00
```

Suppressing Zero Values and Missing Data

You can use the SUPEMPTY setting to suppress an entire row that contains either zero values, missing (#MISSING) data, or a combination of the two.

Syntax: How to Suppress Rows With Zero Values or Missing Data

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET SUPEMPTY [ON|OFF]
```

where:

`ON`

Suppresses an entire row that contains either zero values, #MISSING data, or a combination of the two.

`OFF`

Does not suppress rows that contain either zero values or #MISSING data. OFF is the default value.

Example: Suppressing Rows With Zero Values or Missing Data

The following output illustrates the affect of turning SUPEMPTY OFF and ON.

With SUPEMPTY OFF, the output is:

```
STATE           SALES     PROFIT
---------    ---------  ---------
Colorado     38,240.00  42,877.00
Louisiana    #MISSING   #MISSING
Nevada       0.00       0.00
```

With SUPEMPTY ON, the output is:

```
STATE           SALES     PROFIT
--------     ---------  ---------
Colorado     38,240.00  42,877.00
```

Substitution Variables

Substitution variables act as global placeholders for information that changes regularly. Each substitution variable configured in Essbase is assigned a value. You can change the value at any time, thus limiting the number of manual changes required in your scripts when you are running reports.

When you reference an Essbase substitution variable in a TABLE command, the substitution variable must be preceded with an up arrow (^) and enclosed in single quotation marks.

Example: Using a Substitution Variable in a Request

In this example, CurrMonth is the name of the substitution variable that was set in Essbase. The ^ and quotation marks are required.

```
TABLE FILE BASIC
PRINT Product
BY
PRODUCT
WHERE
MONTH EQ '^CurrMonth'
END
```

Using the SPARSE Data Extraction Method

The SET SPARSE ON command tells Hyperion Essbase to use the sparse data extraction method, which optimizes performance when a high proportion of the reported data rows are #MISSING. This data extraction method is different from the regular method. Hyperion Essbase cannot use the sparse data retrieval optimization method on Dynamic Calc or Dynamic Calc And Store members.

Syntax: How to Use the SPARSE Data Extraction Method

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE ESSBASE SET SPARSE {ON|OFF}
```

where:

`ON`

Uses the sparse data extraction method when a high proportion of the reported data rows are #MISSING.

`OFF`

Does not use the sparse data extraction method. OFF is the default value.

Setting a Default Connection

Once connections have been defined in the edasprof.prf server global profile, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection, which is used if the Access File does not specify connection name or server. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE ESSBASE SET DEFAULT_CONNECTION connection
```

where:

`ESSBASE`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE ESSBASE SET DEFAULT_CONNECTION SAMPLE
```

Supporting Unicode Mode Applications

An Essbase application can be set to work in Unicode or non-Unicode mode. If the Reporting Server is configured for Unicode, no setting is required to use a cube set for Unicode mode in a Unicode mode application. However, if the server is not configured for Unicode but your Essbase cube is configured for Unicode, you must issue the ENGINE ESSBASE SET UNICODE ON command.

Syntax: How to Configure the Adapter for Unicode Mode Applications

```
ENGINE ESSBASE SET UNICODE {OFF|ON}
```

where:

OFF

Does not support Unicode mode applications when the server is not configured for Unicode. OFF is the default value.

ON

Supports Unicode mode applications when the server is not configured for Unicode.

Syntax: How to Determine Whether Unicode Mode Applications Are Supported

```
ENGINE ESSBASE SET ?
```

When you issue this command, the following message indicates whether Unicode mode is on for your Essbase cube:

```
(FOC43249) Essbase Unicode Option : on
```

Essbase Reporting With WebFOCUS

Overview of Essbase Reporting Concepts

In a multi-dimensional data source (cube), dimensions are categories of data, such as Region or Time, that you use to analyze and compare business performance. Dimensions consist of data elements that are called *members*. For example, a Region dimension could have members *England* and *France*.

Dimension members are usually organized into hierarchies. Hierarchies can be viewed as tree-like graphs where members are the nodes.

For example, the Region dimension may have the element *World* at its top level (the root node). The World element may have children nodes (members) representing continents. Continents, in turn, can have children nodes that represent countries, and countries can have children nodes representing states or cities. Nodes with no children are called *leaf nodes*.

Measures are numeric values, such as Sales Volume or Net Income, that are used to quantify how your business is performing.

A multi-dimensional cube consists of data derived from facts, which are records about individual business transactions. For example, an individual fact record reflects a sales transaction of a certain number of items of a certain product at a certain price, which occurred in a certain store at a certain moment of time. The cube contains summarized fact values for all combinations of measures and members of different dimensions.

For example, the following combination (*tuple*) contains the total volume of sales of pumps in all stores in England in 2005:

```
{Sales Volume, Pumps, England, 2005}
```

The point in the cube that contains this summarized value is called a cell. A cell is addressed by a combination of members of different dimensions and a measure. In this example *Sales Volume* is a measure and *Pumps*, *England*, and *2005* are members of the Product, Region, and Time dimensions respectively.

Individual fact records are usually tied to the leaf nodes of each hierarchy in the cube. The fact values get included in cells addressed by these leaf nodes and added to all cells addressed by all combinations of ascendants of these leaf nodes along each hierarchy of the cube.

The operation used to summarize facts for some measures can be a simple sum or a more complex aggregation function such as an average.

In Essbase, it is assumed that a value exists for each combination of hierarchy values contained in the cube. Measures are not represented separately until the metadata is created. At that time you have the choice of simply creating a "cell" value tied to the existing combinations or exposing one or two of the dimensions as the measures.

Some combinations of hierarchy nodes may not have any fact records tied to them. The cells addressed by these combinations are empty cells.

As illustrated in the previous example, a tuple is a combination of members from different dimensions of a cube. The previous tuple contains members from all dimensions and, therefore, addresses a single cell. If a tuple contains only members from some dimensions, it addresses not just one cell but a whole slice of cells in the cube. For example, the following tuple does not include either Region or Time dimension members:

```
{Sales Volume, Pumps}
```

It addresses as many cells in the cube as there are members of the Region dimension times the number of members of the Time dimension.

The number of cells in the cube addressed by a single dimension member is a product of cardinalities of all other dimensions.

When all cells addressed by a member are empty, the member is called an empty member. When all cells addressed by a tuple are empty, the tuple is called an empty tuple.

By default, empty cells appear on report output. You can issue the following command if you want to eliminate them on the report output:

```
ENGINE ESSBASE SET SUPMISSING ON
```

Cubes can also include two types of attributes, which are parameters used in data selection. Attributes cannot be displayed or used for sorting; they can only be used in selection criteria.

When the adapter accesses a multi-dimensional cube, it uses two types of metadata elements about dimensions:

- **Hierarchy fields.** These fields contain data that apply to a specific hierarchy and describe the position of each member within that hierarchy. For example, these fields identify the parent of the member, as well as its own name, caption, and unique ID.
- **Dimension properties.** These fields contain data that potentially apply to all members of the dimension. For example, a Region dimension may have a property called GEOGRAPHICAL_HEIGHT that specifies the altitude for each member of the Region dimension.

Using the hierarchy fields, the adapter can recreate the hierarchy and locate portions of the hierarchy needed to satisfy a request.

Understanding Columnar and Hierarchical Reporting

Two types of hierarchy are represented in a synonym: level and parent/child.

A synonym describes a level hierarchy by using a separate field for each level. To report on a level hierarchy, you use columnar reporting in which you specify the field name for each level you want to display.

A synonym describes a parent/child hierarchy using a set of fields that define the hierarchical structure and the relationships between the hierarchy members. The adapter has special hierarchical reporting syntax for reporting on parent/child hierarchies.

Hierarchical reporting enables you to sort and select members of parent/child hierarchies without knowing specific generation numbers. A hierarchical reporting request goes through several phases before output is displayed.

Hierarchical Sorting and Member Selection

The first phase selects hierarchy members to display. The hierarchical reporting phrase BY or ON HIERARCHY automatically sorts and formats a hierarchy with appropriate indentations that show the parent/child relationships. If you do not want to see the entire hierarchy, you can use the WHEN phrase to select hierarchy members for display. The expression in this WHEN phrase must reference only hierarchy fields, not dimension properties or measures.

Measures and dimension properties are linked to the leaf nodes of the dimension and, therefore, cannot be used in selecting hierarchy levels for display.

Screening Dimension Data

Once hierarchy members are selected, you can screen the retrieved dimension data by applying WHERE tests to the selected members.

WHERE criteria are applied to the leaf nodes and are processed after the phase of the request that selects hierarchy members. Therefore, dimension properties can be used in WHERE tests.

These tests can also reference hierarchy fields. However, since the selection criteria are always applied to the values at the leaf nodes, they cannot select data based on values that occur at higher levels. For example, in a dimension with Continents, Countries, and Cities, your request will not display any rows if you use WHERE to select at the Country level, but it may if you use it to select at the City level.

WHERE tests can also reference measures if the ENGINE ESSBASE RESTRICTSUM OFF command is in effect.

Screening Based on Aggregated Values

Measures, being summarized values, can be referenced in WHERE TOTAL tests and COMPUTE commands because those commands are processed after the hierarchy selection and aggregation phases of the request. When screening with WHERE TOTAL, the aggregation phase of the report processing is over, so totals on the report are not recalculated to account for the data that is screened out, the rows are just removed. In addition, if you use the RESTRICTSUM OFF setting, you can apply DEFINEs and WHERE tests to measures.

Reference: Prerequisites for Hierarchical Reporting

Hierarchical reporting uses special metadata attributes and reporting syntax. You must:

- ❑ Create a synonym that describes hierarchies as parent/child relationships.

- Use hierarchical reporting syntax in your request to automatically build and format hierarchies in the report output.

For more information on creating synonyms, see *Creating Synonyms* on page 620. For more information on hierarchical reporting, see *Hierarchical Reporting* on page 659.

Representing Hierarchies in a Synonym

Dimensions are organized into sets of hierarchies. For example, in a Time dimension, years, quarters, and months can form a hierarchical or parent/child relationship. This means that the measures for each month are aggregated into values for quarters, and the quarters are aggregated into values for years. Each point in the hierarchy is called a *node*. Nodes at the bottom of the hierarchy (with no children) are called *leaf nodes*.

In a synonym, hierarchies can be described in one of two ways:

- **Level hierarchy.** Each hierarchy level is described using a separate field name. To issue a report request, you must reference the field name for those levels you want to display on the report output.

  When you create a synonym, the synonym contains one field declaration for each level. This declaration also specifies which field is its parent. If the data changes to have an additional level, you must recreate the synonym in order to account for this additional field and parent reference.

- **Parent/child hierarchy.** The hierarchy is described with a set of fields that contain values for properties that describe the position of each member in the hierarchy. For example, there are fields to contain the unique ID, parent, and caption of a member. To issue a report request, you only need to specify the field name of one of the hierarchy fields.

  With a parent/child hierarchy, one set of field names in the synonym describes the hierarchy. A change in the number of levels does not require a change to the parent/child representation of the hierarchy in the synonym.

  Another advantage of parent/child hierarchies is that the adapter can recreate and format any portion of the hierarchy. The request does not have to specify generation numbers.

  Both level and parent/child hierarchies are created for each dimension in the synonym.

Dimension properties apply to all hierarchies in the dimension and are listed in the synonym following all of the hierarchies.

Example: Dimension Declaration

Each dimension begins with a dimension record that defines the dimension and its hierarchies. The dimension itself is generation zero.

Dimension:

```
DIMENSION=Products, CAPTION='Products', $
```

Example: Describing a Level Hierarchy

Each generation of the hierarchy is assigned a field name consisting of the hierarchy name (for example, Manufacturing) with the generation number appended (unless you changed the generation names in the Essbase Client application). Each field declaration also specifies the field name of its parent with the WITHIN attribute. The value stored in this field is the member caption (title).

If a new generation appears in the data, the synonym must be recreated to define this new generation.

The following field describes generation three. Its parent is generation 2:

```
FIELDNAME=WAREHOUSE, ALIAS=Warehouse, USAGE=A11, ACTUAL=A11,
     WITHIN=PLANT,
     PROPERTY=UID,  $
```

Example: Describing a Parent/Child Hierarchy

Several fields are used to define a parent/child hierarchy. Each has a PROPERTY attribute that describes which hierarchy property it represents. The hierarchy field names are formed by appending a suffix to the hierarchy name.

For example, the caption of a hierarchy named Manufacturing2 is stored in a field whose name is MANUFACTURING_CAPTION and whose property attribute is PROPERTY=CAPTION.

The following table describes the hierarchy fields:

Description of Data	PROPERTY=	Field Suffix
Member's Unique ID (unique within the cube)	UID	_MEMBER
Member's Level Number	LEVEL_NUMBER	(Currently not used)
Member's Parent	PARENT_OF	_PARENT
Member's Caption (title on reports)	CAPTION	_CAPTION
Parent's Caption	CAP_PARENT	_PARENTCAP

The following declaration for the Manufacturing2 hierarchy describes the field that contains a member's unique ID (PROPERTY=UID):

```
FIELDNAME=MANUFACTURING_MEMBER, ALIAS=Manufacturing, USAGE=A13,
     ACTUAL=A13,
     WITHIN='*Manufacturing2',
     PROPERTY=UID,  $
```

The following declaration for the Products2 hierarchy defines the field that contains a member's title (PROPERTY=CAPTION):

```
FIELDNAME=MANUFACTURING_CAPTION, USAGE=A17, ACTUAL=A17,
     REFERENCE=MANUFACTURING_MEMBER, PROPERTY=CAPTION,  $
```

Example: Dimension Properties

Following all of a dimension's hierarchies, the dimension properties (called *attributes*) are described. Each of these has PROPERTY=UDA (User Defined Attribute) in the synonym.

For example the following field represents a member's warehouse management property:

```
FIELDNAME=WHSE_MANAGEMENT, ALIAS='Whse Management', USAGE=A15,
   ACTUAL=A15,
   REFERENCE=WAREHOUSE, PROPERTY=UDA,  $
```

Example: Sample Request Using a Level Hierarchy

A report request against a level hierarchy must specify the field name for each generation of the hierarchy required in the report.

For example, the following request displays the sales dollars measure for generations one through three of the Manufacturing hierarchy:

```
TABLE FILE CENTSALE
SUM SALES_DOLLARS
BY MANUFACTURING AS 'LEVEL1'
BY PLANT AS 'LEVEL2'
BY WAREHOUSE AS 'LEVEL3'
ON TABLE COLUMN-TOTAL
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```

The output is:

LEVEL1	LEVEL2	LEVEL3	Sales Dollars
Manufacturing	PLANT 01	Whse 2	129,327,743.98
		Whse 8	130,976,032.31
		Whse 9	132,413,208.98
	Plant 02	Whse 1	125,547,866.13
		Whse 3	139,263,132.99
		Whse 4	129,286,784.49
		Whse 6	210,270,945.82
	Plant 03	Whse 5	131,243,866.46
		Whse 7	122,413,709.11
TOTAL			1,250,743,290.27

In order to get a total for the entire hierarchy, you have to use an ON TABLE COLUMN-TOTAL command in the request or add another SUM command without a BY phrase (and this would add another column to the report output).

Example: Sample Request Using a Parent/Child Hierarchy

A report request against a parent/child hierarchy can use the BY HIERARCHY phrase to report against the entire hierarchy. The output is automatically formatted with appropriate indentations to show the hierarchy generations and relationships.

For example, the following request shows the sales volume measure for three generations of the Manufacturing2 hierarchy:

```
TABLE FILE CENTSALE
SUM SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
SHOW TO DOWN 3
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
END
```

The output is:

MANUFACTURING_CAPTION	Sales Dollars
Manufacturing	1,250,743,290.27
Denver Plant	392,716,985.27
Denver	129,327,743.98
Salem	130,976,032.31
San Diego	132,413,208.98
Kansas City Plant	604,368,729.43
St Louis	125,547,866.13
Dallas	139,263,132.99
Kansas City	210,270,945.82
Seattle	129,286,784.49
Columbia Plant	253,657,575.57
Bangor	131,243,866.46
Columbia	122,413,709.11

The report request does not have to reference specific hierarchy generations. The BY HIERARCHY phrase recreates and formats the hierarchy for display. You can also use a WHEN phrase to select a portion of the hierarchy and a SHOW phrase to specify how many levels above and below the selected portion of the hierarchy you want to display. This display format clearly shows the parent/child relationships between the hierarchy members.

In addition, you can specify whether you want the measure values for each parent to represent aggregates for all of its children (full total) or only those selected for display (visual total).

For more information, see *Hierarchical Reporting* on page 659.

Hierarchical Reporting

When you issue a request against a cube, some of the requirements and features available depend on the type of hierarchy you are reporting against.

With a parent/child hierarchy, you can specify whether the measure values displayed for each parent should show the sum of all of its descendants (full total) or the sum of its displayed descendants (visual total). For level hierarchies, the report always displays full totals, which are the values actually stored in the cube.

For parent/child hierarchies, you can use the BY HIERARCHY phrase to sort and format the hierarchy. You can also limit the portion of the hierarchy selected for display using the WHEN phrase.

When a hierarchical request is processed, the first step is to build the hierarchy and mark which nodes should be included, which should be excluded, and which are needed for context.

The next stage fills the hierarchy with measure values. This stage applies WHERE criteria at the leaf nodes to further qualify the members selected for the report. Dimension properties cannot be used in the initial selection phase of the request, but can be used to screen the selected rows based on dimension data.

Measure values cannot be used to select hierarchy levels for reporting unless the ENGINE ESSBASE RESTRICTSUM OFF setting is in effect. After the hierarchy rows have been selected, screened, and aggregated, WHERE TOTAL tests can limit the rows displayed based on measure values.

It is not currently recommended to use hierarchical reporting with shared members. However, if the ENGINE ESSBASE SUPSHARE ON setting is in effect, a hierarchical report against a hierarchy with shared measures will include any specified shared members, but not members below those shared members.

Syntax: How to Display Parent/Child Hierarchies

The following syntax can be used to generate hierarchical reports when the synonym defines parent/child hierarchies:

```
SUM [FROLL.]measure_field ...
BY hierarchy_field [HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO {BOTTOM|DOWN m}] [byoption [WHEN condition] ...] ]
.
.
.
[WHERE expression_using_dimension_data]
.
.
.
[ON hierarchy_field HIERARCHY [WHEN expression_using_hierarchy_fields;]
[SHOW [TOP|UP n] [TO BOTTOM|DOWN m] [byoption [WHEN condition] ...]]
```

where:

FROLL

Specifies a full roll-up of the measure. With a full roll-up, the value displayed is the value found in the cube. This value may not reflect the sum of its displayed descendants if some descendants are eliminated from the output based on the WHEN and SHOW options. When FROLL is not specified, the value displayed is a visual total, which means it is the total of the values for its displayed descendants.

Note: If a request uses WHERE criteria to screen out some data, FROLL will not display the value found in the cube. It will display the roll-up of the selected data.

measure_field

Is the field name of a measure.

BY *hierarchy_field* HIERARCHY

Identifies the hierarchy used for sorting. The field must be a hierarchy field.

ON *hierarchy_field* HIERARCHY

Identifies the hierarchy used for sorting. The field must be a hierarchy field. The request must include either a BY phrase or a BY HIERARCHY phrase for this field name.

WHEN *expression_using_hierarchy_fields*;

Selects hierarchy members. The WHEN phrase must immediately follow the word HIERARCHY to distinguish it from a WHEN phrase associated with a BY option (such as SUBFOOT). Any expression using only hierarchy fields is supported. The WHEN phrase can be on the BY HIERARCHY command or the ON HIERARCHY command, but not both.

SHOW

Specifies which levels to show on the report output relative to the levels selected by the WHEN phrase. If there is no WHEN phrase, the SHOW option is applied to the root node of the hierarchy. The SHOW option can be specified on the BY HIERARCHY phrase or the ON HIERARCHY phrase, but not both.

n

Is the number of ascendants above the set of selected members that will have measure values. All ascendants appear on the report to show the hierarchical context of the selected members. However, ascendants that are not included in the SHOW phrase appear on the report with missing data symbols in the report columns that display measures. The default for *n* is 0.

TOP

Specifies that ascendant levels to the root node of the hierarchy will be populated with measure values.

TO

Is required when specifying a SHOW option for descendant levels.

BOTTOM

Specifies all descendants to the leaf nodes of the hierarchy will be populated with measure values. This is the default value.

m

Is the number of descendants of each selected level that will display. The default for *m* is BOTTOM, which displays all descendants.

byoption

Is one of the following sort-based options: PAGE-BREAK, REPAGE, RECAP, RECOMPUTE, SKIP-LINE, SUBFOOT, SUBHEAD, SUBTOTAL, SUB-TOTAL, SUMMARIZE, UNDER-LINE. If you specify SUBHEAD or SUBFOOT, you must place the WHEN phrase on the line following the heading or footing text.

condition

Is a logical expression.

expression_using_dimension_data

Screens the rows selected in the BY/ON HIERARCHY and WHEN phrases based on dimension data. The expression can use dimension properties, measures (with RETRICTSUM OFF), and hierarchy fields; however, the selection criteria are always applied to the values at the leaf nodes. Therefore, you cannot use WHERE to select rows based on hierarchy field values that occur at higher levels. For example, in a dimension with Continents, Countries, and Cities, your request will not display any rows if you use WHERE to select a Country name, but it may if you use it to select a City name.

The following examples illustrate hierarchical reporting using the BY HIERARCHY phrase.

Example: Reporting on a Whole Hierarchy

The following request produces visual totals (SALES_DOLLARS) and full totals (FROLL.SALES_DOLLARS). The BY HIERARCHY phrase specifies hierarchical reporting. There is no WHEN phrase to limit the portion of the hierarchy displayed. Also note that the full roll-up is displayed with the prefix FSUM added to the field name. The full total is the same as the visual total for a report on the entire hierarchy:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Reporting on a Whole Hierarchy"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The top portion of the hierarchy is:

Reporting on a Whole Hierarchy

AMD DESKTOP	9,616,766.82	9,616,766.82

Example: Selecting a Hierarchy Member

The following request produces a visual total and full total for the Products2 hierarchy of the Products dimension, but limits the members selected for display with the WHEN phrase. Note that the hierarchy member selected is displayed in its context (all ancestors to the root of the hierarchy). However, the ancestors are not requested in the report and are, therefore, displayed with missing data symbols. All descendants of the selected members appear in the report output because the default SHOW option for descendants is BOTTOM:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'LAPTOP';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Hierarchy Member"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting a Hierarchy Member

P4 NOTEBOOK COMPUTER 8KG	14,211,416.80	14,211,416.80

Example: Selecting a Member and Adding a Parent

In the following request, the SHOW option UP 1 TO DOWN 0 added to the WHEN phrase adds the parent (LAP-DESKTOP) of the selected member (LAPTOP). This parent now contains values for the measures rather than missing data symbols. However, the full total column for the parent contains the sum of all of its descendants, not just the selected LAPTOP member, while the visual total shows the total only for the LAPTOP member:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'LAPTOP';
SHOW UP 1 TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding a Parent"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting a Member and Adding a Parent

PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Products	.	.
COMPUTER	.	.
COMPUTERS	.	.
LAP-DESKTOP	111,469,451.84	161,978,073.61
LAPTOP	111,469,451.84	111,469,451.84

Example: **Selecting a Member and Adding Children**

In the following request, the SHOW option UP 0 TO DOWN 1 added to the WHEN phrase adds the children of the selected member (LAPTOP). Because no children of the selected member are excluded, and no higher level members are in the SHOW set, the full and visual totals are the same:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'LAPTOP';
SHOW UP 0 TO DOWN 1
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding Children"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting a Member and Adding Children

PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Products	.	.

P4 LAPTOP	21,445,792.29	21,445,792.29
NOTEBOOK P-4=2.4/30GB/	24,296,762.60	24,296,762.60
LAPTOP COMPUTER 1.2	20,413,907.75	20,413,907.75
P4 NOTEBOOK COMPUTER 8KG	14,211,416.80	14,211,416.80

Example: Selecting a Member and Showing All Ascendants

In the following request, the SHOW option TOP TO DOWN 0 added to the WHEN phrase adds all ascendants but no descendants of the selected member (LAPTOP). These parents now contain values for the measures rather than missing data symbols. However, the full total column for the ascendants contains the sum of all of their descendants, not just the specified LAPTOP member, while the visual total shows the total for only the LAPTOP member:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'LAPTOP';
SHOW TOP TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting a Member and Adding All Ascendants

PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Products	111,469,451.84	1,250,743,290.27
COMPUTER	111,469,451.84	65,905,435.61
COMPUTERS	111,469,451.84	65,905,435.61

LAPTOP	111,469,451.84	111,469,451.84

Example: Selecting a Member and Showing All Ascendants and Descendants

In the following request, the SHOW option TOP added to the WHEN phrase adds all ascendants and descendants (since TO BOTTOM is the default) of the selected member (LAPTOP). These parents are now in the SHOW set and contain values for the measures rather than missing data symbols. However, the full total column for the ascendants contains the sums of all of their descendants, not just the specified LAPTOP member, while the visual total shows the total for only the LAPTOP member:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'LAPTOP';
SHOW TOP
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting a Member and Adding All Ascendants and Descendants"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting a Member and Adding All Ascendants and Descendants

PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Products	111,469,451.84	1,250,743,290.27

P4 LAPTOP	21,445,792.29	21,445,792.29
NOTEBOOK P-4=2.4/30GB/	24,296,762.60	24,296,762.60
LAPTOP COMPUTER 1.2	20,413,907.75	20,413,907.75
P4 NOTEBOOK COMPUTER 8KG	14,211,416.80	14,211,416.80

Example: Selecting Members for Display and Screening on Member Values

You use the WHEN phrase to select hierarchy members to display on the report. Each of the selected members is displayed in its context. The ascendants of selected members display missing data symbols. When a request is processed, the first step is to build the hierarchy and mark which nodes should be included, which should be excluded, and which are needed for context but should display missing data symbols according to the WHEN phrase.

The next stage fills the hierarchy with measure values. This stage applies WHERE criteria (which must select on the lowest level of the hierarchy or the report will be empty).

If a WHERE is specified without a WHEN, no nodes are marked as excluded, so no nodes display missing values.

The following request shows the Manufacturing2 hierarchy:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting Hierarchy Members"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting Hierarchy Members

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	1,250,743,290.27	1,250,743,290.27
Denver Plant	392,716,985.27	392,716,985.27
Denver	129,327,743.98	129,327,743.98
Salem	130,976,032.31	130,976,032.31
San Diego	132,413,208.98	132,413,208.98
Kansas City Plant	604,368,729.43	604,368,729.43
St Louis	125,547,866.13	125,547,866.13
Dallas	139,263,132.99	139,263,132.99
Kansas City	210,270,945.82	210,270,945.82
Seattle	129,286,784.49	129,286,784.49
Columbia Plant	253,657,575.57	253,657,575.57
Bangor	131,243,866.46	131,243,866.46
Columbia	122,413,709.11	122,413,709.11

The following request selects the portion of the hierarchy whose members contain the value *Plant* or *City*. It then screens on the dimension attribute WHSE_MANAGEMENT equal to *Leased* or *Owned*. This WHERE screening condition does not affect the portion of the hierarchy that was selected by WHEN, but it does not display or include in the totals those rows that had no data meeting the WHERE condition:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'City' OR 'Plant';
WHERE WHSE_MANAGEMENT EQ 'Leased' OR 'Owned'
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Selecting Members and Screening Data Values"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Selecting Members and Screening Data Values

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	.	.
Denver Plant	129,327,743.98	.
Denver	129,327,743.98	129,327,743.98
Kansas City Plant	394,097,783.61	.
St Louis	125,547,866.13	125,547,866.13
Dallas	139,263,132.99	139,263,132.99
Seattle	129,286,784.49	129,286,784.49
Columbia Plant	131,243,866.46	.
Bangor	131,243,866.46	131,243,866.46

Note that the full total is a value taken directly from the data source. It must pass both the WHEN and WHERE conditions in order to be retrieved and, therefore, is represented by a missing value in some rows. The visual total is calculated starting from the leaf nodes, so it is present for higher levels even if a higher level record does not pass the WHERE condition.

Example: Comparing Member Selection With Data Screening

The following request selects hierarchy members whose captions contains the value *Plant* and, from those selected members, screens values at the lowest level of the hierarchy for captions containing *City*:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'Plant';
WHERE MANUFACTURING_CAPTION CONTAINS 'City'
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Comparing Member Selection With Data Screening"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Comparing Member Selection With Data Screening

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	.	.
Kansas City Plant	210,270,945.82	210,270,945.82
Kansas City	210,270,945.82	210,270,945.82

Note that the WHERE condition removes all leaf nodes except *Kansas City* from the hierarchy display and from the totals.

Example: Reporting on Shared Members

The following request sets SUPSHARE ON and reports on the Customers2 hierarchy, which has shared members. The WHERE TOTAL test screens on the measure SALES_DOLLARS to remove rows with zero sales dollars. No members below the shared members display on the report output:

```
ENGINE ESSBASE SET SUPSHARE ON
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY CUSTOMERS_CAPTION HIERARCHY
WHEN CUSTOMERS_CAPTION CONTAINS 'Rep';
SHOW TO BOTTOM
WHERE TOTAL SALES_DOLLARS NE 0;
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Reporting on Shared Members"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Reporting on Shared Members

CUSTOMERS_CAPTION	Sales Dollars	FSUM Sales Dollars
Sales Representatives	707,840,214.13	1,250,743,290.27
Adam Scott	65,632,990.59	65,632,990.59
Andrew Lowell	.	148,809,230.28
Barbara Shas	.	244,107,115.97
Dan Joshes	958,086.61	958,086.61
Eric Craig	206,543,715.76	206,543,715.76
Justin Miller	.	63,672,254.93
Rich Green	1,966,189.11	1,966,189.11
Robyn Gold	421,507,869.83	421,507,869.83
Steven Davis	.	86,314,474.96
Tim Karis	11,231,362.23	11,231,362.23

Example: Using SHOW Without WHEN

The following request does not contain a WHEN phrase, so the SHOW option DOWN TO 0 applies to the root node (as if there had been a WHEN phrase that selected only the root node). Therefore, the root level is the only one shown on the report output:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
SHOW TO DOWN 0
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"SHOW Without WHEN"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

SHOW Without WHEN

PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Products	1,594,324,089.21	1,594,324,089.21

Example: Using SKIP-LINE

The following request adds the BY option SKIP-LINE to the BY HIERARCHY phrase:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'City';
SHOW UP 1 TO DOWN 1 SKIP-LINE
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using SKIP-LINE"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Using SKIP-LINE

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	604,368,729.43	1,250,743,290.27
Kansas City Plant	604,368,729.43	604,368,729.43
St Louis	125,547,866.13	125,547,866.13
Dallas	139,263,132.99	139,263,132.99
Kansas City	210,270,945.82	210,270,945.82
Seattle	129,286,784.49	129,286,784.49

Example: Using Conditional Sort Options

The following request has a BY HIERARCHY command with a WHEN phrase to select members as well as a WHEN phrase to control the UNDER-LINE option.

The SUBFOOT option is in an ON phrase that references the same hierarchy field (all of the BY options could have been on the BY HIERARCHY phrase).

Each BY option has its own WHEN phrase. The WHEN phrase for the SUBFOOT option uses a measure field in its expression. The WHEN phrase for the UNDER-LINE option uses a hierarchy field in its expression. Attribute fields are not supported in WHEN phrases. They can only be used in IF or WHERE tests.

In this example, one BY option is activated WHEN the MANUFACTURING_CAPTION contains *City*. The other BY option creates a subfoot WHEN SALES_DOLLARS is greater than or equal to $600,000,000:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'Plant' ;
SHOW TOP UNDER-LINE WHEN MANUFACTURING_CAPTION CONTAINS 'City';
ON MANUFACTURING_CAPTION SUBFOOT
" "
"The Sum is large"
" "
WHEN SALES_DOLLARS GE 600000000;
ON TABLE SUBHEAD
"Using BY Options With WHEN on a Measure and a Hierarchy Field"
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Using BY Options With WHEN on a Measure and a Hierarchy Field

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	1,250,743,290.27	1,250,743,290.27
The Sum is large		
Denver Plant	392,716,985.27	392,716,985.27
Denver	129,327,743.98	129,327,743.98
Salem	130,976,032.31	130,976,032.31
San Diego	132,413,208.98	132,413,208.98
Kansas City Plant	604,368,729.43	604,368,729.43
The Sum is large		
St Louis	125,547,866.13	125,547,866.13
Dallas	139,263,132.99	139,263,132.99
Kansas City	210,270,945.82	210,270,945.82
Seattle	129,286,784.49	129,286,784.49
Columbia Plant	253,657,575.57	253,657,575.57
Bangor	131,243,866.46	131,243,866.46
Columbia	122,413,709.11	122,413,709.11

Example: Using Two BY HIERARCHY Phrases

The following request has a BY HIERARCHY phrase for the Products2 hierarchy and a second BY HIERARCHY phrase for the Manufacturing2 hierarchy (which is from a different dimension, as required). All selected members for the Manufacturing2 hierarchy are repeated for each selected member of the Products2 hierarchy. The WHERE TOTAL phrase omits rows in which SALES_DOLLARS is less than $1,000,000:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'PDA';
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'City';
WHERE TOTAL SALES_DOLLARS GE 1000000;
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using Two BY HIERARCHY Phrases"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Using Two BY HIERARCHY Phrases

PRODUCTS_CAPTION	MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
PDA	Kansas City Plant	4,378,416.60	4,378,416.60
	Dallas	1,405,923.22	1,405,923.22
	Seattle	1,084,629.34	1,084,629.34
AMD MICRO	Kansas City Plant	4,378,416.60	4,378,416.60
	Dallas	1,405,923.22	1,405,923.22
	Seattle	1,084,629.34	1,084,629.34
AMD DESKTOP	Kansas City Plant	4,378,416.60	4,378,416.60
	Dallas	1,405,923.22	1,405,923.22
	Seattle	1,084,629.34	1,084,629.34

Example: Using BY HIERARCHY and BY Phrases

The following request has a BY phrase for the Manufacturing2 hierarchy and a BY HIERARCHY phrase for the Products2 hierarchy. All selected members for the Products2 hierarchy are repeated for each selected member of the Manufacturing2 hierarchy (which is not displayed with hierarchical indentations when referenced in a BY phrase). A BY on a unique field is required. Therefore, there is one BY on a unique field with the NOPRINT option and another BY on the caption field:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_MEMBER NOPRINT
BY MANUFACTURING_CAPTION
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'PDA';
WHERE MANUFACTURING_CAPTION CONTAINS 'Plant';
WHERE TOTAL SALES_DOLLARS GE 1000000;
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using BY HIERARCHY and BY Phrases"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Using BY HIERARCHY and BY Phrases

MANUFACTURING_CAPTION	PRODUCTS_CAPTION	Sales Dollars	FSUM Sales Dollars
Denver Plant	PDA	3,209,788.86	3,209,788.86
	AMD MICRO	3,209,788.86	3,209,788.86
	AMD DESKTOP	3,209,788.86	3,209,788.86
Kansas City Plant	PDA	4,378,416.60	4,378,416.60
	AMD MICRO	4,378,416.60	4,378,416.60
	AMD DESKTOP	4,378,416.60	4,378,416.60
Columbia Plant	PDA	2,028,561.36	2,028,561.36
	AMD MICRO	2,028,561.36	2,028,561.36
	AMD DESKTOP	2,028,561.36	2,028,561.36

Example: Using ON HIERARCHY Without BY HIERARCHY

The following request has a BY phrase and an ON HIERARCHY phrase for the Manufacturing2 hierarchy. All hierarchy options and BY options are supported on the ON HIERARCHY phrase. This request also has a WHERE clause that selects rows based on the value of a hierarchy field (MANUFACTURING_CAPTION). The WHERE test selects rows based on values at the leaf nodes:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS FROLL.SALES_DOLLARS
BY MANUFACTURING_CAPTION
ON MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'Plant';
WHERE MANUFACTURING_CAPTION CONTAINS 'City';
ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using ON HIERARCHY"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The output is:

Using ON HIERARCHY

MANUFACTURING_CAPTION	Sales Dollars	FSUM Sales Dollars
Manufacturing	.	.
Kansas City Plant	210,270,945.82	210,270,945.82
Kansas City	210,270,945.82	210,270,945.82

Reference: **Hierarchical Reports With Multiple Display Commands**

In a request with more than one display command, each command must repeat all of the sort phrases from the previous command in the same order after which additional sort phrases can be added. In a hierarchical reporting request, the following rules must be followed:

- All display commands must be summation commands. PRINT is not supported in a hierarchical reporting request.
- Both BY and BY HIERARCHY sort phrases can be used. As with a non-hierarchical request, all of the sort phrases must be repeated in the same order with a subsequent display command.
- Only one WHEN and one SHOW phrase can be specified for each hierarchy referenced in the request. These phrases can be specified at any level of the request, but they will apply to every display command in the request.

Example: Using Multiple Display Commands in a Hierarchical Report

The following request has two WRITE commands. The first WRITE command has a BY HIERARCHY sort phrase for the Products2 hierarchy and a BY HIERARCHY phrase for the Manufacturing2 hierarchy. The second WRITE command repeats these phrases and adds a BY phrase for the Customers2 hierarchy:

```
TABLE FILE CENTSALE
WRITE SALES_DOLLARS
BY PRODUCTS_CAPTION HIERARCHY
WHEN PRODUCTS_CAPTION EQ 'PDA';
SHOW TO DOWN 0
BY MANUFACTURING_CAPTION HIERARCHY
WHEN MANUFACTURING_CAPTION CONTAINS 'Plant';
SHOW TO DOWN 0
WRITE SALES_DOLLARS UNITS
BY PRODUCTS_CAPTION HIERARCHY
BY MANUFACTURING_CAPTION HIERARCHY
BY CUSTOMERS_CAPTION
WHERE CUSTOMERS_MEMBER LIKE '01%'
WHERE TOTAL SALES_DOLLARS NE 0

ON TABLE SET PAGE NOPAGE
ON TABLE SUBHEAD
"Using Multiple Display Commands"
ON TABLE SET STYLE *
TYPE=REPORT, SIZE=8,$
TYPE=REPORT, GRID=OFF, WRAP=OFF, $
TYPE=TABHEADING, SIZE=10, COLOR=RED, JUSTIFY=CENTER, $
END
```

The BY HIERARCHY phrase for the Products2 hierarchy has a WHEN phrase that selects members whose caption is *PDA*. The SHOW option (TO DOWN 2) displays two levels of descendants below the PDA level.

For the Manufacturing2 hierarchy, the selected members have the characters *Plant* in their captions. The SHOW option displays no descendants on the report output. All selected members of the Manufacturing2 hierarchy display for each selected member of the Products2 hierarchy.

The WHERE TOTAL test removes all rows with zero SALES_DOLLARS from the report output. The WHERE test selects customers whose member values begin with 01.

The output is:

Using Multiple Display Commands

PRODUCTS_CAPTION	MANUFACTURING_CAPTION	Sales Dollars	CUSTOMERS_CAPTION	Sales Dollars	Units
PDA	Denver Plant	11,549.78	.	11,549.78	11.00
	Kansas City Plant	9,449.82	.	9,449.82	9.00
	Columbia Plant	3,149.94	.	3,149.94	3.00
AMD MICRO	Denver Plant	11,549.78	.	11,549.78	11.00
	Kansas City Plant	9,449.82	.	9,449.82	9.00
	Columbia Plant	3,149.94	.	3,149.94	3.00
AMD DESKTOP	Denver Plant	11,549.78	ACE`S, INC.	9,449.82	9.00
			ANCONA BROTHERS	2,099.96	2.00
	Kansas City Plant	9,449.82	VSA INC	9,449.82	9.00
	Columbia Plant	3,149.94	SUNSET DISTRIBUTING	3,149.94	3.00

Columnar Reporting

If you run a standard TABLE or FML report against a cube, you are running what is known as a columnar report. A columnar report flattens out the multi-dimensional structure of a cube to show information from one angle.

To create a valid columnar report, you must understand the data structure of the cube and the logic and assumptions that the adapter uses when retrieving values from a cube.

The adapter has built-in logic that enables it to determine the rows and cells to extract from rollups in order to deliver reports. TABLE uses the lowest level BY phrase for each dimension to determine at which rollup to locate the lookup for aggregations. It then rolls the result up from there, performing aggregations on the data as needed to ensure the consistency of the results.

If you do not specify a BY field in your TABLE request, you may receive invalid data or a message. This happens because without a BY field to determine the level of rollup at which to perform the data lookup, TABLE does not know where to source the result. At least one BY phrase (perhaps with the NOPRINT option) must be on a field with unique values.

Reference: Reporting on Measures

The Essbase Server does not support the use of SUM or PRINT on an Measure without reference to another dimension in the request.

For example, since this request refers only to measure,

```
TABLE FILE BASIC
PRINT DATA_VALUE
END
```

the following message displays:

```
(FOC43244) No active dimension found in the request.
```

Reference: Columnar Reporting on a Parent/Child View

You cannot reference PARENT or PARENTCAP from the parent/child view without referencing MEMBER or CAPTION, unless you are using it as a filter.

Example: Referencing MEMBER and CAPTION Attributes

The following request is incorrect since it does not reference MEMBER or CAPTION.

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY PRODUCT_PARENT
WHERE PRODUCT_PARENT EQ 'Visual'
END
```

The following message displays:

```
(FOC43248) Can't reference PRODUCT's PARENT,PARENTCAP without MEMBER or
CAPTION.
```

The correct request is:

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY PRODUCT_PARENT
BY PRODUCT_MEMBER
WHERE PRODUCT_PARENT EQ 'Visual'
END
```

The output is:

```
PRODUCT_PARENT    PRODUCT_MEMBER        DATA_VALUE
--------------    --------------        ----------
Visual            Camera                 20,971.00
                  Television             27,877.00
                  VCR                    49,206.00
```

You cannot reference fields from the Generation view (GEN1_PRODUCT or GEN2_PRODUCT) and from the parent/child view (PRODUCT_MEMBER or PRODUCT_CAPTION) in one request if the fields from these different views are from the same dimension.

For example, in the following request

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY PRODUCT_MEMBER
BY FAMILY
WHERE PRODUCT_MEMBER EQ 'Visual'
END
```

FAMILY is a member of the Product dimension and part of the Generation view so the following message is generated:

```
(FOC43247) Can't reference fields from Product2 and Product at the same
time.
```

The correct request is:

```
TABLE FILE BASIC
PRINT DATA_VALUE
BY PRODUCT_MEMBER
BY SCENARIO
WHERE PRODUCT_MEMBER EQ 'Visual'
END
```

The output is:

```
PRODUCT_MEMBER  SCENARIO     DATA_VALUE
--------------  --------     ----------
Camera          Scenario      20,971.00
Television      Scenario      27,877.00
VCR             Scenario      49,206.00
```

Syntax:

How to Collapse PRINT With ACROSS

The PRINT command generates a report that has a single line for each record retrieved from the data source after screening out those that fail IF or WHERE tests. When PRINT is used in conjunction with an ACROSS phrase, many of the generated columns may be empty. Those columns display the missing data symbol.

To avoid printing such a sparse report, you can use the SET ACROSSPRT command to compress the lines in the report. The number of lines is reduced within each sort group by swapping non-missing values from lower lines with missing values from higher lines, and then eliminating any lines whose columns all have missing values.

Because data may be moved to different report lines, row-based calculations such as ROW-TOTAL and ACROSS-TOTAL in a compressed report are different from those in a non-compressed report. Column calculations are not affected by compressing the report lines.

The syntax is

```
SET ACROSSPRT = {NORMAL|COMPRESS}
```

```
ON TABLE SET ACROSSPRT {NORMAL|COMPRESS}
```

where:

NORMAL

Does not compress report lines.

COMPRESS

Compresses report lines by promoting data values up within a sort group.

Example: Compressing Report Output

The following request against the Adventure Works cube prints average sales by country across calendar year:

```
TABLE FILE ADVENTURE_WORKS
PRINT INTERNET_AVERAGE_SALES_AMOUNT/D8.1 AS 'Average Sales'
BY COUNTRY51
ACROSS CALENDAR_YEAR4
WHERE COUNTRY51 EQ 'France' OR 'Germany' OR 'United Kingdom'
ON TABLE SET ACROSSPRT NORMAL
ON TABLE SET PAGE-NUM OFF
END
```

Each line of the report output represents one value of average sales for one year, so at most one column on each line has a value when ACROSSPRT is set to NORMAL (the default). The output is:

	Calendar Year			
	CY 2001	CY 2002	CY 2003	CY 2004
Country	Average Sales	Average Sales	Average Sales	Average Sales
France	3,084.2	.	.	.
	.	2,232.1	.	.
	.	.	1,000.7	.
	.	.	.	802.7
Germany	3,133.9	.	.	.
	.	2,275.9	.	.
	.	.	1,081.3	.
	.	.	.	909.6
United Kingdom	3,020.0	.	.	.
	.	2,261.5	.	.
	.	.	1,047.5	.
	.	.	.	856.5

Running the same request with ACROSSPRT=COMPRESS moves data values from lower lines to higher lines within the same BY group and eliminates lines that have all missing values:

```
TABLE FILE ADVENTURE_WORKS
PRINT INTERNET_AVERAGE_SALES_AMOUNT/D8.1 AS 'Average Sales'
BY COUNTRY51
ACROSS CALENDAR_YEAR4
WHERE COUNTRY51 EQ 'France' OR 'Germany' OR 'United Kingdom'
ON TABLE SET ACROSSPRT COMPRESS
ON TABLE SET PAGE-NUM OFF
END
```

The output is:

	Calendar Year			
	CY 2001	CY 2002	CY 2003	CY 2004
Country	Average Sales	Average Sales	Average Sales	Average Sales
France	3,084.2	2,232.1	1,000.7	802.7
Germany	3,133.9	2,275.9	1,081.3	909.6
United Kingdom	3,020.0	2,261.5	1,047.5	856.5

Full and Partial Aggregation

Cube requests are requests that reference at least one measure and possibly more than one hierarchy. Attributes may also be referenced.

For cube requests, the adapter reads cells with fully or partially aggregated data from the cube and applies certain restrictions on the contents of the TABLE request to ensure consistency of reports.

There are two modes in which cube requests are processed: *Full Aggregation* and *Partial Aggregation*.

- In full aggregation mode, the adapter retrieves aggregated values from the cube exactly as they will be displayed on the report.
- In partial aggregation mode the Adapter retrieves partially aggregated data which is then further aggregated by WebFOCUS.

Full aggregation mode is more efficient because no aggregation is needed beyond what is already stored in the cube.

Reference: Support for Full Aggregation Mode

The following table describes support for full aggregation mode:

Command	Dimension Properties	Measures	Attributes
WRITE/ SUM/ADD	Supported, converted to FST.	Supported, converted to an operation that matches the measure aggregator.	Not supported.

Command	Dimension Properties	Measures	Attributes
COMPUTE	Supported.	Supported.	Not supported.
PRINT	Supported.	Supported for compatibility. Not supported with BY HIERARCHY.	Not supported.
WHERE TOTAL	Supported	Supported	Not supported.
WHERE	Supported	Supported with RESTRICTSUM.	Required for attributes. Must provide required restriction for its variable selection type. Restricted to a group of fields that represent a single attribute.
WHEN	Supported	Not supported.	Not supported.
DEFINE	Supported	Supported with RESTRICTSUM.	Not supported.
BY	Supported. Requires BY on a unique field of a parent/ child hierarchy (except when referenced only in a WHERE). BY HIERARCHY adds BY internally.	Not supported.	Not supported.
BY HIERARCHY	Supported.	Not supported.	Not supported.

Command	Dimension Properties	Measures	Attributes
ON HIERARCHY	Supported. Requires a corresponding BY or BY HIERARCHY phrase.	Not supported.	Not supported.

Reference: Support for Partial Aggregation Mode

In partial aggregation mode, there are additional restrictions on the use of measures. Note that in requests with multiple display commands, the partial aggregation restrictions apply to all display commands except for the ones associated with the lowest BY phrase:

- Additive aggregators (those that can be further aggregated from partial totals such as SUM., CNT., MAX., and MIN.) are supported as long as they match the measure aggregator.
- Non-additive aggregators (such as AVE.) are not supported.

The following factors turn on partial aggregation mode:

- Multiple display commands.
- Parent/Child hierarchies: Visual totals or Full totals with a WHERE on the hierarchy.
- Level hierarchies: not all levels of a hierarchy that are referenced in the request have BY phrases.
- All hierarchies: the hierarchy is referenced only in a WHERE clause that selects more than one member.

Reporting Rules

The reporting rules and features vary depending on the types of hierarchies defined in the synonym. These factors are summarized in the following sections.

Reference: Display Command and Prefix Operator Support

When BY HIERARCHY is not used in the request, the display command can be PRINT, even for aggregated data. It is internally converted to the appropriate command.

Note: To emphasize that the summary values are already in the cube and do not necessarily require any additional aggregation, the examples use the WRITE command, which is a synonym for SUM.

The measure operation is also automatically supplied internally; you do not have to specify a prefix operator in the request. However, if you do specify a prefix operator, it should match the measure aggregator.

Prefix operators in a request have an effect in two situations. You can use the FROLL prefix operator to specify a full total in a BY HIERARCHY request. Also, requests with multiple display commands (and sort groups) use the prefix operator to determine the sort order of the high level sort groups.

Reference: Reporting Rules for All Hierarchies

BY. Lexicographic sort is available on any of the member properties as well as expressions (DEFINEs) based on properties, but the request must include a sort (possibly with the NOPRINT option) on a property that is guaranteed to uniquely identify a hierarchy member, either PROPERTY=UID or PROPERTY=NAME. BY HIERARCHY automatically adds a BY one of these properties. In a report referencing a level hierarchy, the request must specify one.

Hierarchies. Only one hierarchy from the same dimension can be represented on the report.

Measures. Filtering on totals is done using WHERE or WHERE TOTAL tests. Calculations on totals are done using DEFINE or COMPUTE (RESTRICTSUM ON).

Screening. Screening on member properties is available with and without sorting.

Joins. The adapter does not support direct JOINs from or to a cube. Therefore, SQL joins using a WHERE clause are not supported. To achieve a joined request, use the WebFOCUS MATCH FILE command or create a HOLD file and use the HOLD file in the request.

Reference: Reporting Rules for Parent/Child Hierarchies

BY HIERARCHY. Requires the command SUM, WRITE, or ADD. PRINT is not supported.

Hierarchical Context. The set of members selected for the report using a WHEN test is augmented so that every member of the hierarchy is shown within its hierarchical context. The displayed subtree of hierarchy members is a contiguous tree whose root is the root of the whole hierarchy. The added context members are shown without totals.

Report Compression. By default, hierarchy members with no fact data do not participate in the report. Hierarchy members for which no data passes screening do not participate in the report. In a multi-hierarchy report, the inner hierarchies are not shown for those members of outer hierarchies that appear on the report output only to show the context of selected members.

Full and visual totals. Visual totals for each node are composed from the totals of its hierarchical children shown on the same report. These are compatible with the totals shown for the same members in a multi-verb level-wise report. Visual totals are the default. The report can specify full totals by specifying the prefix operator FROLL on a measure field. Full totals are accumulated for each displayed hierarchy member individually. These are compatible with the totals shown for the same members in a non-hierarchical report on a parent-child hierarchy.

General Tips for Reporting

When creating a report request:

- PRINT and SUM can be used interchangeably when using level hierarchies.
- To maximize reporting efficiency, always sort in the same direction as the hierarchy for the cube. For example, if the hierarchy for a dimension is

  Country > State_Province > City

  sorting by City first, then State_Province results in an inefficient request. Also, because of the hierarchical structure of OLAP, you retrieve only one BY field for each SUM or PRINT field in the report.

Chapter 23

Using the Adapter for EXASol

The Adapter for EXASol allows applications to access EXASolution data sources. The adapter converts data or application requests into native EXASol SQL statements and returns optimized answer sets to the requesting program.

In this chapter:

Introducing the Adapter for EXASol

The Adapter for EXASol is ODBC based. It utilizes EXASolution ODBC driver version 5.0.15 or higher, that can be installed on Windows and Linux.

Preparing the EXASol ODBC Environment

On Windows, the EXASol ODBC environment is set up during the installation of the EXASolution ODBC driver. No additional setup steps are required.

On Linux, after the EXASolution ODBC driver is installed, make sure that path to the directory where EXASol driver installed is included in LD_LIBRARY_PATH (or in IBI_LIBPATH if the server is running with security on).

For example:

```
export IBI_LIBPATH=/rdbms/exasol/EXASolution_ODBC-5.0.15/lib/x86_64
```

Configuring the Adapter for EXASol

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the EXASol Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. Right-click *EXASol* and click *Configure*.
4. Select *edasprof* from the drop-down menu to add this connection for all users, or select a user profile.
5. Click *Test*. You should see a sample list of objects stored in the EXASol data source you are accessing.
6. Click *Configure*.

Reference: EXASol Adapter Configuration Settings

The Adapter for EXASol is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

System

Is the name of the machine where the EXASol in-memory database is running. The basic syntax is *host*:*port*

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Additional connection string keywords (optional)
Can be used to add options to the connection string, for example, EXASCHEMA.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Reference: Configuring an Auxiliary Connection for Extended Bulk Load

Using Extended Bulk Load with the EXASol adapter requires that intermediate data files are transferred to a server where the EXASol sever can access them.

For this adapter, you must enable the Flat File adapter and create a connection using FTP or SFTP to the server. From the DMC or Web Console, perform the following steps:

1. Expand the *Adapters* folder or click the *Adapters* tab.
2. Right-click *Flat File* and click *Add Connection*.
3. In the Connection Name box, type the name of the connection for your EXASol server. The connection names must match.
4. From the Protocol drop-down menu, select *FTP* or *SFTP*.
5. In the Host Name box, type the name of the host for your server.

   Note: For EXASol it should not be the system where it is running, rather it should be some other system that it can access using FTP.
6. In the Initial Directory box, type the name of a directory that you have write access to, such as your home directory.

7. In the User and Password boxes, type your user ID and password.
8. Click *Test*.

   The following message should appear: *User has read access to the FTP server*.
9. Click *OK*.
10. Click *Configure*.
11. Click *Close*.

Creating Synonyms With EXASol

Synonyms define unique names, or aliases, for each EXASol table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given EXASol table.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Using Direct Pass-through With EXASol

Direct Pass-through commands, such as SHOW TABLES and DESCRIBE tablename, do not display any results.

This can be avoided by adding a comment:

```
ENGINE SQLEXA
/*QUERY*/ SHOW TABLES ;
END
```

Chapter 24

Using the Adapter for Excel

The Adapter for Excel allows applications to access Excel data sources. The adapter returns answer sets to the requesting application.

In this chapter:

Configuring the Adapter for Excel

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to the Excel database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one Excel database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Excel Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Excel

The Excel adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

The data source name (DSN). There is no default data source name. You must enter a value.

This must be the name of an ODBC data source configured for the "Microsoft Excel Driver." If a File DSN is used, this must be the name of the file (for example, samplefdsn.dsn).

Security

There are two methods by which a user can be authenticated when connecting to a data source:

- **Explicit.** Not applicable for Excel. Reserved for future use.
- **Trusted.** The adapter connects to the EXCEL data source as a Windows login using the credentials of the operating system user imitated by the server data access agent (Default).

User

Not applicable for Excel. Reserved for future use.

Password

Not applicable for Excel. Reserved for future use.

File DSN parameters (optional)

Is the path to the ODBC File DSN that is defined on your Windows machine or network.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

For User/System DSN:

```
ENGINE SQLEXCEL SET CONNECTION_ATTRIBUTES connection DSN_name/,
```

For File DSN:

```
ENGINE [SQLEXCEL] SET CONNECTION_ATTRIBUTES connection
 FileDSN_name/,:'filedsn=FileDSN_path;',
```

where:

`SQLEXCEL`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and DSN_*name*.

`DSN_name`

Is the Excel Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

`FileDSN_name`

Is the name of Excel File Data Source Name (DSN) you wish to access.

`FileDSN_path`

Is the path to the Excel File DSN, which may reside on the hard drive or on the network.

Example: Declaring Connection Attributes

For User/System DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Excel DSN named SAMPLESERVER.

```
ENGINE SQLEXCEL SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/,
```

For File DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 using the ODBC File DSN named SAMPLESERVER.dsn.

```
ENGINE SQLEXCEL SET CONNECTION_ATTRIBUTES CON2
SAMPLESERVER.dsn /,:'filedsn=C:\ SAMPLESERVER.dsn;'
```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLEXCEL SET DEFAULT_CONNECTION connection
```

where:

`SQLEXCEL`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLEXCEL SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLEXCEL SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

`SQLEXCEL`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMAND`

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Excel Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Excel data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLEXCEL to identify the Adapter for Excel.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLEXCEL [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLEXCEL

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each Excel table or sheet that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Excel

The following list describes the synonym creation parameters for which you can supply values.

Workbook

Select a Workbook. The default is the workbook selected for the ODBC source.

You can type in a different workbook name or click on the ellipsis (...). This opens the Select Excel Workbook dialogue with the workbook name entered selected.

Filter by Object name

Selecting this option adds the Object Name parameters to the screen.

Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Table name

Is the name of the underlying object.

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

The list of tables consists of:

- Range names in the workbook.

- Sheet names. These names have a $ at the end of the name.

Example: **Sample Generated Synonym**

An Adapter for Excel synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File

```
FILENAME=ONHAND, SUFFIX=SQLEXCEL, $
  SEGMENT=ONHAND, SEGTYPE=S0, $
    FIELDNAME=PROD_NUM, ALIAS=Prod_Num, USAGE=A255V, ACTUAL=A255V,
      MISSING=ON, $
    FIELDNAME=PRODNAME, ALIAS=Prodname, USAGE=A255V, ACTUAL=A255V,
      MISSING=ON, $
    FIELDNAME=QTY_IN_STOCK, ALIAS=Qty_in_Stock, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
    FIELDNAME=PRICE, ALIAS=Price, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
    FIELDNAME=COST, ALIAS=Cost, USAGE=D20.2, ACTUAL=D8,
      MISSING=ON, $
```

Access File

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DB1,KEYS=1,WRITE=YES,$
```

Reference: **Access File Keywords**

This chart describes the keywords in the Access File for Excel.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Excel table. The value assigned to this attribute can include the name of the workbook as follows: TABLENAME=[*filename*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* Absence of the CONNECTION attribute indicates access to the default database server.

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support

Data types are specific to the underlying data source.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96

Customizing the Excel Environment

The Adapter for Excel provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Excel.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLEXCEL SET TIMEOUT {nn|0}
```

where:

`SQLEXCEL`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLEXCEL SET PASSRECS {ON|OFF}
```

where:

`SQLEXCEL`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Excel Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 25 Using the Adapter for Excel (via Direct Retrieval)

The Adapter for Excel (via direct retrieval) supports direct retrieval from Excel files (.xls and .xlsx files). The adapter uses the Apache POI, which is a Java API that provides access to Microsoft file formats.

In this chapter:

Configuring the Adapter for Excel (via Direct Retrieval)

You can configure the Adapter for Excel (via direct retrieval) from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter for Excel (via Direct Retrieval)

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. Right-click Excel (via direct retrieval), and select *Configure*.

   No input parameters are required.

   The configured adapter is added to the Adapters list in the navigation pane.

Managing Metadata for Excel (via Direct Retrieval)

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Excel worksheet that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server metadata.

Note that certain settings can affect synonym creation. For more information on the adapter settings, see *Changing Adapter Settings* on page 719.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console sidebar, click *Connect to Data*.

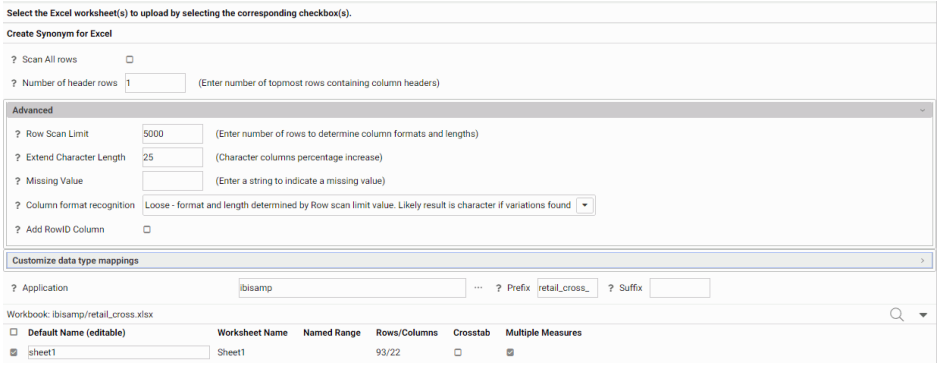
   The Adapters page opens.

2. Right-click a connection and click *Show Files*.

   A file picker dialog box opens.

3. Navigate to the application and Excel file for which you want to create the synonym and Click OK.

The *Select Excel Worksheets* page opens, as shown in the following image.



4. Enter or select values for the following parameters.

`Scan All Rows`
: If checked, scans all rows to determine data types and lengths.

`Row Scan Limit`
: Specifies the maximum number of rows to scan to determine data types and lengths. The default value is 5000.

`Extend Character Length`
: Is a percentage to add to the characters lengths to compensate for a partial scan. The default value is 25.

`Missing Value`
: Enter a string to indicate a missing value.

`Column format recognition`
: Can be Loose, to use the row scan limit to determine types and lengths, or Strict, to determine data type using the first row and the lengths using the row scan limit. The default value is Loose.

`Number of header rows`
: Enter the number of header rows containing column names. The default value is 1.

`Add RowID Column`
: If checked, adds a row number for each spreadsheet row.

`Customize data type mappings`
: If expanded, opens additional fields for decomposing date fields, adding geographic roles, and selecting the data type for numeric fields and for alphanumeric fields.

`Application`
: Enter an application name or click the ellipsis (...) to navigate to the application for the synonym.

`Prefix`

Assign a prefix to the synonym names.

`Suffix`

Assign a suffix to the synonym names.

`Workbook`

Select the workbooks for which synonyms are to be created. You can change the synonym name by selecting the default name and typing a new name.

`Crosstab`

When selected, the header rows, up to the number specified, are un-pivoted to become data values.

`Multiple Measures`

Check *Multiple Measures* if there is more than one numeric value for the titles in the last header row.

5. Click the *Create Base Synonyms* button on the ribbon.

Example: Creating a Crosstabbed Synonym

The following shows a partial Excel Spreadsheet open in the Data Management Console. The headers include Product Category, a value for Product Category, Product Subcategory, and a value for Product Subcategory.

	ROWID	REPORT_RETAIL_WF_RETAIL_LITE_RPT_FEX	FIELD_2	FIELD_3	FIELD_4	FIELD_5	FIELD_6	FIELD_7	FIELD_8
1	2	.	Product,Category	.	.	.	.	.	.
2	3	.	Accessories	.	.	Camcorder	.	.	Computers
3	4	.	Product,Subcategory	.	.	.	.	.	.
4	5	.	Charger	Headphones	Universal Remote Controls	Handheld	Professional	Standard	Smartphone
5	6	Store Name	.	.	.	.	.	.	.
6	7	Amsterdam	2724	5738	4471	6276	339	4649	4881
7	8	Anchorage	575	1269	966	1309	72	1039	1169
8	9	Arlington	420	857	750	1037	67	774	849
9	10	Athens	39	81	47	98	4	65	47
10	11	Atlanta	820	1708	1356	1923	97	1475	1674
11	12	Bangalore	79	187	144	196	7	168	121
12	13	Bangkok	1	3	4	8	2	20	7
13	14	Barcelona	92	239	145	204	10	164	130
14	15	Beijing	3	12	7	11	.	8	2
15	16	Belfast	1	6	5	2	.	6	1
16	17	Berlin	2477	5286	4370	6118	292	4558	4901
17	18	Boise	163	249	182	305	18	229	205
18	19	Boston	397	1022	723	1026	55	771	899

With Crosstab not checked, the resulting Master File has a field for column on the Spreadsheet. The following is a partial list of fields for the Spreadsheet:

```
FIELDNAME=PRODUCT_CATEGORY_ACCESSORIES_PRODUCT_SUBCATEGORY,
ALIAS='Product,Category_Accessories_Product,Subcategory', USAGE=A8V,
ACTUAL=A8V,
      MISSING=ON,
      TITLE='Product,Category_Accessories_Product,Subcategory', $
    FIELDNAME=FIELD_3, ALIAS=FIELD_3, USAGE=A12V, ACTUAL=A12V,
      MISSING=ON,
      TITLE='FIELD_3', $
    FIELDNAME=FIELD_4, ALIAS=FIELD_4, USAGE=A31V, ACTUAL=A31V,
      MISSING=ON,
      TITLE='FIELD_4', $
    FIELDNAME=CAMCORDER, ALIAS=Camcorder, USAGE=A10V, ACTUAL=A10V,
      MISSING=ON,
      TITLE='Camcorder', $
    FIELDNAME=FIELD_6, ALIAS=FIELD_6, USAGE=A15V, ACTUAL=A15V,
      MISSING=ON,
      TITLE='FIELD_6', $
    FIELDNAME=FIELD_7, ALIAS=FIELD_7, USAGE=A10V, ACTUAL=A10V,
      MISSING=ON,
      TITLE='FIELD_7', $
    FIELDNAME=COMPUTERS, ALIAS=Computers, USAGE=A12V, ACTUAL=A12V,
      MISSING=ON,
      TITLE='Computers', $
    FIELDNAME=FIELD_9, ALIAS=FIELD_9, USAGE=A7V, ACTUAL=A7V,
      MISSING=ON,
      TITLE='FIELD_9', $
    FIELDNAME=MEDIA_PLAYER, ALIAS='Media Player', USAGE=A8V, ACTUAL=A8V,
      MISSING=ON,
      TITLE='Media Player', $
```

With Crosstab checked, multiple measures unchecked, and five header rows specified, PRODUCT_CATEGORY becomes one dimension field, PRODUCT_SUBCATEGORY becomes a second dimension field, and the numeric values in the Spreadsheet become a measure field. The first column (containing store names) becomes an alphanumeric field. For example:

LOOPBACK: Data for foccache/cross_demo_sheet1. Limit 500 rows.

Double the Row Limit

	Store Name	Product Category	Product Subcategory	Measure
1	Amsterdam	Accessories	Charger	2724
2	Amsterdam	Accessories	Headphones	5738
3	Amsterdam	Accessories	Universal Remote Controls	4471
4	Amsterdam	Camcorder	Handheld	6276
5	Amsterdam	Camcorder	Professional	339
6	Amsterdam	Camcorder	Standard	4649
7	Amsterdam	Computers	Smartphone	4881
8	Amsterdam	Computers	Tablet	2841
9	Amsterdam	Media Player	Blu Ray	17439
10	Amsterdam	Media Player	DVD Players	1232
11	Amsterdam	Media Player	DVD Players - Portable	361
12	Amsterdam	Media Player	Streaming	1591
13	Amsterdam	Stereo Systems	Boom Box	619
14	Amsterdam	Stereo Systems	Home Theater Systems	10059

The resulting Master File follows:

```
FILENAME=RETAIL_CROSS_CROSS_ON, SUFFIX=DIREXCEL,
 DATASET=ibisamp/retail_cross.xlsx, BV_NAMESPACE=OFF, $
  SEGMENT=RETAIL_CROSS_CROSS_ON, SEGTYPE=S0, $
    FIELDNAME=DHL1, ALIAS=DHL1, USAGE=A20V, ACTUAL=A20V,
      MISSING=ON,
      TITLE='DHL1', $
    FIELDNAME=DVL1_PRODUCT_CATEGORY, ALIAS='Product,Category',
      USAGE=A20V, ACTUAL=A20V,
      MISSING=ON,
      TITLE='Product,Category', $
    FIELDNAME=DVL2_PRODUCT_SUBCATEGORY, ALIAS='Product,Subcategory',
      USAGE=A31V, ACTUAL=A31V,
      MISSING=ON,
      TITLE='Product,Subcategory', $
    FIELDNAME=REPORT_RETAIL_WF_RETAIL_LITE_RPT_FEX,
      ALIAS='Report retail/wf_retail_lite_rpt.fex',
      USAGE=I9, ACTUAL=A11V,
      MISSING=ON,
      TITLE='Report retail/wf_retail_lite_rpt.fex', $
  FOLDER=MG_RETAIL_CROSS_CROSS_ON, PARENT=.,
    DV_ROLE=MEASURE,
    DESCRIPTION='Measure Groups', $
  FOLDER=RETAIL_CROSS_CROSS_ON, PARENT=MG_RETAIL_CROSS_CROSS_ON,
    DESCRIPTION='Retail_cross_cross_on', $
    FIELDNAME=REPORT_RETAIL_WF_RETAIL_LITE_RPT_FEX,
      BELONGS_TO_SEGMENT=RETAIL_CROSS_CROSS_ON, $
  FOLDER=DIM_RETAIL_CROSS_CROSS_ON, PARENT=.,
    DV_ROLE=DIMENSION,
    DESCRIPTION='Dimensions', $
  FOLDER=RETAIL_CROSS_CROSS_ON1, PARENT=DIM_RETAIL_CROSS_CROSS_ON,
    DESCRIPTION='Retail_cross_cross_on', $
    FIELDNAME=DHL1, BELONGS_TO_SEGMENT=RETAIL_CROSS_CROSS_ON, $
  FOLDER=DVL, PARENT=RETAIL_CROSS_CROSS_ON1,
    DESCRIPTION='DVL', $
    FIELDNAME=DVL1_PRODUCT_CATEGORY,
      BELONGS_TO_SEGMENT=RETAIL_CROSS_CROSS_ON,
      DV_ROLE=LEVEL,  $
    FIELDNAME=DVL2_PRODUCT_SUBCATEGORY,
      BELONGS_TO_SEGMENT=RETAIL_CROSS_CROSS_ON,
      DV_ROLE=LEVEL,  $
```

You can now issue a request similar to the following:

```
TABLE FILE RETAIL_CROSS_CROSS_ON
PRINT REPORT_RETAIL_WF_RETAIL_LITE_RPT_FEX AS Measure
BY DHL1 AS Store
BY DVL1_PRODUCT_CATEGORY AS Category
BY DVL2_PRODUCT_SUBCATEGORY AS Subcategory
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```

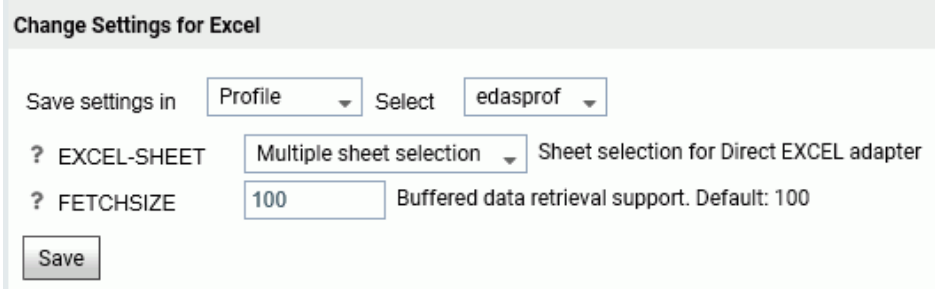
Partial output is shown in the following image.

Store	Category	Subcategory	Measure
Amsterdam	Accessories	Charger	2724
		Headphones	5738
		Universal Remote Controls	4471
	Camcorder	Handheld	6276
		Professional	339
		Standard	4649
	Computers	Smartphone	4881
		Tablet	2841
	Media Player	Blu Ray	17439
		DVD Players	1232
		DVD Players - Portable	361
		Streaming	1591
	Stereo Systems	Boom Box	619
		Home Theater Systems	10059
		Receivers	3833
		Speaker Kits	6257
		iPod Docking Station	7939
	Televisions	CRT TV	333
		Flat Panel TV	2293
		Portable TV	517
	Video Production	Video Editing	4897
Anchorage	Accessories	Charger	575
		Headphones	1269
		Universal Remote Controls	966
	Camcorder	Handheld	1309
		Professional	72
		Standard	1039
	Computers	Smartphone	1169
		Tablet	962
	Media Player	Blu Ray	3588
		Streaming	343
	Stereo Systems	Home Theater Systems	2191
		Receivers	805
		Speaker Kits	1441
		iPod Docking Station	1651
	Televisions	Flat Panel TV	459
	Video Production	Video Editing	1066

Changing Adapter Settings

To change the settings for the adapter, right-click the adapter on the Adapters page and select *Change Settings*.

The *Change Settings for Excel*page opens, as shown in the following image.



You can change the following settings.

EXCEL-SHEET

Select *Multiple sheet selection* (the default) or *Single sheet selection* from the drop-down list. Your selection affects whether you can select multiple worksheets or only a single worksheet when uploading a file using the Upload Wizard feature.

FETCHSIZE

Implements buffered retrieval. Enter a number of rows or accept the default value (100).

Select profile

Select a profile to contain these settings from the drop-down list.

Chapter 26

Using the Adapter for Facebook

This section describes how to configure the Facebook Adapter.

In this chapter:

Facebook Adapter Overview

The Facebook Adapter is used to report against information, resident in the Facebook environment. It can also be used by DataMigrator in the creation of datamarts to house Facebook information.

You can configure the Facebook Adapter using the Reporting Server Web Console. The adapter requires a connection, which stores the access token. A valid Facebook access token is needed to issue Facebook API calls. The token is associated with a Facebook application and a specific Facebook user. The access token is valid for 60 days after which a new access token would need to be obtained and configured.

The connection page shows permissions that will be granted to the Facebook application. You can uncheck permissions that should not be granted. The connection process will use only checked permissions. Authentication will take place even if no permissions are granted.

Creating a Facebook Application

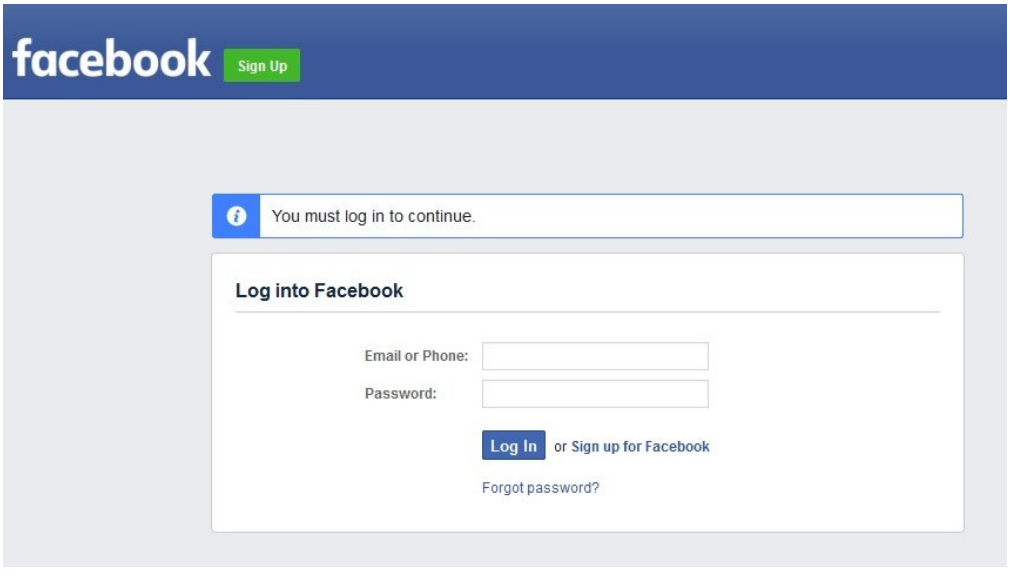
A Facebook application needs to exist before configuring the Facebook Adapter. The Facebook application must be associated with the Domain where the WebFOCUS Reporting Server is installed.

Procedure: How to Create a Facebook Application

1. From a browser, enter the following URL in a web browser:

   `https://developers.facebook.com/apps`

A Log into Facebook screen will appear if you are not already logged into Facebook, as shown in the following image.

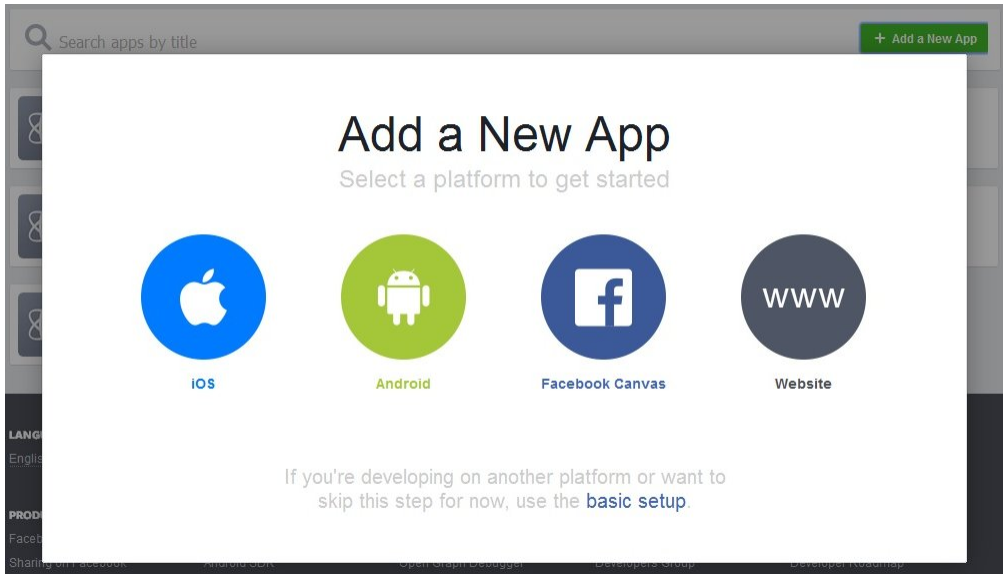


2. Enter your Facebook credentials and click *Log In*.

   The following screen is displayed.

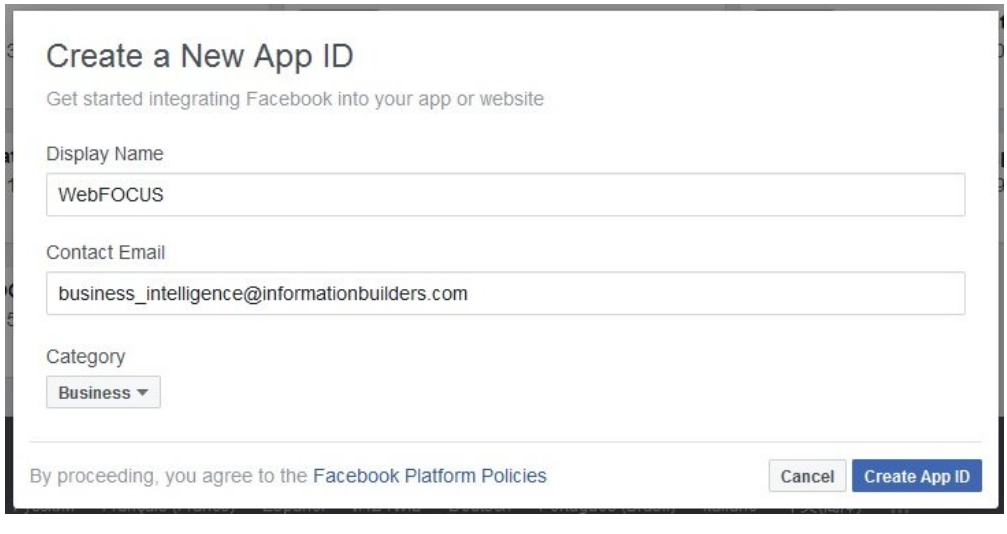
3. Click + *Add a New App*.

The Add a New App screen is displayed, as shown in the following image.



4. Click *basic setup*.

   The Create a New App ID screen is displayed, as shown in the following image



5. Perform the following steps:

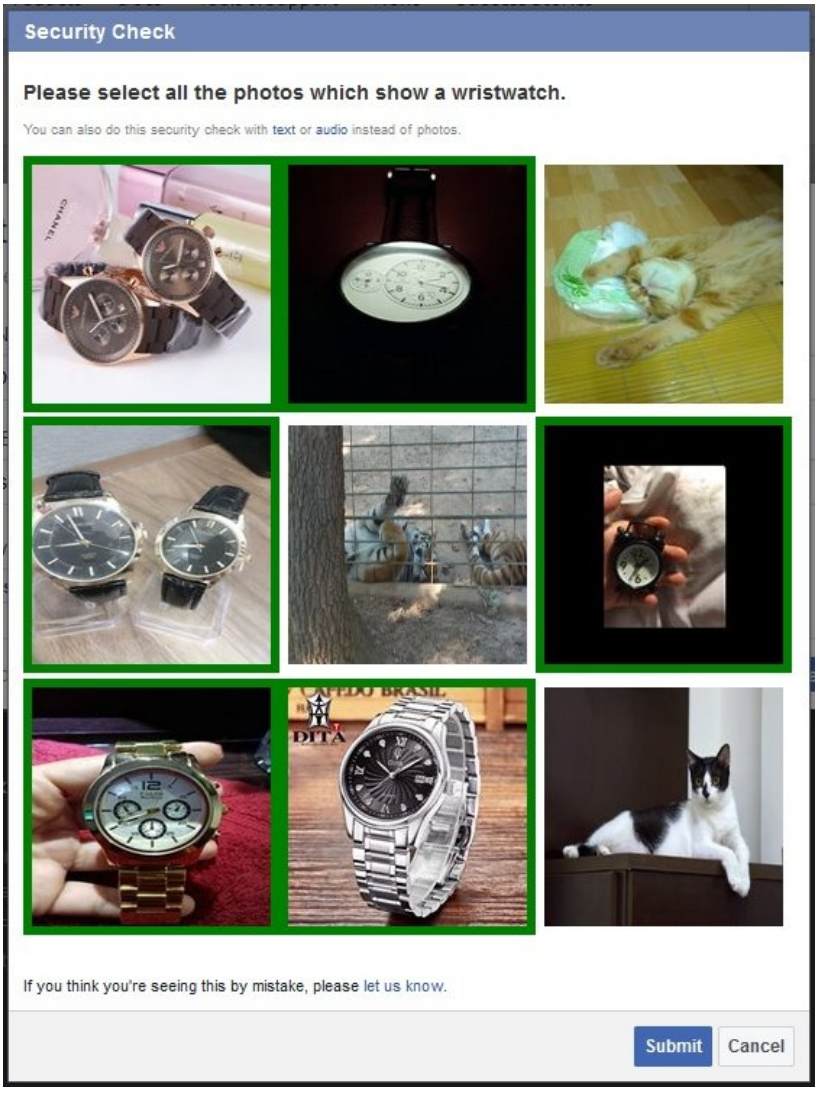
   a. Enter a name for the new Facebook application you are creating in the Display Name field.

b. Enter a valid email address in the Contact Email field.

c. Select a category for your Facebook application from the Category drop-down list.

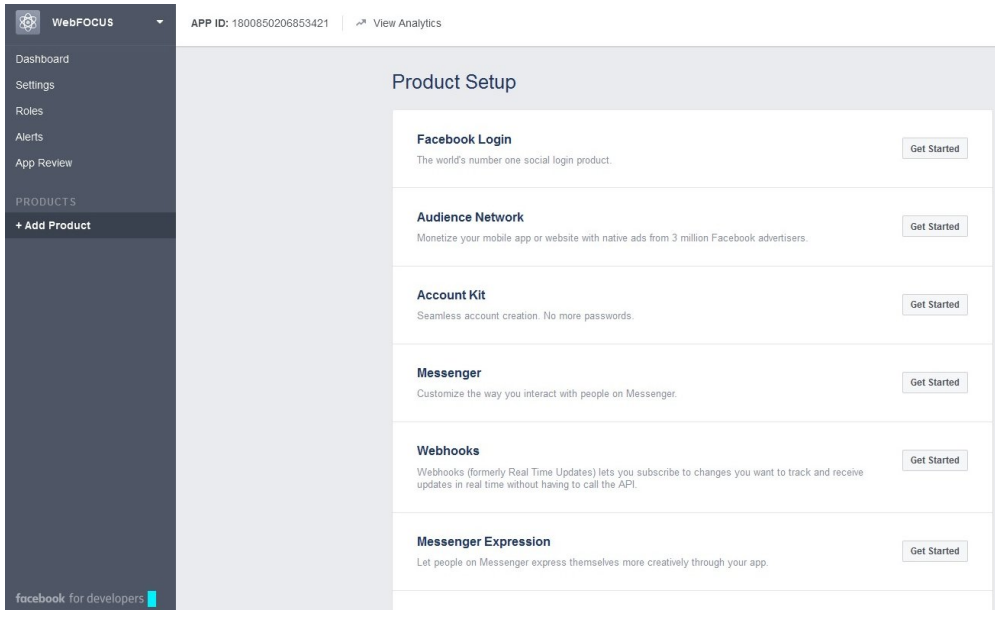
6. Click *Create App ID*.

   The Security Check screen is displayed, as shown in the following image.



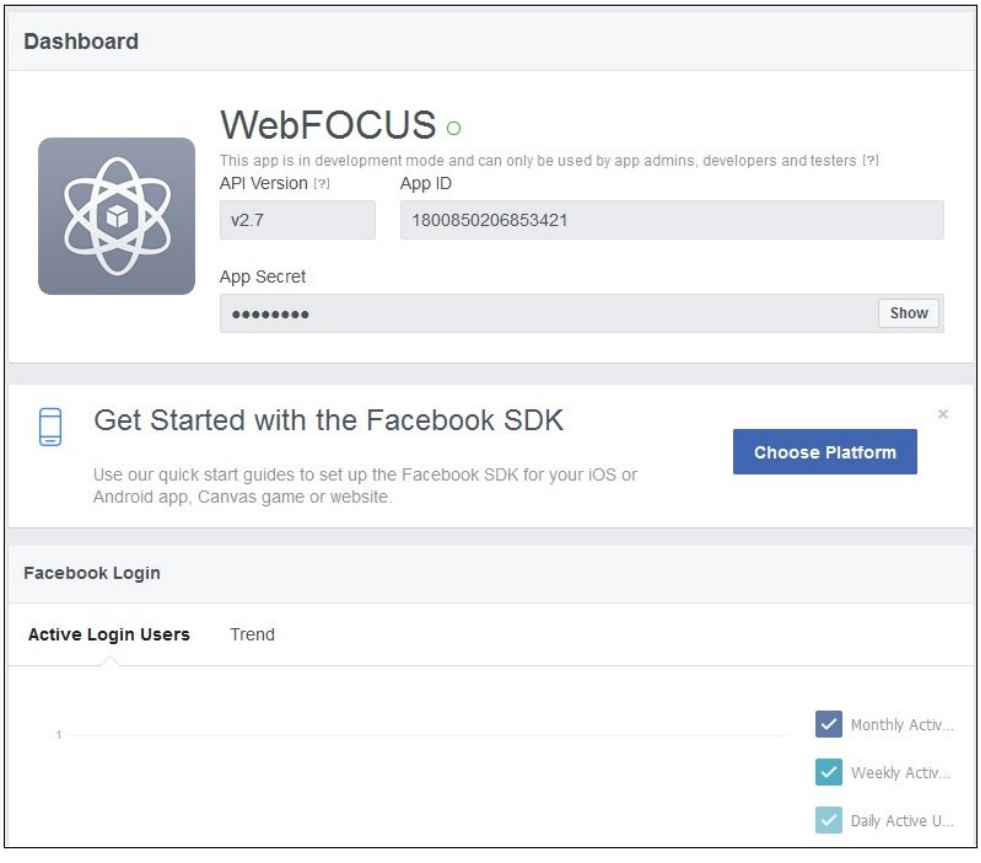
7. Click the required images as specified by the security instructions, and then click *Submit*.

The Product Setup screen is displayed, as shown in the following image.



8. Click *Dashboard* in the left pane.

The Dashboard screen is displayed and is branded based on the display name you specified in Step 5, as shown in the following image.



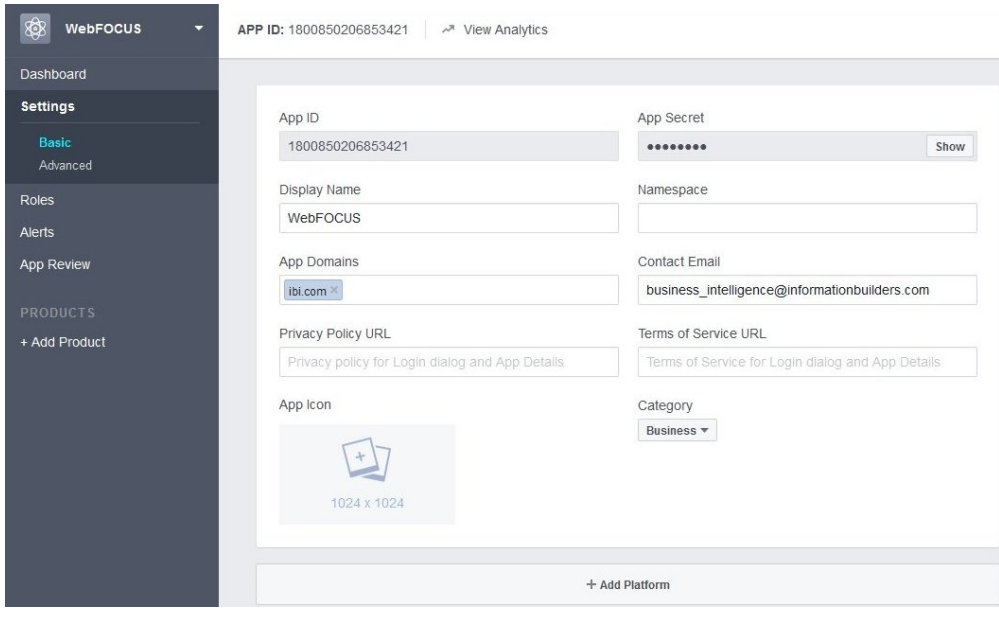
The Dashboard screen contains the App ID and App Secret values. The App Secret value is hidden by default. These values are required for configuring the Facebook Adapter.

9. To view the App Secret value, click *Show*.

   A prompt for the password of the Facebook user creating the application is displayed.

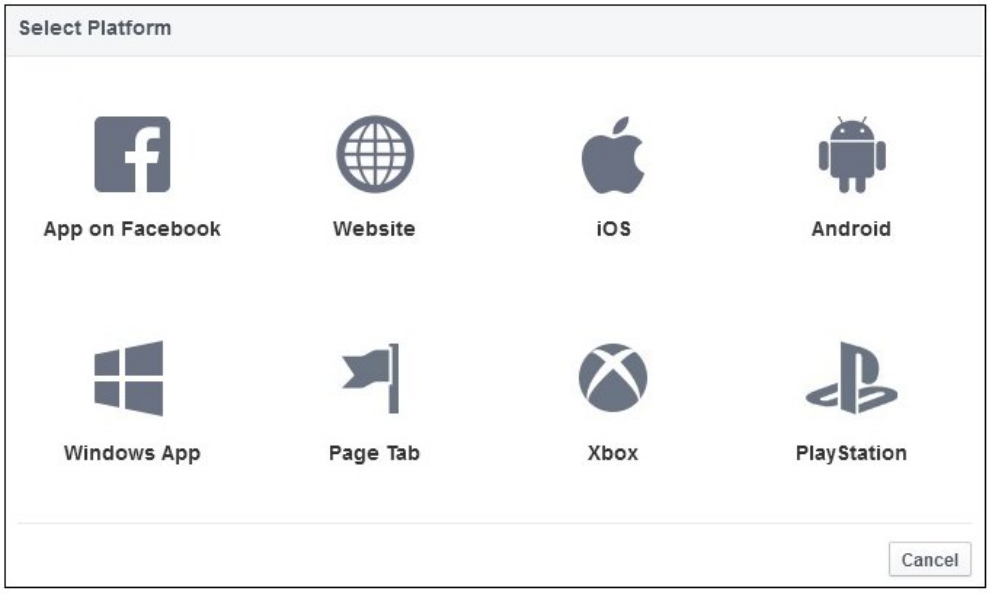
10. Enter the valid password and then click *Submit*.
11. Click *Settings* in the left pane.

The Settings screen is displayed, as shown in the following image.



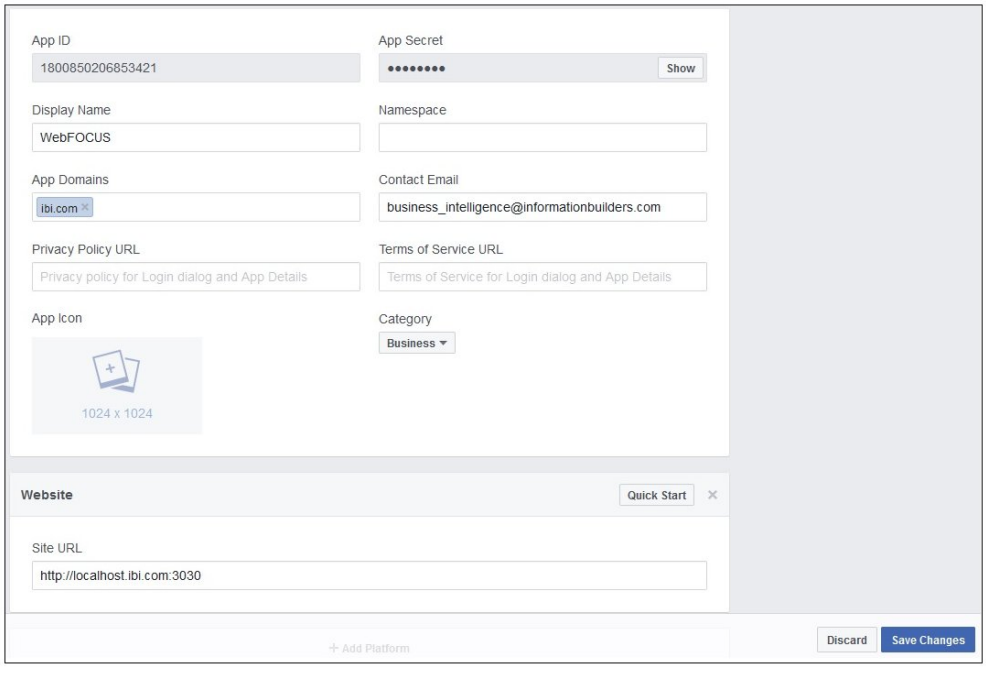
12. In the App Domains field, enter the domain where the WebFOCUS Reporting Server is installed.
13. Click + *Add Platform*.

The Select Platform screen is displayed, as shown in the following image.



14. Click *Website*.

You are returned to the Settings screen, as shown in the following image.



15. Enter a Site URL with the domain matching where the WebFOCUS Reporting Server is installed.
16. Click *Save Changes*.

    You are now ready to configure the Facebook Adapter.

Configuring the Facebook Adapter

This section describes how to configure the Facebook Adapter.

Procedure: How to Configure the Facebook Adapter

1. Clear the cookies from the web browser that will be used to start the WebFOCUS Reporting Server Web Console.
2. Access the WebFOCUS Reporting Server Web Console with a URL containing the domain where the WebFOCUS Reporting Server is installed. For more information, see *Creating a Facebook Application* on page 721.

   This domain should match the one configured with the Facebook application. For example:

   ```
   http://IBI-Computer.ibi.com:8121
   ```

3. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

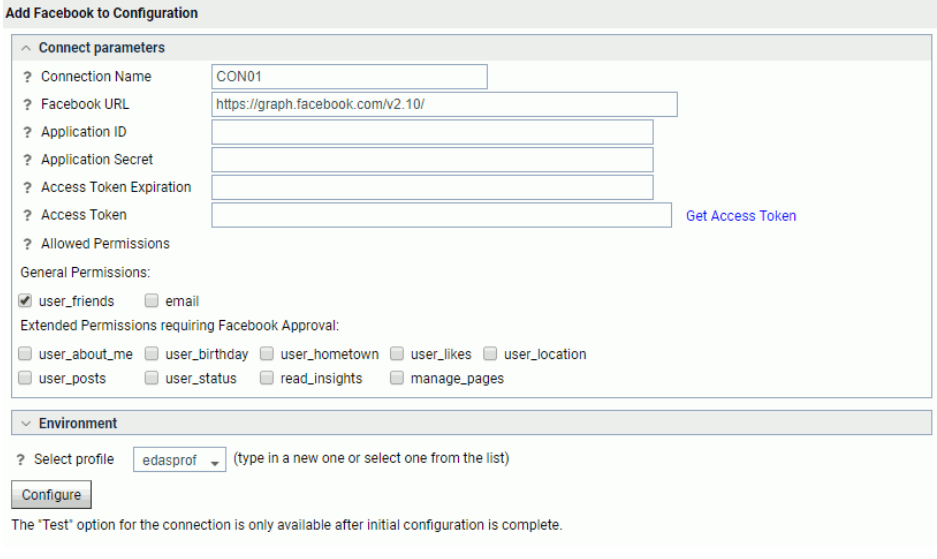
   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

4. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

5. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

6. Right-click the *Facebook* node and select *Configure*.

   The Add Facebook to Configuration pane opens, as shown in the following image.



7. Enter the values for the Application ID and Application Secret as defined in the Facebook application you created.

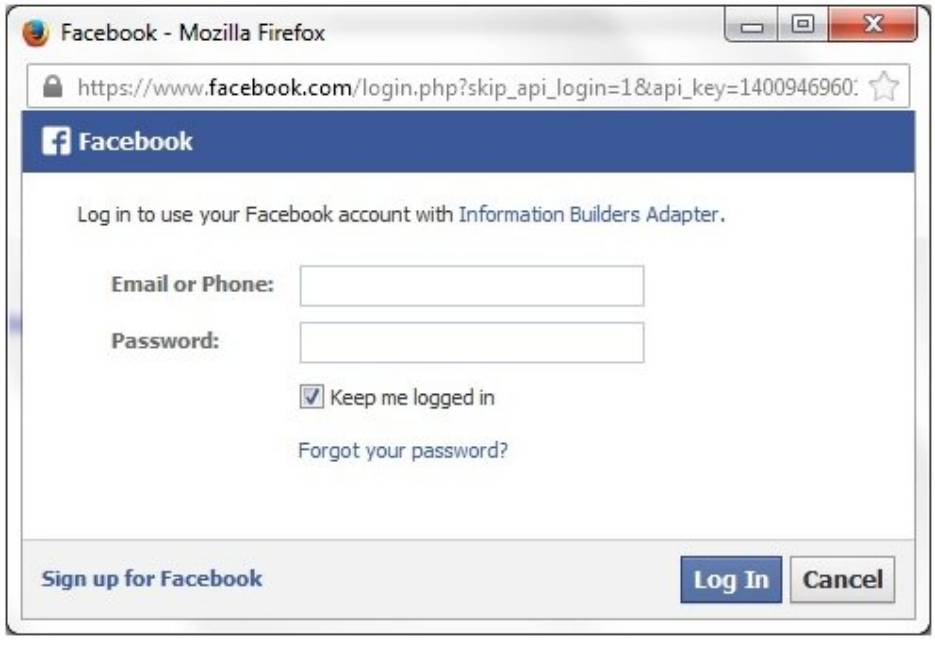
   For more information, see *Creating a Facebook Application* on page 721.

8. Choose the options in the General Permissions area and Extended Permissions that are to be granted to the Facebook Application. Note that the Extended Permissions require Facebook approval.

   Click the *Get Access Token* link.

For more information on the Allowed Permissions, see *Connection Attributes for Facebook* on page 733.

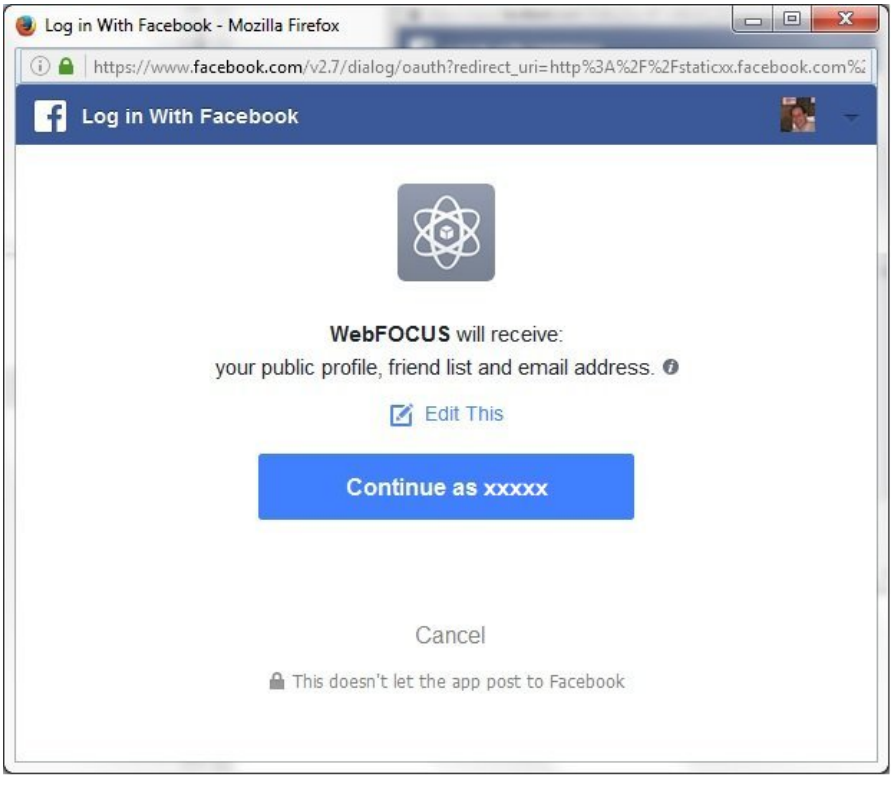
A Facebook login dialog opens, as shown in the following image.



If the Facebook login dialog does not open, ensure that the Pop-up Blocker within the web browser is either disabled or configured to allow pop-up windows from the host where the WebFOCUS Reporting Server is installed.

9. Enter the Facebook login credentials and then click *Log In*.

A pop-up window is displayed asking you to confirm the permissions that are to be granted to the Facebook application, as shown in the following image.



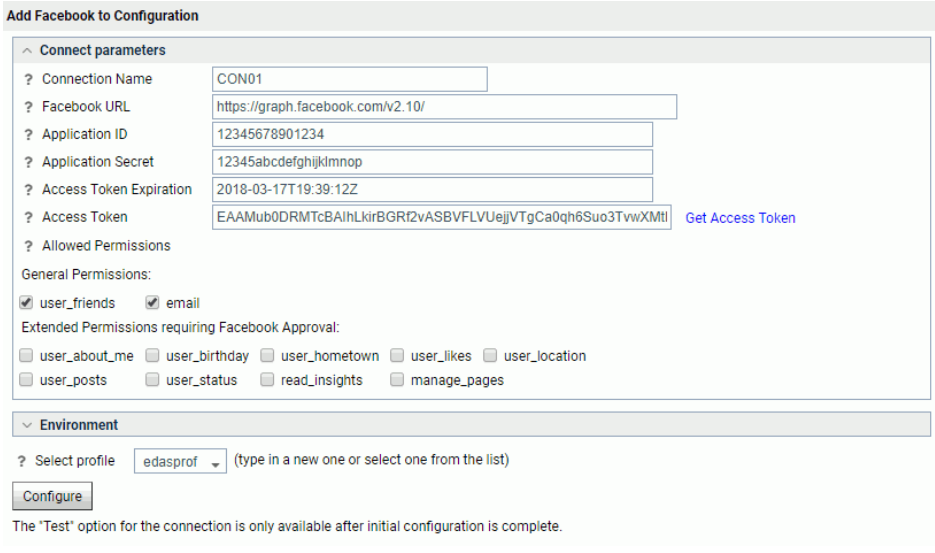
10. Click *Continue as xxxxx*.

    where:

    xxxxx

    Is the name of the Facebook user.

You are returned to the Add Facebook to Configuration pane where the Access Token Expiration and the Access Token fields are now populated, as shown in the following image.



11. Click *Configure*.

    The configured Facebook Adapter is added to the Facebook node in the left pane.

    Note: The Access Token expires after 60 days. To refresh the Access Token, click the *Get Access Token* link and then click *Configure*.

Reference: Connection Attributes for Facebook

The following list describes the connection attributes for the Facebook Adapter.

Connection Name

Logical name used to identify this particular set of connection attributes. The default is CON01.

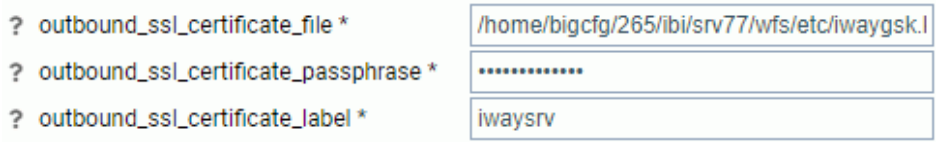
Facebook URL

The URL of the Facebook Graph API request. The default value is:

`https://graph.facebook.com/`

For iSeries machines, the WebFOCUS Reporting Server must be configured for SSL as follows:

1. From the Web Console sidebar, click *Workspace*.
2. From the menu bar, click *Workspace Set*, and select *Miscellaneous Settings*
3. Enter values for *outbound_ssl_certificate_file*, *outbound_ssl_certificate_passphrase*, and *outbound_ssl_certificate_label*, and then click *Save*. For example:



Application ID

The Facebook application ID as defined during the creation of the Facebook Application. For more information, see *Creating a Facebook Application* on page 721.

Application Secret

The Facebook application secret as defined in the Facebook application. For more information, see *Creating a Facebook Application* on page 721.

Access Token Expiration

The date and time that the Access Token will expire.

Access Token

Click the *Get Access Token* link to obtain this token. The credentials for a Facebook account are then entered. The value for the Access Token is returned by an authorized login.

General Permissions

Grants the selected permissions to the Facebook application, which include:

- ❑ user_friends
- ❑ email

Extended Permissions requiring Facebook Approval

Grants the selected permissions to the Facebook application, which include:

- ❑ user_about_me
- ❑ user_birthday

- user_hometown
- user_likes
- user_location
- user_posts
- user_status
- read_insights
- manage_pages

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the connection attributes. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), select *New Profile* from the drop-down list and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

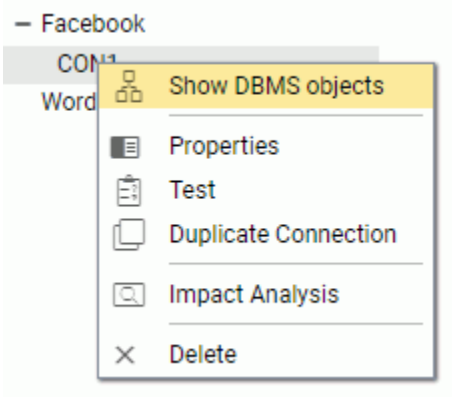
Creating Metadata and Sample Reports for the Facebook Adapter

Create Synonym for the Facebook Adapter creates the metadata used for WebFOCUS reporting and DataMigrator ETL flows. It also creates sample WebFOCUS reports and DataMigrator ETL flows.

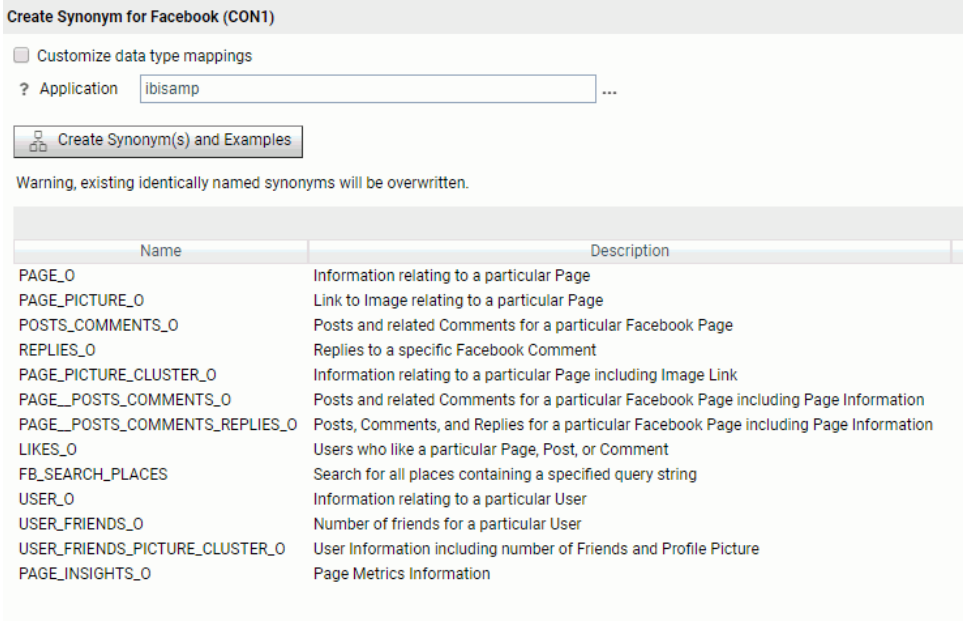
Procedure: How to Create Metadata and Sample Reports

1. From the WebFOCUS Reporting Server Web Console, expand the *Adapters* folder, *Configured* folder, and then the *Facebook* folder.

2. Right-click the configured connection for the Facebook Adapter (for example, FB) and select *Show DBMS objects* from the context menu, as shown in the following image.



The Create Synonym for Facebook pane opens, as shown in the following image.



Name	Description
PAGE_O	Information relating to a particular Page
PAGE_PICTURE_O	Link to Image relating to a particular Page
POSTS_COMMENTS_O	Posts and related Comments for a particular Facebook Page
REPLIES_O	Replies to a specific Facebook Comment
PAGE_PICTURE_CLUSTER_O	Information relating to a particular Page including Image Link
PAGE__POSTS_COMMENTS_O	Posts and related Comments for a particular Facebook Page including Page Information
PAGE__POSTS_COMMENTS_REPLIES_O	Posts, Comments, and Replies for a particular Facebook Page including Page Information
LIKES_O	Users who like a particular Page, Post, or Comment
FB_SEARCH_PLACES	Search for all places containing a specified query string
USER_O	Information relating to a particular User
USER_FRIENDS_O	Number of friends for a particular User
USER_FRIENDS_PICTURE_CLUSTER_O	User Information including number of Friends and Profile Picture
PAGE_INSIGHTS_O	Page Metrics Information

3. Enter a specific application in the Application field or click the ellipsis button to the right of the field to select an application where the metadata, sample reports, and DataMigrator ETL flows are to be stored.
4. Click *Create Synonym(s) and Examples*.

The Create Synonym for Facebook Status pane opens and indicates that the synonym was created successfully.

Facebook Adapter Examples

This section describes the metadata and sample reports for the Facebook Adapter.

Reference: Facebook Adapter Metadata

The following table lists and describes the available metadata for the Facebook Adapter.

A metadata name with a "_o" suffix is used to retrieve an object of information from Facebook. This type of metadata should only be used as a secondary file in a JOIN.

A metadata name without a "_o" suffix is used to retrieve specific columns of information from Facebook.

Metadata	Description
fb_search	Used to search for a Facebook ID for a page or user.
fb_search_places	Used to search for places containing a specified query string.
likes_o	Used to retrieve the IDs and names of users who like a given video, post, comment, link, photo, or album.
page_insights_o	Used to retrieve specific statistics about a particular Facebook page.
page_o	Used to retrieve information about a Facebook page.
page_picture_o	Used to retrieve a picture for a Facebook page or user.
posts_comments_o	Used to retrieve Posts and Comments for a Facebook page.

Metadata	Description
profile_o	Used to retrieve the name, user name/page alias, and type for a Facebook object. For example, user, group, page, event, application.
replies_o	Used to retrieve replies for comments.
user_friends_o	Used to retrieve friends for a Facebook user.
user_o	Used to retrieve information about a user.
fbsampl/fb_comment_sentiment	Describes a SQL Server table loaded by the fb_datamigrator_sentiment_load DataMigrator flow. The table contains sentiment scores for Facebook comments. Used when the WAND Sentiment Analysis Adapter is configured.
fbsampl/fb_comments	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains Facebook comments.
fbsampl/fb_comments_to_sentiment	Cluster Join from fb_comments to wandscore; wandscore metadata is created from the WAND Sentiment Analysis Adapter. Used by the fb_datamigrator_sentiment_load DataMigrator flow.
fbsampl/ fb_join_datamodel_excluding_sentiment	Cluster Join used for reporting post, posters, comments, commenters, replies, and repliers. Joins: ❑ fb_posts to fb_profile ❑ fb_posts to fb_page_info ❑ fb_posts to fb_comments ❑ fb_comments to fb_profile ❑ fb_comments to fb_replies ❑ fb_replies to fb_profile

Metadata	Description
fbsampl/ fb_join_datamodel_including_sentiment	Cluster Join used for reporting post, posters, comments, commenters, replies, repliers, post sentiment score, comment sentiment score, and reply sentiment score. Joins: ❏ fb_posts to fb_profile ❏ fb_posts to fb_page_info ❏ fb_posts to fb_comments ❏ fb_comments to fb_profile ❏ fb_comments to fb_replies ❏ fb_replies to fb_profile ❏ fb_posts to fb_post_sentiment ❏ fb_comments to fb_comment_sentiment ❏ fb_replies to fb_comment_sentiment Used when the WAND Sentiment Analysis Adapter is configured.
fbsampl/fb_page_info	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains Facebook page information.
fbsampl/fb_post_sentiment	Describes a SQL Server table loaded by the fb_datamigrator_sentiment_load DataMigrator flow. The table contains sentiment scores for Facebook posts. Used when the WAND Sentiment Analysis Adapter is configured.
fbsampl/fb_posts	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains Facebook posts.

Metadata	Description
fbsampl/fb_posts_to_sentiment	Cluster Join from fb_posts to wandscore; wandscore metadata is created from the WAND Sentiment Analysis Adapter. Used by the fb_datamigrator_sentiment_load DataMigrator flow.
fbsampl/fb_profile	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains name, user name/page alias, and type information for a Facebook object. For example, user, group, page, event, application.
fbsampl/fb_replies	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains Facebook replies.
fbsampl/fb_replies_to_sentiment	Cluster Join from fb_replies to wandscore; wandscore metadata is created from the WAND Sentiment Analysis Adapter. Used by the fb_datamigrator_sentiment_load DataMigrator flow.
fbsampl/fb_user	Describes a SQL Server table loaded by the fb_datamigrator_load DataMigrator flow. The table contains user information.
fbsampl/page_insights_cluster	Cluster Join used for reporting page and page statistics. Joins: page_o to page_insights_o
page_picture_cluster_o	Cluster Join used for reporting page and page picture statistics. Joins: page_o to page_picture_o

Metadata	Description
fbsampl/page_posts_comments_o	Cluster Join used for reporting page posts and comments. Joins: page_o to posts_comments_o
fbsampl/posts_comments_replies_o	Cluster Join used for reporting page, posts, comments, and replies. Joins: ❏ page_o to posts_comments_o ❏ posts_comments_o to replies_o
fbsampl/ user_friends_picture_cluster_o	Cluster Join for reporting user information, number of friends, and user picture. Joins: ❏ user_o to user_friends_o ❏ user_o to page_picture_o
fbsampl/ user_picture_cluster_o	Cluster Join for reporting user information and user picture. Joins: user_o to page_picture_o

Reference: Facebook Adapter Sample Reports

The following table lists and describes the sample reports for the Facebook Adapter.

Sample Report	Description
fbsampl/fb_create_datamodel	Creates the SQL Server tables used for the Facebook data model loaded by the fb_datamigrator_load and fb_datamigrator_sentiment_load DataMigrator flows. As a prerequisite, a SQL Server connection called *socialmedia* must be configured as well as the creation of a SQL Server database called *Facebook*.
fbsampl/fb_delete_datamodel	Deletes the SQL Server tables used for the data model.
fbsampl/fb_page_drill	Page information drill report. Uses: fbsampl/fb_page_info
fbsampl/fb_page_posts_comments_replies_report	Reports Facebook page posts with related comments and replies. Uses: fbsampl/fb_join_datamodel_excluding_sentiment
fbsampl/fb_page_posts_comments_replies_scored_report	Reports Facebook page posts with related comments and replies including sentiment scoring. Uses: fbsampl/fb_join_datamodel_including_sentiment
fbsampl/fb_search	Search for the ID and name for a page or user. Uses fb_search.

Sample Report	Description
fbsampl/fb_search_places	Search for places containing a specified query string. Uses: fb_search_places
fbsampl/fb_tagcloud_drill_excluding_sentiment	Drill to posts, comments, and replies from the tag cloud. The Words Analysis adapter must be configured. Uses: fbsampl/fb_join_datamodel_excluding_sentiment
fbsampl/fb_tagcloud_drill_including_sentiment	Drill to posts, comments, replies, and sentiment from the tag cloud. The Words Analysis adapter must be configured. Uses: fbsampl/fb_join_datamodel_including_sentiment
fbsampl/fb_tagcloud_drill_post_excluding_sentiment	Reports on a specific post with related comments and replies. The Words Analysis adapter must be configured. Uses: fbsampl/fb_join_datamodel_excluding_sentiment
fbsampl/fb_tagcloud_drill_post_including_sentiment	Reports on a specific post with related comments, replies, and sentiment. The Words Analysis adapter must be configured. Uses: fbsampl/fb_join_datamodel_including_sentiment

Sample Report	Description
fbsampl/fb_tagcloud_posts_comments_replies	Tag cloud graph for posts, comments, and replies. The Words Analysis adapter must be configured. Uses: fbsampl/fb_join_datamodel_excluding_sentiment wan_document (Words Analysis metadata)
fbsampl/fb_user_drill	User information drill report. Uses: fbsampl/fb_user
fbsampl/page_insights_o	Reports metrics for a specific page. Uses: fbsampl/page_insights_cluster_o
page_o	Reports page information for a specific page. Uses: fbsampl/page_picture_cluster_o
fbsampl/page_posts_comments_o	Reports Facebook page posts and related comments. Uses: fbsampl/page_posts_comments_o
fbsampl/page_posts_comments_replies_o	Reports Facebook page posts and related comments including replies. Uses: fbsampl/page_posts_comments_replies_o
fbsampl/page_posts_likes_o	Reports users who liked particular posts. Uses: fbsampl/page_posts_comments_o and likes_o

Sample Report	Description
fbsampl/profile_o	Reports the type for an Object ID (Page or User). Uses: profile_o
fbsampl/user_o	Reports user information for a Facebook user. Uses: fbsampl/user_friends_picture_cluster_o

Reference: **Facebook Adapter DataMigrator Flows**

The following table lists and describes the DataMigrator flows for the Facebook Adapter. The Facebook Data Model must first be created by running fbsampl/fb_create_datamodel.

Flow	Description
fbsampl/fb_datamigrator_load	Process flow to run the following data flows: ❑ fbsampl/fb_load_page ❑ fbsampl/fb_load_posts ❑ fbsampl/fb_load_comments_replies ❑ fbsampl/fb_load_profile_posters ❑ fbsampl/fb_load_profile_commenters ❑ fbsampl/fb_load_profile_repliers ❑ fbsampl/fb_load_pages ❑ fbsampl/fb_load_users

Flow	Description
fbsampl/ fb_datamigrator_sentiment_load	Process flow to run the following data flows: ❑ fbsampl/fb_load_post_sentiment ❑ fbsampl/fb_load_comment_sentiment ❑ fbsampl/fb_load_reply_sentiment
fbsampl/ fb_load_comment_sentiment	Data flow to load sentiment scores for Facebook comments.
fbsampl/fb_load_comments_replies	Data flow to load Facebook comments and replies.
fbsampl/fb_load_page	Data flow to load Facebook page information for pages identified in the fbsampl/page_ids.ftm file.
fbsampl/fb_load_pages	Data flow to load Facebook page information for people that have either posted, commented, or replied from a Facebook page.
fbsampl/fb_load_post_sentiment	Data flow to load sentiment scores for Facebook posts.
fbsampl/fb_load_posts	Data flow to load Facebook posts.
fbsampl/ fb_load_profile_commenters	Data flow to load Facebook user and page profile information for commenters. For example, ID, name, and commenter type (page/user).
fbsampl/fb_load_profile_posters	Data flow to load Facebook user and page profile information for posters. For example, ID, name, and poster type (page/user).
fbsampl/fb_load_profile_repliers	Data flow to load Facebook user and page profile information for repliers. For example, ID, name, and replier type (page/user).
fbsampl/fb_load_reply_sentiment	Data flow to load sentiment scores for Facebook replies.

Flow	Description
fbsampl/fb_load_users	Data flow to load Facebook user information for people that have either posted, commented, or replied.

Chapter 27 Using the Adapters for Fixed-Format and Delimited Files

The Adapters for Fixed-Format and Delimited Flat Files access sequential files, where records are stored and retrieved in the same order as they are entered. Sequential data sources may be:

- Fixed-format files (identified as flat files in prior releases), in which each field occupies a predefined position in the record. (To maintain the fixed structure, unoccupied positions are filled by blanks.)
- Delimited-format files (identified as delimited files in this chapter), in which fields are stored in a predefined sequence, separated (that is, delimited) by a special character. (Although fields must maintain their predefined order in the file, blanks are not required to represent unoccupied positions.)

The adapters convert application requests into input/output (I/O) calls and return optimized answer sets to the requesting application.

You can also access compressed data sets with this adapter. However, the actual compression is done using the ZCOMP Exit. For details, see *Data Set Compression Exit: ZCOMP* on page 2719.

In this chapter:

Preparing the Fixed-Format and Delimited File Environment

The Adapters for Fixed-Format and Delimited Files do not require setting any environment variables.

Configuring the Adapters for Fixed-Format and Delimited Files

You can configure the Adapters for Fixed-Format and Delimited Files from the Web Console or the Data Management Console. In addition, for each type of file, you must specify the location of the data files you wish to access. You can define the location, either by:

- Including a FILEDEF command in a supported server profile. This approach enables you to quickly change the physical file name associated with the metadata.

- Specifying the location when you create a synonym. This approach enables you to define the data file location in the Master File.

Procedure: How to Configure the Adapters for Fixed-Format and Delimited Files

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note: The Fixed-Format Files and Delimited Files adapters are under the *Sequential and Indexed* group folder. No input parameters are required.

Procedure: How to Configure a Connection to an FTP Server for Delimited and Fixed-Format Files From the Web Console or the Data Management Console

An FTP Server can be used as a source for delimited and flat files by configuring a connection to the server. First, you must configure an adapter.

To configure a connection to an FTP server:

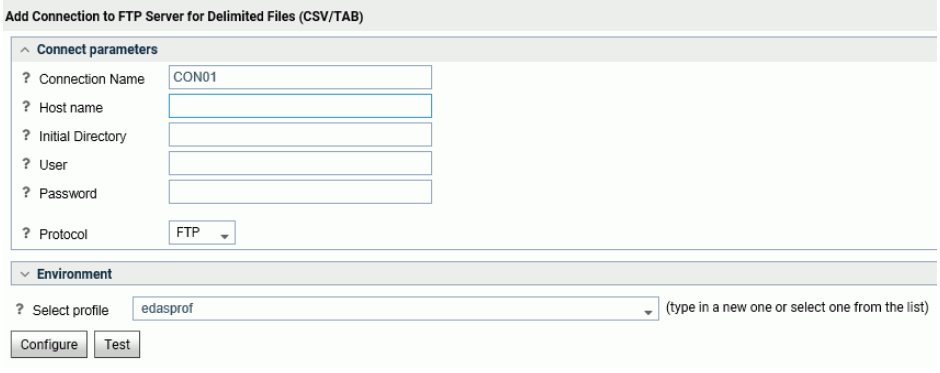
1. From the Web Console Applications page, click *Get Data*.

or

From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. Right-click the *Fixed-Format Files* or *Delimited Files* folder and select *Add Connection*.
3. The Add Connection to FTP Server for... window opens



4. Enter the Connection Parameters. See the *FTP Connection Parameters* below for details.
5. Click *Configure*.

Reference: FTP Connection Parameters

These are the connection parameters for FTP.

Parameter	Value
Connection Name	Name for this connection, default is CON01 **Note:** To use the Connection Name, you need to specify it in the CONNECTION attribute of the synonym located in the Data Allocation section.
Host Name	Name or IP address of FTP Server
Initial Directory	Directory on FTP server on initial connection
User	User ID to connect to FTP server or anonymous
Password	Password to connect to FTP or an email address

Parameter	Value
Profile	Profile on server to add this connection

Syntax: How to Specify the Location of a Fixed-Format or Delimited File on UNIX, Windows, or in an IBM i IFS or z/OS HFS File System

FIXED data sets may be allocated with the FILEDEF command

```
FILEDEF FILE1 DISK filename [(LRECL lrecl RECFM recfm]
```

where:

filename

Is the full path and file name of the data file.

lrecl

Is the record length in bytes. This parameter is optional. If you omit it, it is calculated based on the metadata description.

The left parenthesis preceding the optional parameters is required.

recfm

Is the record format. Specify F for fixed format, V for variable format. This parameter is optional. If you omit it, the default is fixed format.

Syntax: How to Specify the Location of a Fixed-Format or Delimited File in a z/OS PDS or Data Set

FIXED data sets may be allocated using JCL

```
//FILE1 DD DISP=SHR, DSN=dataset_name
```

or file definition

```
FILEDEF FILE1 DISK //'dataset_name' [(LRECL lrecl RECFM recfm]
```

where:

dataset_name

Is the fully qualified data set name.

Managing Metadata for Fixed-Format and Delimited Files

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Fixed-Format or Delimited Files data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Fixed-Format or Delimited File that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File that represents the server metadata.

Creating Synonyms for Fixed-Format Files

A Fixed-Format file is a sequential file in which each field occupies a predefined position in the record, with unoccupied positions filled by blanks to maintain the fixed structure.

Procedure: How to Create a Synonym for a Fixed-Format File

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Web Console or the Data Management Console.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.

- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
   - For Windows, UNIX, and IBM i, see *Synonym Creation Parameters for Fixed-Format Files on Windows, UNIX, and IBM i IFS File Systems* on page 754.
   - For z/OS, see *Synonym Creation Parameters for Fixed-Format Files on z/OS* on page 758.
4. After entering the parameter values, click *Create Synonym*.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the *Validate* check box, the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Fixed-Format Files on Windows, UNIX, and IBM i IFS File Systems

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Cobol FD

Path to the directory containing multiple COBOL files.

Customize COBOL FD conversion options

Select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select this check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Select Data Files Allocation

Choose one of two options:

- **Single File** defines a single data file. This option is not applicable for remote connections.
- **Collection of files** defines a collection of data files to be described by one synonym.

Select Data Processing Mode

Indicates the data retrieval type.

- **One-time retrieval** retrieves data once in order to create synonym for sequential file.
- **File Listener** provides continued retrieval.

File Listener attributes

Listening directory polling interval for new files

Indicates how often the listener will check for the presence of a file in number of seconds. The default is 10 seconds.

Timeout interval in listening directory for new files

Indicates the timeout interval for the listener in number of seconds. The default is 10 seconds.

Maximum number of records processed in the request

Indicates the number of records processed within one request. This option is available for single file processing.

Maximum number of data files processed in the request

Indicates number of files processed within one request. This option is available for processing collection of files. The default is 99,999,999.

Data Files Pickup Strategy

Indicates the mechanism used by files agents to pick up files from their directories.

- **IMMEDIATE** processes the file as soon as it is detected.
- **TRIGGER** processes the file as soon as a trigger file is detected. This option requires an additional setting for the trigger file extension.

  Note: In OpenVMS, a dot (.) cannot be a part of a file name (that is, the file name prior to the extension). If the trigger file name for a listener includes a dot, the dot will be replaced with an underscore (_). For example, if a user enters file1.ext1.trig for the trigger file name, DataMigrator will replace it with file1_ext1.trig.

Trigger File Extension

Indicates the extension of the trigger file. The trigger file extension is added to the full name of the file being listened for.

Processed Data Files Discard Strategy

Indicates how the file is handled after it has been processed by a file agent.

- **DELETE** deletes the file.
- **ARCHIVE** copies the file with the timestamp to a specified directory defined in *File Listener Archiving Directory* option.
- **KEEP** keeps the files.

File Listener Archiving Directory

Defines the location where the data files will be archived when DISCARD strategy of ARCHIVE is used. This can be an application directory, a mapped application name, or a directory location on your file system.

When using a directory on a file system for local files, the name of the physical directory can be used.

When using a directory on a file system for remote data files, a directory relative to the initial directory can be used. For example, if your remote initial directory is /home/user1/apps, using *sales* will set the data files directory location to /home/user1/apps/sales.

Collection Definition attributes

Directory or Application

Defines the location of data files for polling. This can be an application directory, a mapped application name, or a directory location on your file system.

When using a directory on a file system for local files, the name of the physical directory can be used.

When using a directory on a file system for remote data files, a directory relative to the initial directory can be used. For example, if your remote initial directory is /home/user1/apps, using *sales* will set the data files directory location to /home/user1/apps/sales.

File Selection Mask attributes

These attributes allow you to limit the list of data files.

Name

Type a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.

Extension

Type an extension with or without the wildcard symbol %.

Synonym field names processing options

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Synonym Name

Indicates the name of the synonym.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Extended data format attributes

Codepage

This option provides data portability between servers by enabling processing of data loaded in different encoding systems.

Click the *Extended data format attributes* check box to display the *Codepage* option.

In the input box provided, enter the code page of the stored data. Your entry is added to the Master File of the generated synonym.

Note: The code page must have a customized conversion table as part of your NLS configuration. If you have not already requested a conversion table for the designated code page, you can do so now. On the Web Console menu bar, click *Workspace*, then *Configuration*, and choose *NLS* under General settings. The NLS Configuration Wizard opens. Click *Customize code page conversion tables* and select the check box for the code page you wish to use. Click the *Save and Restart* button to implement your new setting.

Reference: Synonym Creation Parameters for Fixed-Format Files on z/OS

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

File System Selection

Choose one of the following options from the drop-down menu:

- *Fully qualified PDS name* to indicate a partitioned data set on MVS.

  In the input boxes provided, type a PDS name preceded by // and a Member name containing the location of the COBOL FD source. If you wish, you can filter the member name using a wildcard character (%).

- *Absolute HFS directory pathname* to indicate a hierarchical file structure on USS.

  In the input boxes provided, type a Directory name to specify the HFS location that contains the COBOL FD and a File name and File extension. If you wish, you can filter the file and extension using a wildcard character (%).

Synonym field name processing options

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize options

Select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Extended data format attributes

Codepage

This option provides data portability between servers by enabling processing of data loaded in different encoding systems.

Click the *Extended data format attributes* check box to display the *Codepage* option.

In the input box provided, enter the code page of the stored data. Your entry is added to the Master File of the generated synonym.

Note: The code page you specify here must be one for which you have requested a customized code page conversion table as part of your NLS configuration. If you have not already requested a conversion table for the designated code page, you can do so now. On the Web Console menu bar, click *Workspace*, then *Configuration*, and choose *NLS* under General settings. The NLS Configuration Wizard opens. Click *Customize code page conversion tables* and select the check box for the code page you wish to use. Click the *Save and Restart* button to implement your new setting.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select files

Select files for which you wish to create synonyms:

- To select all files in the list, click the *Select All* button.
- To select specific files, select the corresponding check boxes.

Choose Data File Name

After choosing files, choose the corresponding data file name from the drop-down list.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Creating Synonyms for Delimited Files

A delimited file is a sequential file in which fields are stored in a predefined sequence, separated (that is, delimited) by a special character or characters. (Although fields must maintain their predefined order in the file, and delimiters are required, blanks are not required to represent unoccupied positions.

The types of field delimiters are:

- Comma.
- Tab.
- | (pipe)
- Token, which is any combination of characters defined in the data source Synonym. (Note that token-delimited files cannot be used in Joins.)

You can create different types of synonyms using the Adapter for Delimited Files:

- A synonym for a file that resides on a server or on a local machine.
- A synonym for a collection of files with a one-time retrieval.
- A synonym for a collection of files for a File Listener.
- Multiple Synonyms.

Procedure: How to Create a Synonym for a Delimited File

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Web Console or the Data Management Console.

1. From the Web Console menu bar, click *Applications*, then *New,* and then *Synonym*

   or

   From the Data Management Console, right-click an application directory, then select *New*, and then *Synonym*.

   The *Select Data File for Delimited Flat File Synonym* pane opens.
2. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.
3. After entering the parameter values, click *Create Synonym*.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note: You can also create a synonym from the Adapters page by right-clicking a configured adapter connection and selecting *Create Synonym*.

Reference: Synonym Creation Parameters for Delimited Files

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the *Next* button, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Create Multiple Synonyms

Select this check box for Multiple Synonyms.

Data Files location

Is the path to multiple data files.

File location

Defines the location of the data file.

From the drop-down menu select:

- **Server side.**
- **Local machine.**

Data File

Defines an absolute path to the data file on the server or a directory relative to the initial one. It includes the name of the data file.

Enter the path and file name or click the ellipsis (...) to select the file.

Upload file

Click the ellipsis (...) to select the data file to be uploaded.

Select Data Files Allocation

Select:

- **Single File** to define a single data file. This option is not applicable for remote connections.
- **Collection of files** to define a collection of data files to be described by one synonym.

Select Data Processing Mode

Indicates the data retrieval type:

- **One-time retrieval** retrieves data once, in order to create a synonym for a sequential file.

- **File Listener** provides continual retrieval.

Record Specification

Record Delimiter

Defines a character or series of characters that indicate the separation between file records or data rows (for example, groups of delimited fields).

This attribute is reflected in the Access File as RDELIMITER.

Non-printable Record Delimiter

Defines whether the string in the delimiter field is a printable string or a non-printable decimal character. Please note that a non-printable decimal character will appear (translated) in the Access file as a hexadecimal value. If the delimiter is entered as hexadecimal, set this attribute to *No*.

Field Specification

Delimiter

Defines a character or series of characters that indicate the separation between file fields.

To use multiple characters, enter them together. For example enter two slashes (//).

To use a tab character as a delimiter, enter the reserved word TAB.

Alternatively, you can enter hexadecimal values directly. For example, Linefeed and Carriage Return would be 0x0A and 0x0D, respectively.

If several characters form a separator, enter then as one string. For example, Linefeed and Carriage Return would be 0x0A0D.

Non-printable Delimiter

Defines whether the string in the delimiter field is a printable string or a non-printable decimal character. Please note that the non-printable decimal character will appear (translated) in the Access file as a hexadecimal value.

If the delimiter is entered as a hexadecimal value, set this attribute to *No*.

If this attribute is set to *Yes*, then the values in the *Delimiter* attribute should be entered as decimals. For example, for non-printable separators such as Linefeed, use the decimal value of 10. If several non-printable characters form a separator, use a space between the decimal values. For example, to use Linefeed and Carriage Return together, enter 10 or 13.

Header Row

Select this check box to request that names in the header line be used as column names in the synonym.

`Number of first rows to skip`

Specifies the number of rows above the header row that should be ignored when creating the synonym and reading the data.

Enclosure

If character columns are enclosed in quotation marks or another symbol, enter an enclosure symbol for the character column format used in the delimited file(s) for which the synonyms are being generated. For example, for a file in which character columns are enclosed in double quotation marks, specify " in the *Enclosure* field.

Record Scan Limit

Enter a value to indicate how many records from the DFIX data file to scan to determine the length of the columns.

If this parameter is omitted, all records from the file are processed to make this determination.

Preserve format

Indicates whether the original data layout, including empty records and linefeeds, will be preserved.

- *No*. The original characters will be replaced by a printable string. This is the default.
- *Yes*. The original characters, including non-printable characters and linefeeds, will be preserved.

This attribute is reflected in the Access File as PRESERVEFRMT.

File Listener

Listening directory polling interval for new files

Indicates how often the listener will check for the presence of a file in number of seconds. The default is 10 seconds.

Timeout interval in listening directory for new files

Indicates the timeout interval for the listener in number of seconds. The default is 10 seconds.

Maximum number of data files processed in the request

Indicates number of files processed within one request. The default is 99,999,999.

Data Files Pickup Strategy

Indicates the mechanism used by files agents to pick up files from their directories.

- **IMMEDIATE** processes the file as soon as it is detected.
- **TRIGGER** processes the file as soon as a trigger file is detected. This option requires an additional setting for the trigger file extension.

  Note: In OpenVMS, a dot (.) cannot be a part of a file name (that is, the file name prior to the extension). If the trigger file name for a listener includes a dot, the dot will be replaced with an underscore (_). For example, if a user enters file1.ext1.trig for the trigger file name, DataMigrator will replace it with file1_ext1.trig.

Trigger File Extension

Indicates the extension of the trigger file. The trigger file extension is added to the full name of the file being listened for.

Processed Data Files Discard Strategy

Indicates how the file is handled after it has been processed by a file agent.

- **DELETE** deletes the file.
- **ARCHIVE** copies the file with the timestamp to a specified directory defined in File Listener Archiving Directory option.
- **KEEP** keeps the files.

File Listener Archiving Directory

Archiving directory on the server where the data file will be archived. You can use an absolute path or a directory relative to the initial one.

Collection Definition

Directory or Application

Defines the location type of the data files. It can be a physical directory for local files or a directory relative to the initial directory for remote data files. For example, if your remote initial directory is /home/user1/apps, using sales in collection definition will set the data files location to /home/user1/apps/sales.

File Selection Mask

Name

Type a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.

Extension

Type an extension with or without the wildcard symbol %.

Synonym field names processing options

Application

Select an application directory. The default value is *baseapp*.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Select files

Select the check boxes to left of *Default Synonym Name* to choose the files for which you want to create synonyms. The data files are highlighted when you choose the corresponding check boxes.

Click *Select All Files* to select all the data files in the directory path.

Extended data format attributes

Codepage

This option provides data portability between servers by enabling processing of data loaded in different encoding systems.

Select the *Extended data format attributes* check box to display the Codepage option.

In the input box provided, enter the code page of the stored data. Your entry is added to the Master File of the generated synonym.

Note: The code page you specify here must be one for which you have requested a customized code page conversion table as part of your NLS configuration. If you have not already requested a conversion table for the designated code page, you can do so now. From the Web Console *Workspace* menu, select *Configuration/Monitor*. In the navigation pane, right-click *NLS* and select *Configure*. The NLS Configuration Wizard opens. Click *Customize code page conversion tables* and select the check box for the code page you wish to use. Click *Save and Restart Server* to implement your new setting.

Example: Sample DFIX Data File and Generated Synonym

This example is for a single synonym for a file on the serve.

DFIX data file (Comma-delimited):

```
ENGLAND,JAGUAR,V12XKE AUTO,CONVERTIBLE,2,7427,8878.0
ENGLAND,JAGUAR,XJ12L AUTO,SEDAN,5,11194,13491,12000
ENGLAND,JENSEN,INTERCEPTOR III,SEDAN,4,14940,17850,0
ENGLAND,TRIUMPH,TR7,HARDTOP,2,4292,5100,0
JAPAN,DATSUN,B210 2 DOOR AUTO,SEDAN,4,2626,3139,4300
JAPAN,TOYOTA,COROLLA 4 DOOR DIX AUTO,SEDAN,4,2886,3339,35030
ITALY,ALFA ROMEO,2000 4 DOOR BERLINA,SEDAN,4,4915,5925,4800
ITALY,ALFA ROMEO,2000 GT VELOCE,COUPE,2,5660,6820,12400
ITALY,ALFA ROMEO,2000 SPI,2,25000,31500,0,13000
ITALY,MASERATI,DORA 2 DOOR,COUPE,2,25000,31500,0
GERMANY,AUDI,100 LS 2 DOOR AUTO,SEDAN,5,5063,5970,7800
GERMANY,BMW,2002 2 DOOR,SEDAN,5,5800,5940,8950

GERMANY,BMW,530I 4 DOOR,SEDAN,5,8300,9097,14000
GERMANY,BMW,530I 4 DOOR AUTO,SEDAN,5,8400,9495,1560
FRANCE,PEUGEOT,504 4 DOOR,SEDAN,5,4631,5610,0
```

To generate a synonym for the DFIX comma delimited data file, enter the following information on the Create Synonym panes of the Web Console or the Data Management Console:

1. In the Directory path field, enter the directory name containing the delimited flat file.
2. Enter the file name (for example, dfix_car).
3. Enter the file extension field (for example, .dat.)
4. Click *Select Files*.
5. On the second Create Synonym pane, select a file from the list of displayed data files and specify *comma*, as the separator, in the Delimiter field.
6. Click *Create Synonym*. The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: *All Synonyms Created Successfully*

7. From the message window, click *Applications* on the menu bar.
8. Open the *baseapp* application folder in the navigation pane and click the synonym–in this example, *dfix_car*.
9. Choose *Edit as Text* from the menu to view the generated Master File, then choose *Edit Access File as Text* to view the corresponding Access File.

Generated Master File:

```
FILENAME=CAR_DFIX, SUFFIX=DFIX    ,
 DATASET=directory/car_dfix.dat, $
  SEGMENT=CAR_DFIX, SEGTYPE=S0, $
    FIELDNAME=FIELD_1, USAGE=A7, ACTUAL=A7BV, $
    FIELDNAME=FIELD_2, USAGE=A10, ACTUAL=A10BV, $
    FIELDNAME=FIELD_3, USAGE=A23, ACTUAL=A23BV, $
    FIELDNAME=FIELD_4, USAGE=A11, ACTUAL=A11BV, $
    FIELDNAME=FIELD_5, USAGE=I1, ACTUAL=A1, $
    FIELDNAME=FIELD_6, USAGE=I5, ACTUAL=A5V, $
    FIELDNAME=FIELD_7, USAGE=I5, ACTUAL=A5V, $
    FIELDNAME=FIELD_8, USAGE=I5, ACTUAL=A5V, $
```

Note that the FILE declaration in the generated Master File includes the attribute:

```
SUFFIX=DFIX
```

Generated Access File:

```
SEGNAME=DFIX_CAR, DELIMITER=',', HEADER=NO,$
```

The delimiter consists of a single printable character.

Example: Sample DFIX Data File With Header and Enclosure

This sample file contains a header line and uses the enclosure character ".

```
"COUNTRY","CAR","MODEL","BODYTYPE","SEATS","DEALER_COST","RETAIL_COST","SALE
S"
"ENGLAND","JAGUAR","V12XKE AUTO","CONVERTIBLE",2,7427,8878,0
"ENGLAND","JAGUAR","XJ12L AUTO","SEDAN",5,11194,13491,12000
"ENGLAND","JENSEN","INTERCEPTOR III","SEDAN",4,14940,17850,0
"ENGLAND","TRIUMPH","TR7","HARDTOP",2,4292,5100,0
"FRANCE","PEUGEOT","504 4 DOOR","SEDAN",5,4631,5610,0
"ITALY","ALFA ROMEO","2000 4 DOOR BERLINA","SEDAN",4,4915,5925,4800
"ITALY","ALFA ROMEO","2000 GT VELOCE","COUPE",2,5660,6820,12400
"ITALY","ALFA ROMEO","2000 SPIDER VELOCE","ROADSTER",2,5660,6820,13000
"ITALY","MASERATI","DORA 2 DOOR","COUPE",2,25000,31500,0
"JAPAN","DATSUN","B210 2 DOOR AUTO","SEDAN",4,2626,3139,43000
"JAPAN","TOYOTA","COROLLA 4 DOOR DIX AUTO","SEDAN",4,2886,3339,3503
"GERMANY","AUDI","100 LS 2 DOOR AUTO","SEDAN",5,5063,5970,7800
"GERMANY","BMW","2002 2 DOOR","SEDAN",5,5800,5940,8950
"GERMANY","BMW","2002 2 DOOR AUTO","SEDAN",4,6000,6355,8900
"GERMANY","BMW","3.0 SI 4 DOOR","SEDAN",5,10000,13752,14000
"GERMANY","BMW","3.0 SI 4 DOOR AUTO","SEDAN",5,11000,14123,18940
"GERMANY","BMW","530I 4 DOOR","SEDAN",5,8300,9097,14000
"GERMANY","BMW","530I 4 DOOR AUTO","SEDAN",5,8400,9495,15600
```

On the Synonym Creation panes, specify the *Delimiter* character as comma (,), the *Enclosure* character as double quotation marks ("), and check the *Header* box to use the names in the header line as field names (columns) in the Master File.

Generated Master File:

```
FILENAME=CAR_CSV, SUFFIX=DFIX    ,
 DATASET=directory/car_csv.csv, $
  SEGMENT=CAR_CSV, SEGTYPE=S0, $
    FIELDNAME=COUNTRY, ALIAS=COUNTRY, USAGE=A7, ACTUAL=A7BV, $
    FIELDNAME=CAR, ALIAS=CAR, USAGE=A10, ACTUAL=A10BV, $
    FIELDNAME=MODEL, ALIAS=MODEL, USAGE=A23, ACTUAL=A23BV, $
    FIELDNAME=BODYTYPE, ALIAS=BODYTYPE, USAGE=A11, ACTUAL=A11BV, $
    FIELDNAME=SEATS, ALIAS=SEATS, USAGE=I1, ACTUAL=A1, $
    FIELDNAME=DEALER_COST, ALIAS=DEALER_COST, USAGE=I5, ACTUAL=A5V, $
    FIELDNAME=RETAIL_COST, ALIAS=RETAIL_COST, USAGE=I5, ACTUAL=A5V, $
    FIELDNAME=SALES, ALIAS=SALES, USAGE=I5, ACTUAL=A5V, $
```

The Delimiter, Enclosure, and Header entries are reflected in the Access File.

Generated Access File:

```
SEGNAME=CAR_CSV, DELIMITER=',', ENCLOSURE=", HEADER=YES, $
```

Reference: Usage and Actual Formats for Delimiters

Prior to Version 7 Release 6.1, server delimiter characters were identified by a field description in the Master File instead of by the DELIMITER parameter of the Access File.

Therefore, older synonyms may use this syntax with a FIELDNAME of DELIMITER, an ALIAS of the delimiter itself, and with USAGE and ACTUAL values as described in the following chart.

For example:

```
FIELDNAME=DELIMITER, ALIAS=',', USAGE=A1, ACTUAL=A1, $
```

USAGE and ACTUAL formats are determined as follows:

Type of delimiter	USAGE	ACTUAL
Printable characters	A*n* where *n* is the number of characters	A*n* where *n* is the number of characters
Non-printable character such as Tab	I4	I1
Group (combination of printable and non-printable characters, or multiple non-printable characters)	Sum of the individual USAGE lengths	Sum of the individual ACTUAL lengths

Reference: Updating Delimited Files

You can update Delimited Flat files using the MODIFY facility. The following delimiter characters are respected:

TAB

A tab character. This is the default.

a

A character string, for example ~.

0x*nn*

A hex code. For example, 0x44 (a comma), or 0x0D0A (a return and a linefeed). The hex code uses ASCII for Windows or UNIX systems and EBCDIC for IBM Mainframes.

Delimited files have been added as a target type for DataMigrator flows.

Chapter 28

Using the Adapter for Git

The adapter for Git allows a vast range of workflow possibilities for projects and teams. The two most commonly used paradigms are Centralized Workflow and Integration-manager Workflow.

In this chapter:

Introducing the Adapter for Git

Git is a free, open source Distributed Version Control System (DVCS), that allows multiple developers to work on the same remote repository, while having a full copy of the remote repository locally.

Preparing the Git Environment

The following jar files are needed to use the adapter for Git. All of the files should be downloaded and saved to your path, since you will be using them during the configuration process in the IBI_CLASSPATH box. The list below includes the name of the file, along with the direct link to its location:

slf4j-api-1.7.25.jar:

https://mvnrepository.com/artifact/org.slf4j/slf4j-api/1.7.25

slf4j-simple-1.6.2.jar:

https://mvnrepository.com/artifact/org.slf4j/slf4j-simple/1.6.2

bcpg-jdk15on-1.60.jar:

https://mvnrepository.com/artifact/org.bouncycastle/bcpg-jdk15on/1.60

bcprov-jdk15on-1.60.jar:

https://mvnrepository.com/artifact/org.bouncycastle/bcprov-jdk15on/1.60

jsch-0.1.54.jar:

https://mvnrepository.com/artifact/com.jcraft/jsch/0.1.54

org.eclipse.jgit-5.3.0.201903130848-r.jar:

https://mvnrepository.com/artifact/org.eclipse.jgit/org.eclipse.jgit/5.3.0.201903130848-r

commons-io-2.6.jar:

https://mvnrepository.com/artifact/commons-io/commons-io/2.6

Configuring the Adapter for Git

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Adapter for Git

You can configure the adapter from either the Web Console or the Data Management Console.

Note: On Windows, the Environmental Variable PATH should include the directory where the Git utilities are installed. For example, C:\Program Files\Git\usr\bin.

1. From the Web Console Applications page, click *Get Data*.

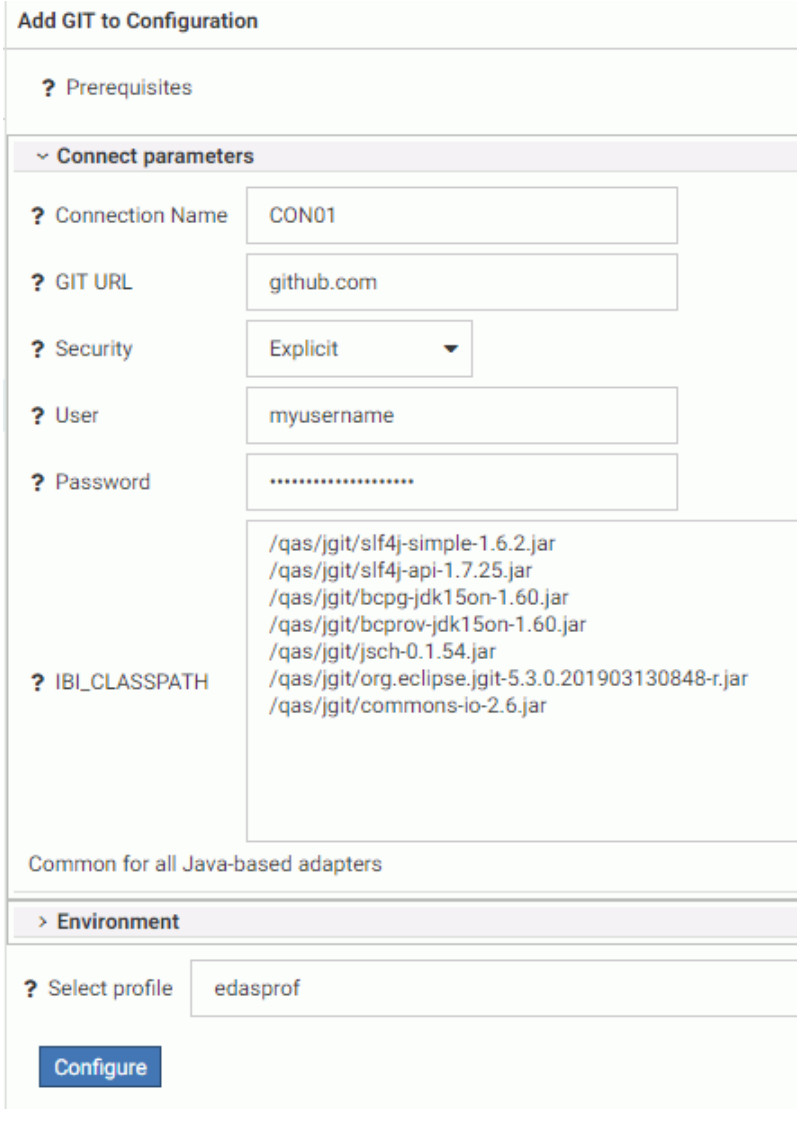
   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click *Git* and click *Configure*.
5. Enter the connection name that is used in the WebFOCUS application.
6. In the GIT URL box, type the URL used to connect to your Git repository.
7. Select *Explicit* as the security type and type your user ID and password.
8. In the IBI_CLASSPATH box, enter the jar file names using the following format: *full_path_GIT_jar_names*.

The following image shows an example of the configuration settings used:



9. Select *edasprof* from the Select profile drop-down menu to add this connection for all users, or select a user profile.
10. Click *Configure*.
11. Click *Test* once the initial configuration is complete. You should see a list of data sources on your server.

To start using the adapter, you must either use the INIT command to create a new repository, or use the CLONE command on an existing one.

Reference: Adapter for Git Configuration Settings

The Adapter for Git is under the SQL group folder.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Git URL

The full computer name or URL for the site where the remote repositories are located.

Note: A remote repository can be located on a remote network location or on your local file system.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

The user ID used to connect to the Git server.

Password

The password used to connect to the Git server.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. This value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions when setting values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar). When editing the file manually, you must maintain the colon delimiter.

For the Git adapter, the full path GIT jar file names are entered.

Select profile

Select a profile from the drop-down menu to store the configured connection.

Chapter 29

Using the Adapter for Google Analytics

This section describes how to configure the Google Analytics Adapter.

In this chapter:

Google Analytics Adapter Overview

The Google Analytics Adapter is used to report against the information residing in the Google Analytics environment. Metrics, such as Page Views and Users, can be analyzed by various dimensions (for example, Country and City).

You can configure the Google Analytics Adapter using the WebFOCUS Reporting Server Web Console. The adapter requires a connection, which stores the access token. A valid Google Analytics access token is required to issue Google Analytics API calls. This token is associated with a Google Analytics application and a specific Google Analytics user.

Creating a Google Project

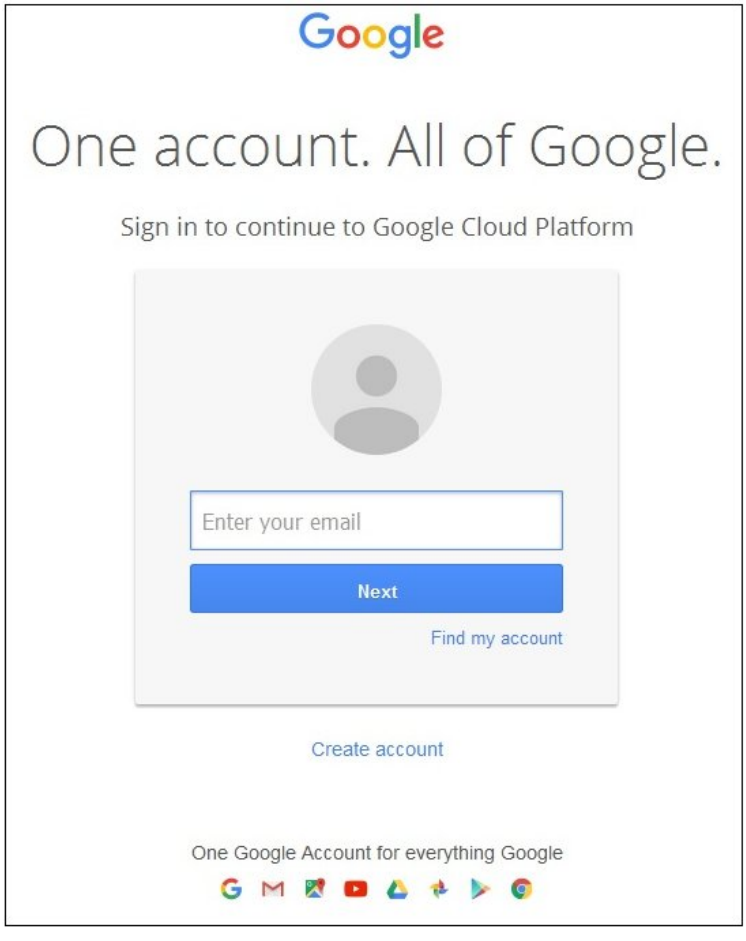
A Google project must be available before you can configure the Google Analytics Adapter.

Procedure: How to Create a Google Project

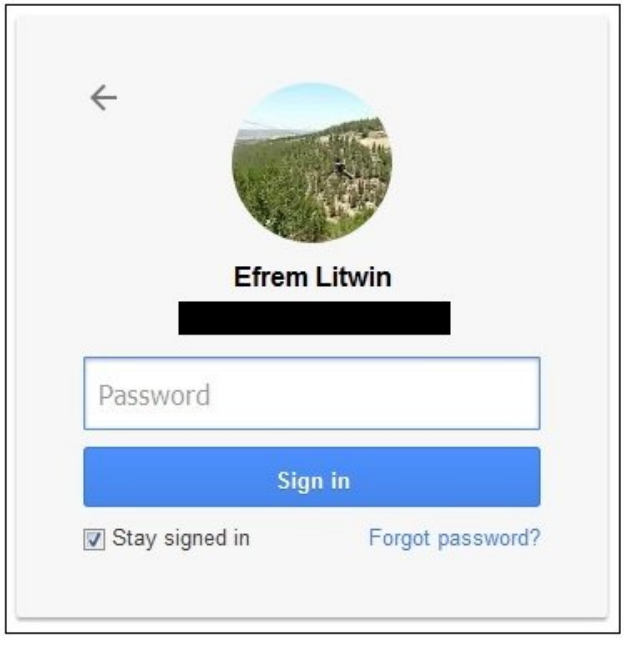
1. Enter the following URL in a web browser:

   `https://console.developers.google.com/project`

If you are not already signed into Google, a Sign in dialog for the Google Cloud Platform opens, as shown in the following image.

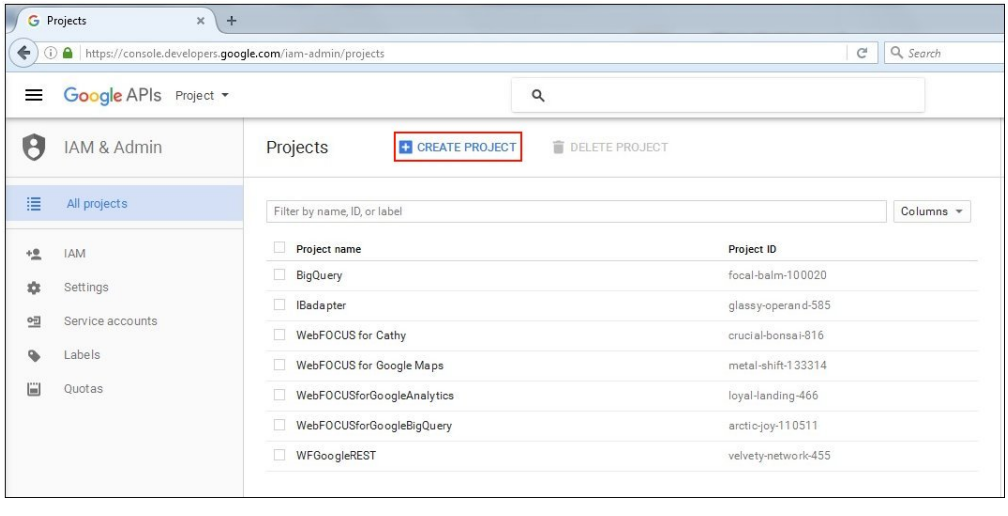


2. Enter an email address for the Google account that has administrative rights to the Google Analytics environment, and then click *Next*.



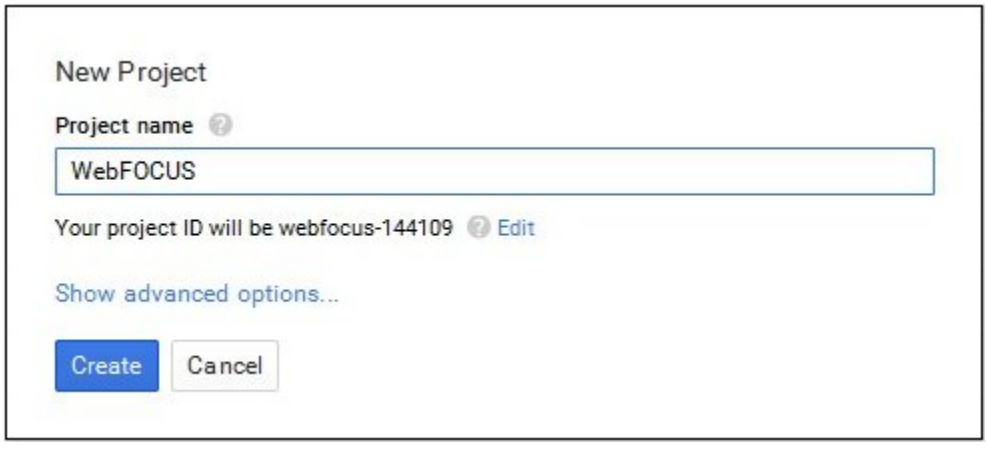
3. Enter a valid password for the Google account, and then click *Sign In*.

   The Projects screen opens, as shown in the following image.



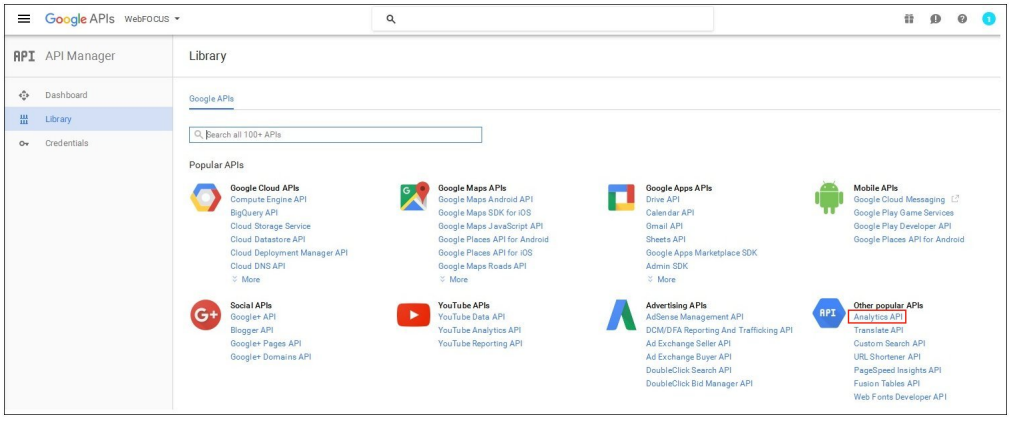
4. Click *CREATE PROJECT*.

The New Project screen opens, as shown in the following image.



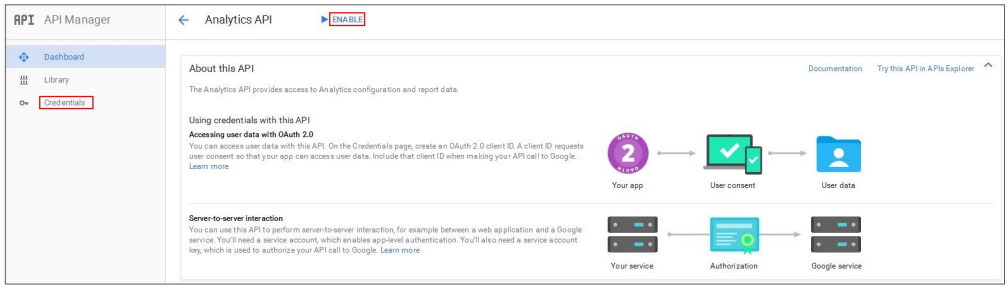
5. Enter a name for your new project and then click *Create*.

   The Library screen opens, as shown in the following image.



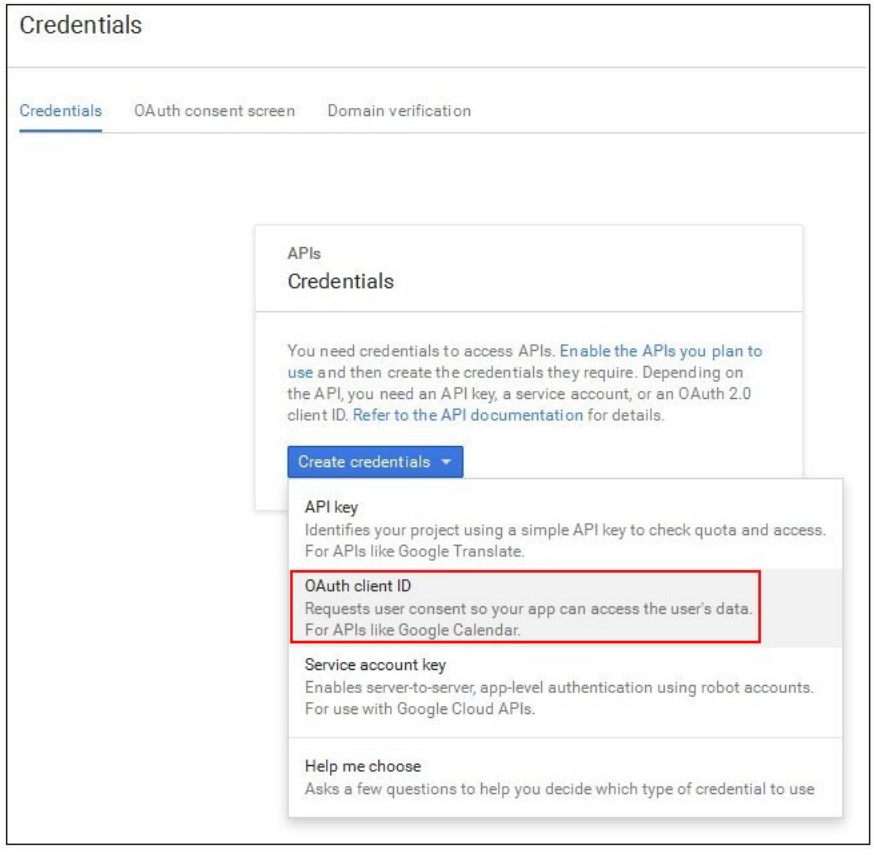
6. Click *Analytics API* under the *Other popular APIs* group.

The Analytics API screen opens, as shown in the following image.



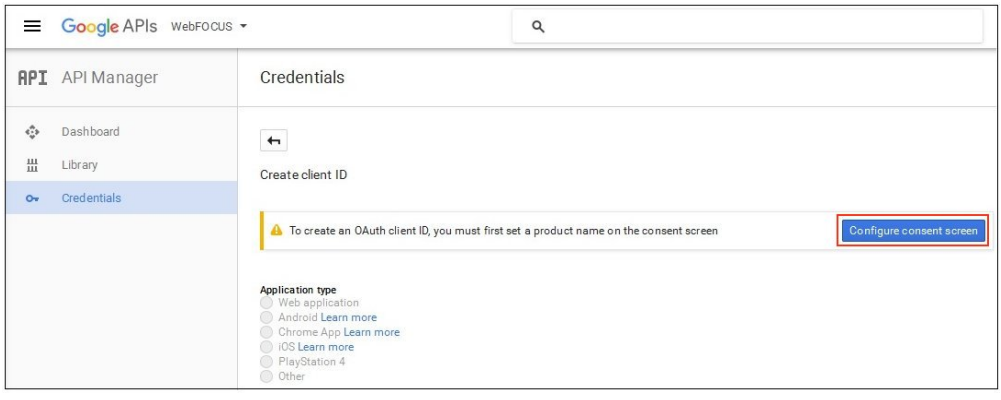
7. Click *ENABLE*.
8. Click *Credentials* in the left pane.

   The Credentials screen opens, as shown in the following image.



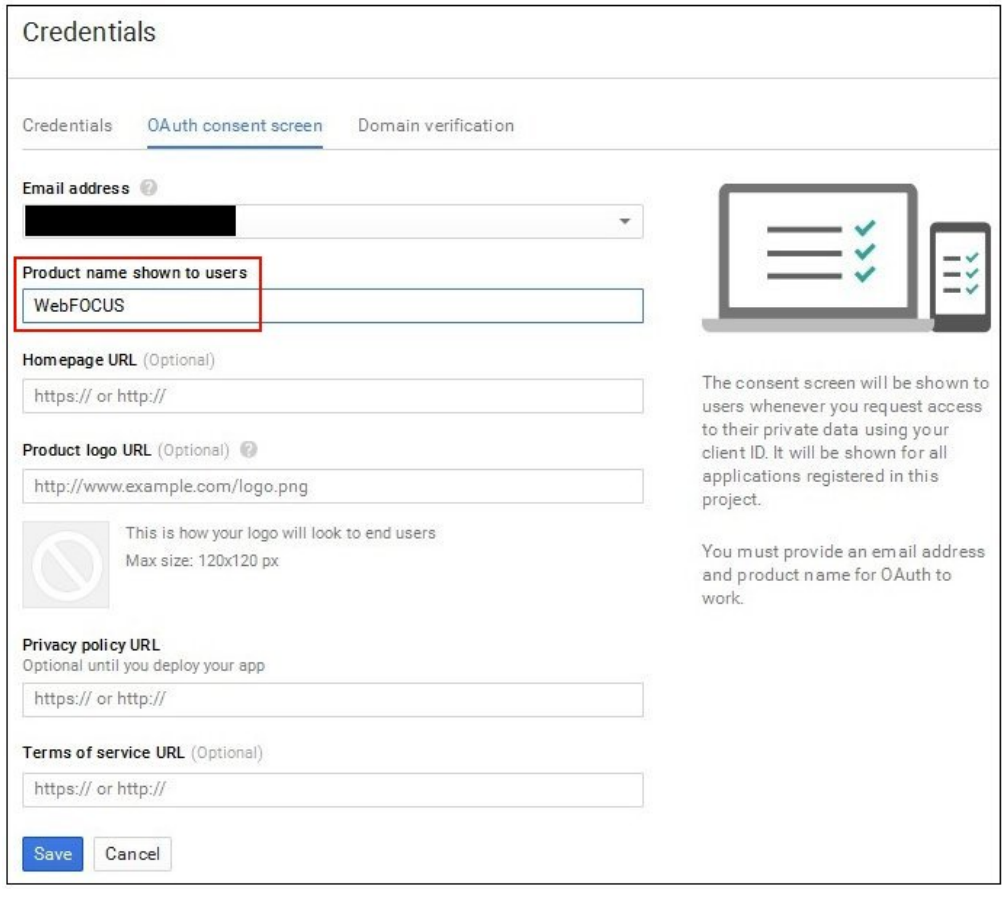
9. Click the *Create credentials* drop-down list and select *OAuth client ID*.

   The Create client ID screen opens, as shown in the following image.



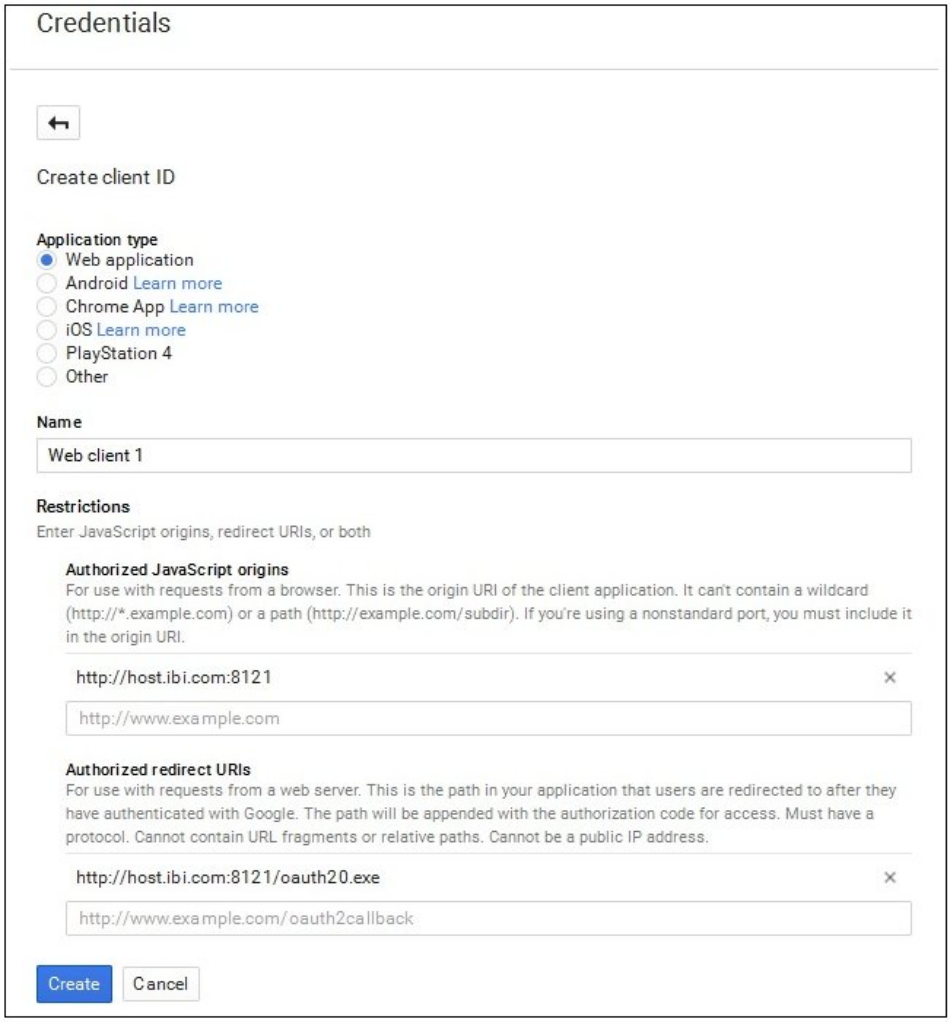
10. Click *Configure consent screen*.

The OAuth consent screen opens, as shown in the following image.



11. Enter a value in the *Product name shown to users* field and click *Save*.

The Application type screen opens, as shown in the following image.



12. Perform the following steps:
    a. Select *Web application* from the list of application types.
    b. Enter the host name and port used to access the WebFOCUS Reporting Server Web Console in the *Authorized JavaScript origins* field.

       For example:

       `http://host.ibi.com:8121`

If the WebFOCUS Reporting Server is installed as a standalone server, then `http://localhost` should be specified as the value in the *Authorized JavaScript origins* field.

c. Enter the host name and port used to access the WebFOCUS Reporting Server Web Console with oauth20.exe in the *Authorized redirect URIs* field.

For example:

```
http://host.ibi.com:8121/oauth20.exe
```

If the WebFOCUS Reporting Server is installed as a standalone server, then `http://localhost/oauth20.exe` should be specified as the value in the *Authorized redirect URIs* field.

13. Click *Create*.

The OAuth client screen opens, which displays your *client ID* and *client secret* values, as shown in the following image.

The *client ID* and *client secret* values are required to configure the Google Analytics Adapter.

14. Click *OK*.

You are now ready to obtain the Web Profile ID for a website within the Google Analytics environment.

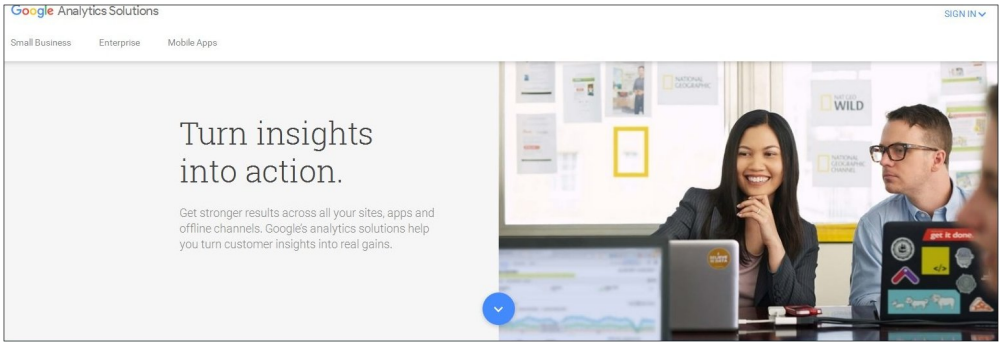
Obtaining the Web Profile ID

This section describes how to obtain the Web Profile ID for a website within the Google Analytics environment. The Web Profile ID is required to configure the Google Analytics Adapter.

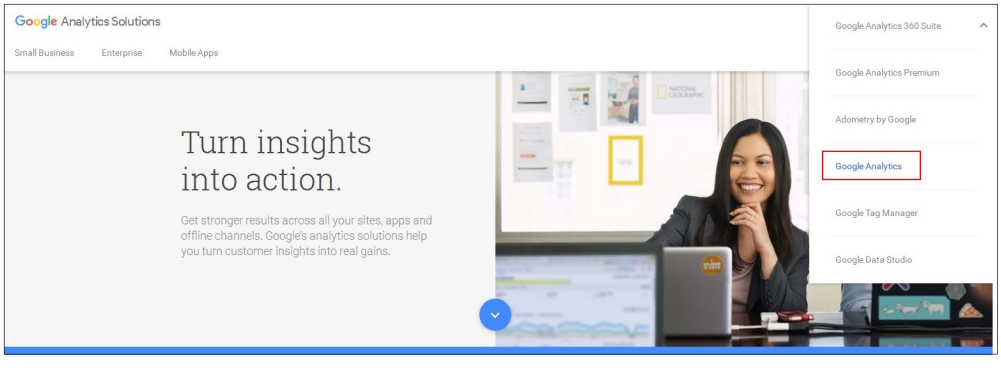
Procedure: How to Obtain the Web Profile ID

1. Enter the following URL in a web browser:

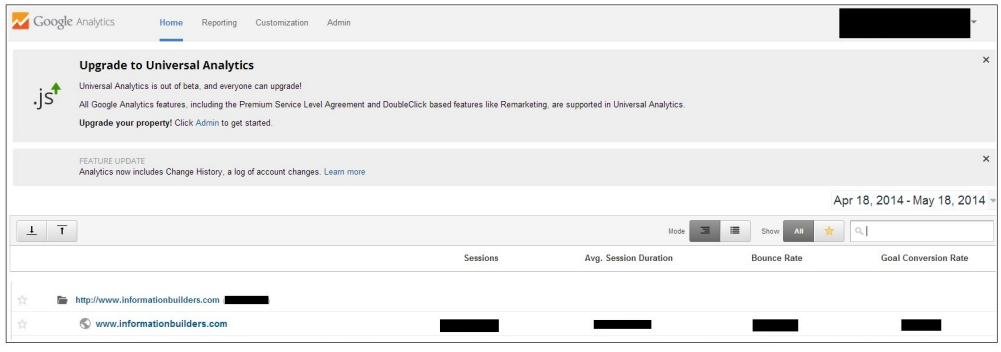
   `https://www.google.com/analytics`



2. Click *SIGN IN* in the upper-right corner of the page.
3. Select *Google Analytics*, as shown in the following image.

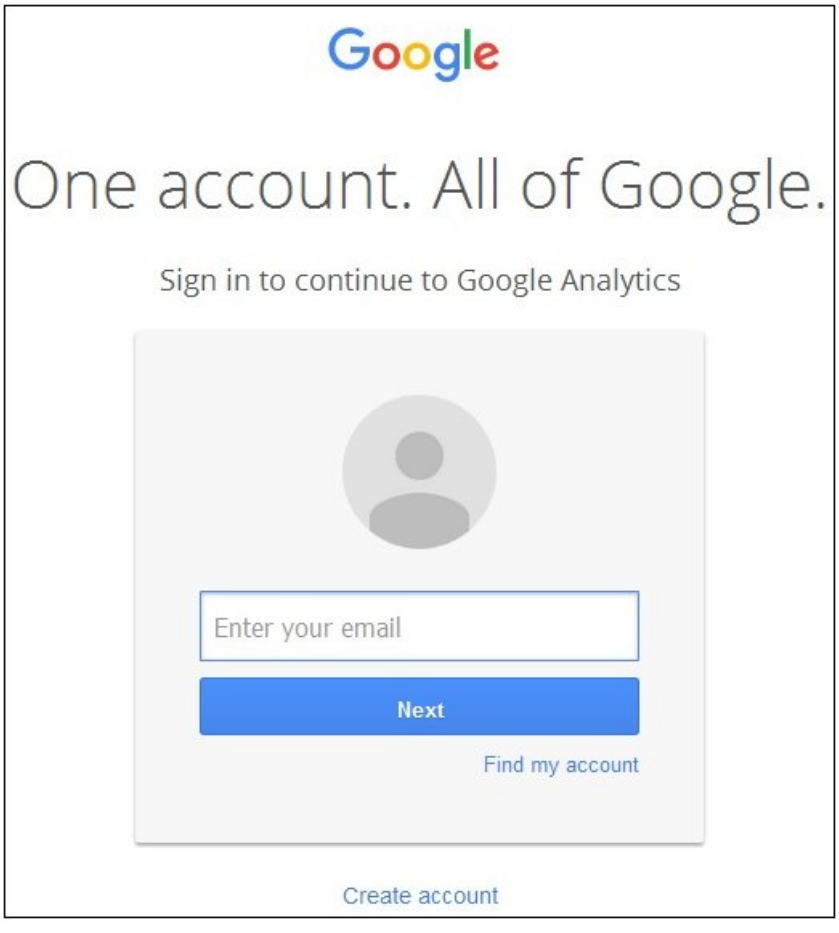


If you are already signed in to Google, then the Google Analytics page which lists the configured websites opens, as shown in the following image.

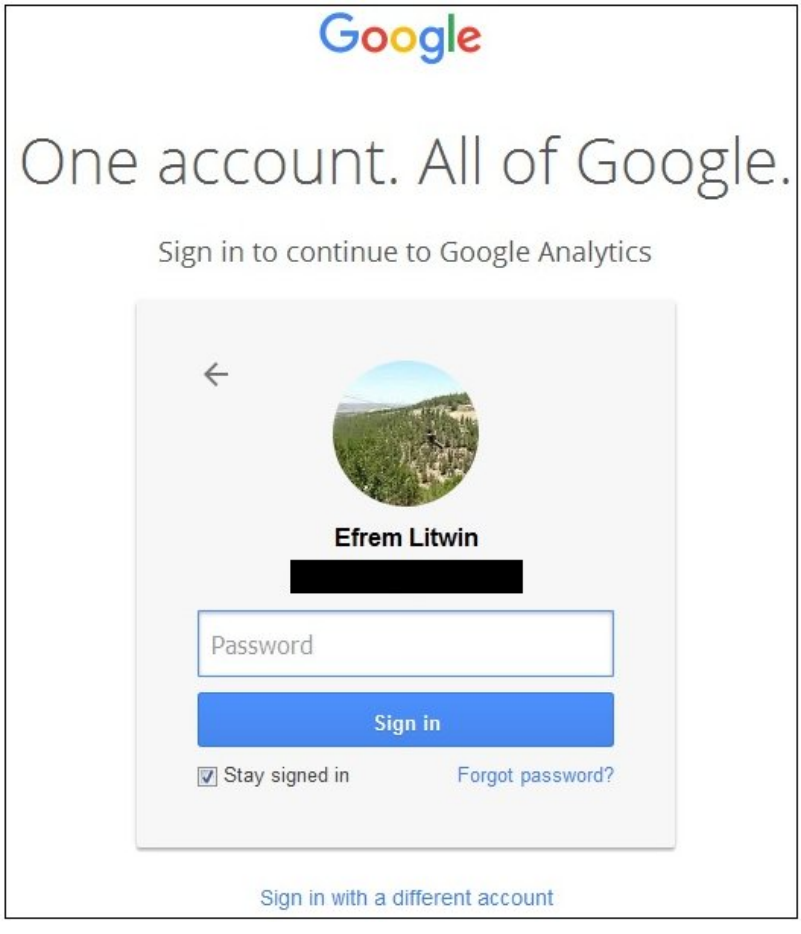


If you are not already signed in to Google Analytics, then click the *SIGN IN* link in the upper-right corner of the page.

A Sign in to Google Analytics page opens, as shown in the following image.



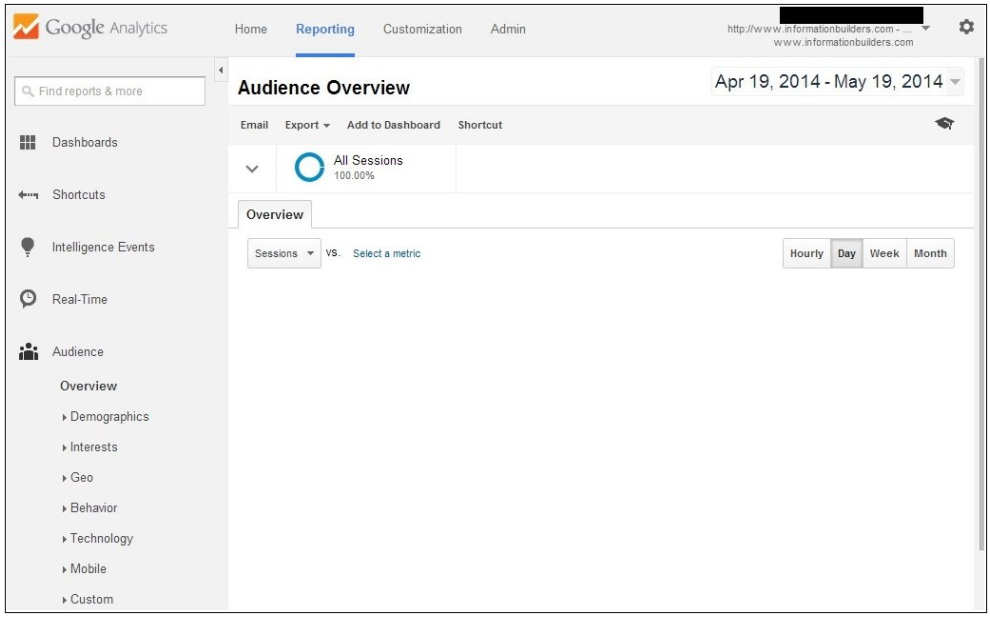
Enter an email address for the Google account that has administrative rights to the Google Analytics environment, and then click *Next*.



Enter a valid password for the Google account, and then click *Sign In*.

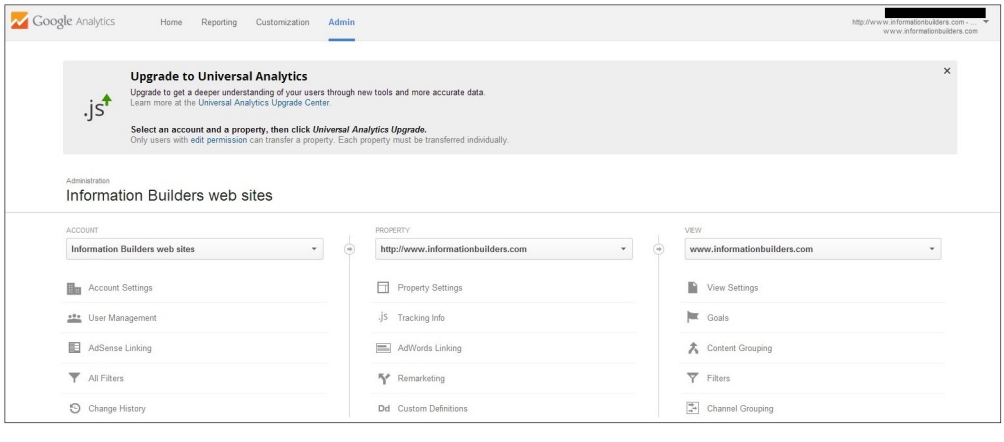
4. Click the link to the website that will be used during the configuration of the Google Analytics Adapter.

The Google Analytics Reporting page for the selected website opens, as shown in the following image.



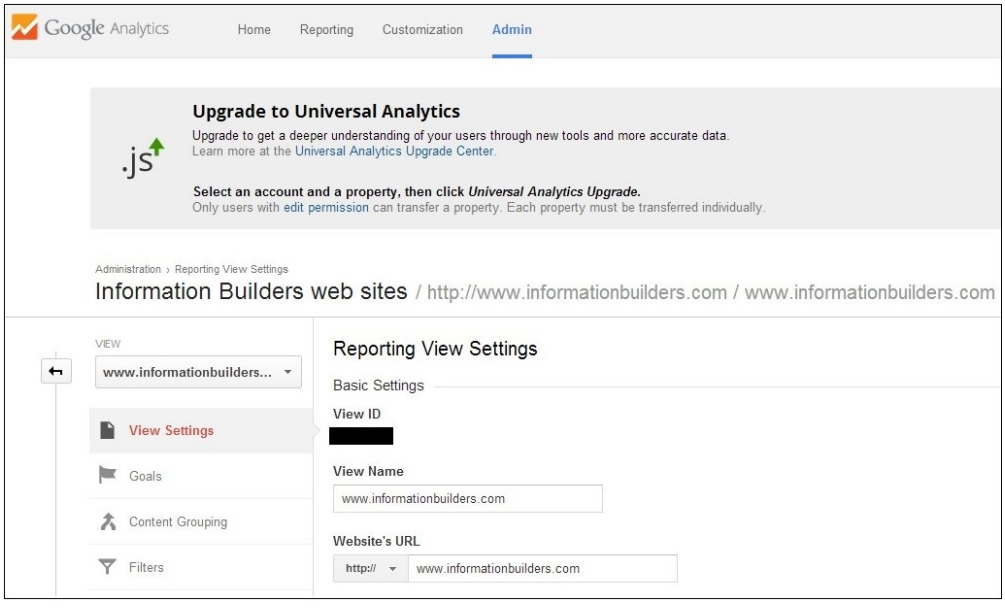
5. Click the *Admin* link at the top of the page.

   The Google Analytics Admin page for the selected website opens, as shown in the following image.



6. Click the *View Settings* link, which is located in the View column.

The Google Analytics Reporting View Settings page for the selected website opens, as shown in the following image.



The View ID value is required to configure the Google Analytics Adapter.

Configuring the Google Analytics Adapter

This section describes how to configure the Google Analytics Adapter.

Procedure: How to Configure the Google Analytics Adapter

1. Clear the cookies from the web browser that will be used to start the WebFOCUS Reporting Server Web Console.
2. Access the WebFOCUS Reporting Server Web Console using the host name and port that you specified in the AUTHORIZED JAVASCRIPT ORIGINS field of the Google project.

   For example:

   `http://host.ibi.com:8121`

   For more information, see *How to Create a Google Project* on page 777.
3.
4. From the Web Console Applications page, click *Get Data*.

or

From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

5. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
6. Right-click the *Google Analytics* node and select *Configure*.

   The Add Google Analytics to Configuration pane opens, as shown in the following image.

7. Enter the values for the Client ID and Client Secret as defined by the Client ID and Client secret respectively in the Google project.

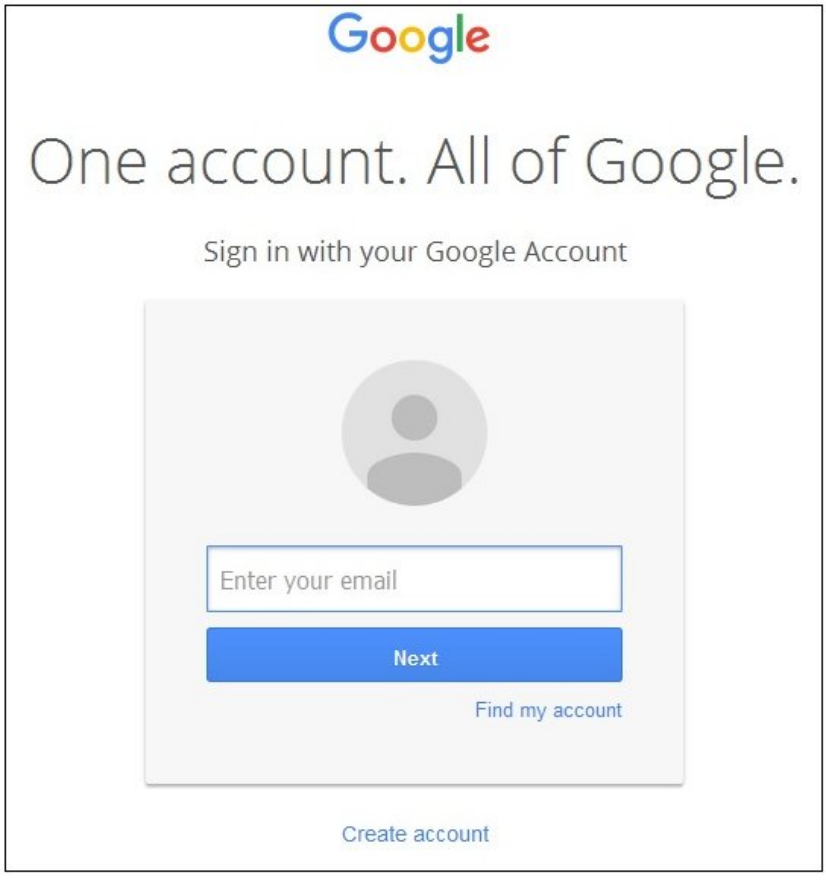
   For more information, see *How to Create a Google Project* on page 777.
8. Enter the value for the Web Profile ID as defined by the View ID in the Google Analytics Reporting View Settings for the selected website.

   This value is prefixed by *ga*. For example:

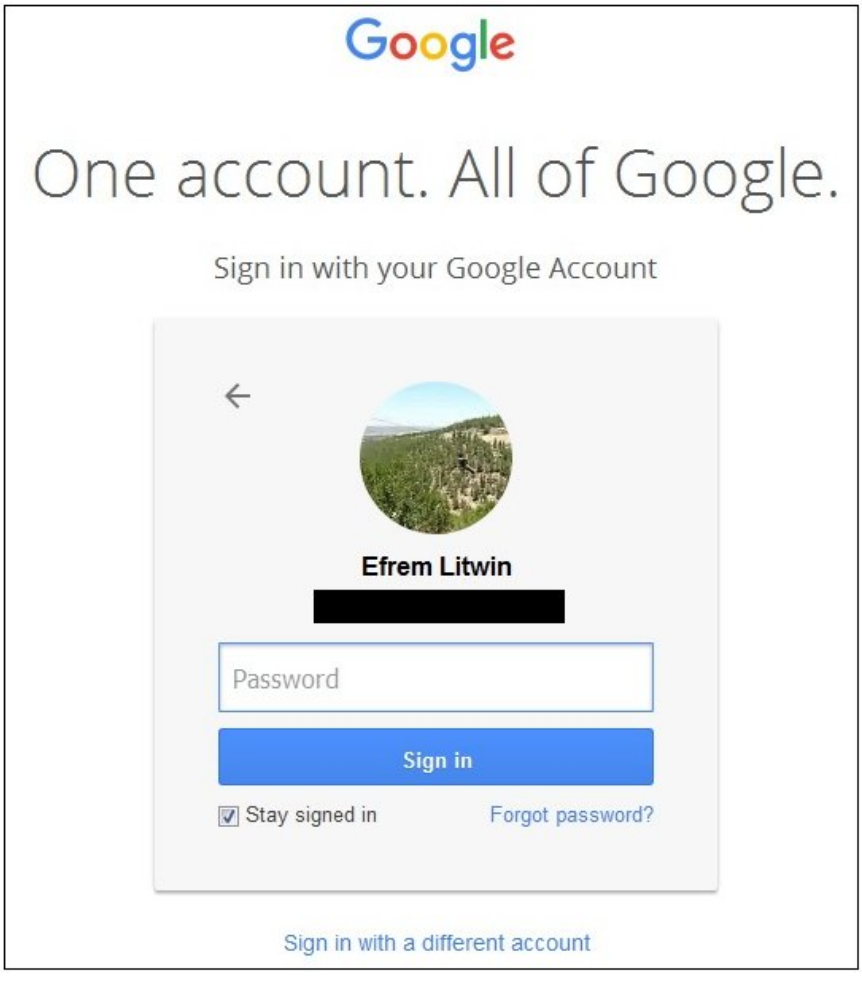
   ```
   ga:87878787
   ```

   For more information, see *How to Obtain the Web Profile ID* on page 786.
9. Click the *Get Access Token* link.

A Google Sign In page opens, as shown in the following image.

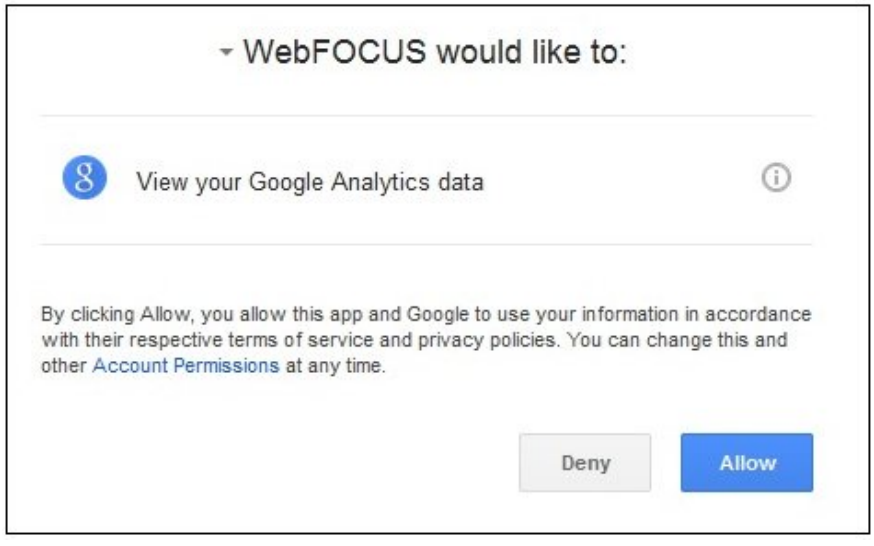


10. Enter an email address for the Google account that has administrative rights to the Google Analytics environment, and then click *Next*.



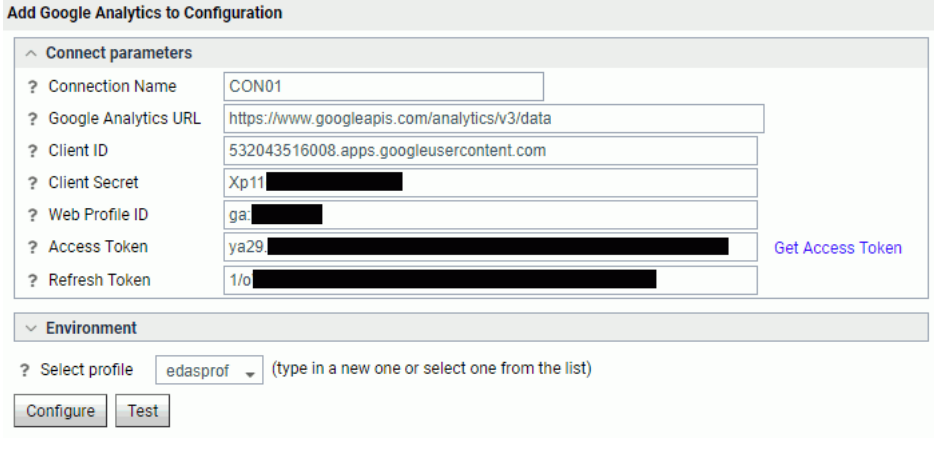
11. Enter a valid password for the Google account, and then click *Sign In*.

The View your Google Analytics data consent screen opens, as shown in the following image.



12. Click *Allow*.

    You are returned to the Add Google Analytics to Configuration pane, where the Access Token field and Refresh Token field are now populated, as shown in the following image.



13. Click *Configure*.

The Google Analytics Adapter is added to the configured Adapters list in the navigation pane.

Reference: Connection Attributes for Google Analytics

The following list describes the connection attributes for the Google Analytics Adapter.

Connection Name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Google Analytics URL

The URL of the Google Analytics API request. The default value is:

```
https://www.googleapis.com/analytics/v3/data
```

Client ID

The value that identifies your application to Google Analytics.

Obtain this value using the following steps:

1. Go to:

   ```
   https://cloud.google.com/console/project
   ```

2. Click on the Project Name for the Google Analytics Adapter application that was previously created.
3. Click *APIs & auth* in the left pane.
4. Click *Credentials* in the left pane.
5. Use Client ID in the Client ID for web application section.

Client Secret

The value which identifies your application to Google Analytics. This value is used in conjunction with Client ID.

Obtain this value using the following steps:

1. Go to:

   ```
   https://cloud.google.com/console/project
   ```

2. Click on the Project Name for the Google Analytics Adapter application that was previously created.
3. Click *APIs & auth* in the left pane.

4. Click *Credentials* in the left pane.
5. Use Client secret in the Client ID for web application section.

Web Profile ID

The ID that identifies the view (profile) for a Google Analytics account.

Obtain this value using the following steps:

1. Go to:

   ```
   http://www.google.com/analytics
   ```

2. Sign in with Google credentials that have administrative rights to Google Analytics.
3. Click on the website that is to be analyzed (for example, www.informationbuilders).
4. Click *Admin* in the upper-right corner of the screen.
5. Click *View Settings*.
6. Look for View ID under Basic Settings.

   This value is prefixed by *ga*. For example:

   ```
   ga:87878787
   ```

Access Token

The value that identifies the user your application is acting on behalf. Click the *Get Access Token* link to obtain this token and the Refresh Token.

In order for the Get Access Token to complete successfully, the host name used to access the WebFOCUS Reporting Server Web Console must match the host name specified for the Redirect URI in the Google Analytics application.

A Google sign-on screen opens if you are not already logged into a Google account.

A Consent screen opens. Click *Allow Access*.

If an issue arises when obtaining the Access and Refresh Tokens, clear your browser cache, including cookies.

Refresh Token

The Access Token has a very short lifespan. The Refresh Token is used to obtain a new Access Token during run time.

Select profile

Select a profile from the drop-down list to indicate the level of profile in which to store the connection attributes. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), select *New Profile* from the drop-down list and enter a name in the Profile Name field (the extension is added automatically).

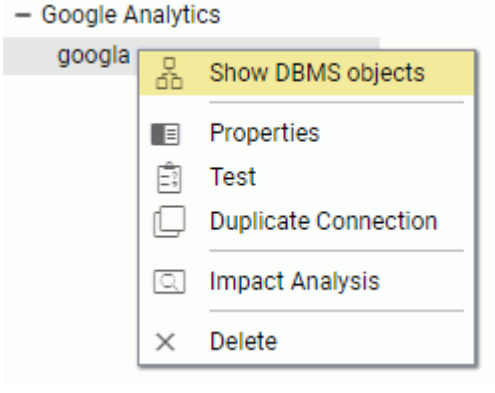
Store the connection attributes in the server profile (edasprof).

Creating Metadata for the Google Analytics Adapter

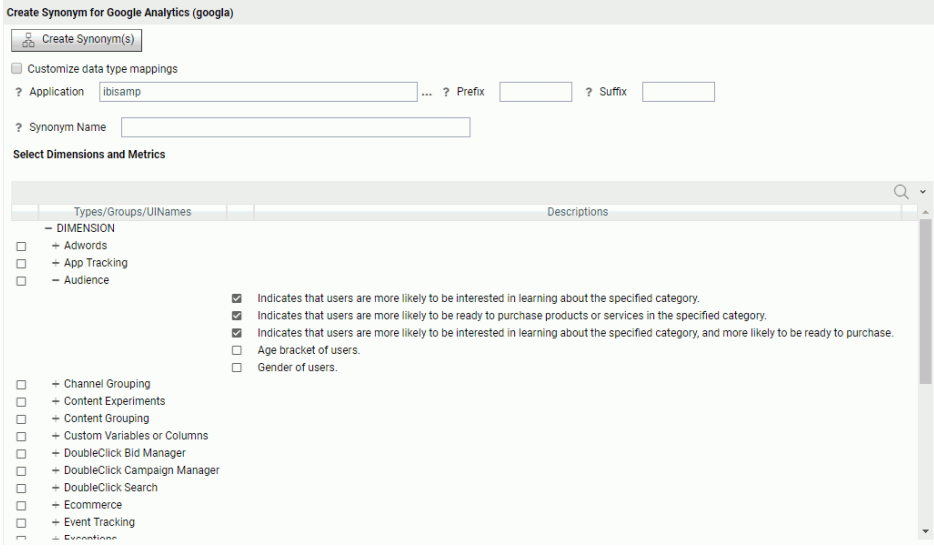
Create Synonym for the Google Analytics Adapter creates the metadata used for WebFOCUS reporting.

Procedure: How to Create Metadata

1. From the WebFOCUS Reporting Server Web Console, expand the *Adapters* folder, *Configured* folder, and then the *Google Analytics* folder.
2. Right-click the configured connection for the Google Analytics Adapter (for example, GoogleAnalytics) and select *Show DBMS objects* from the context menu, as shown in the following image.



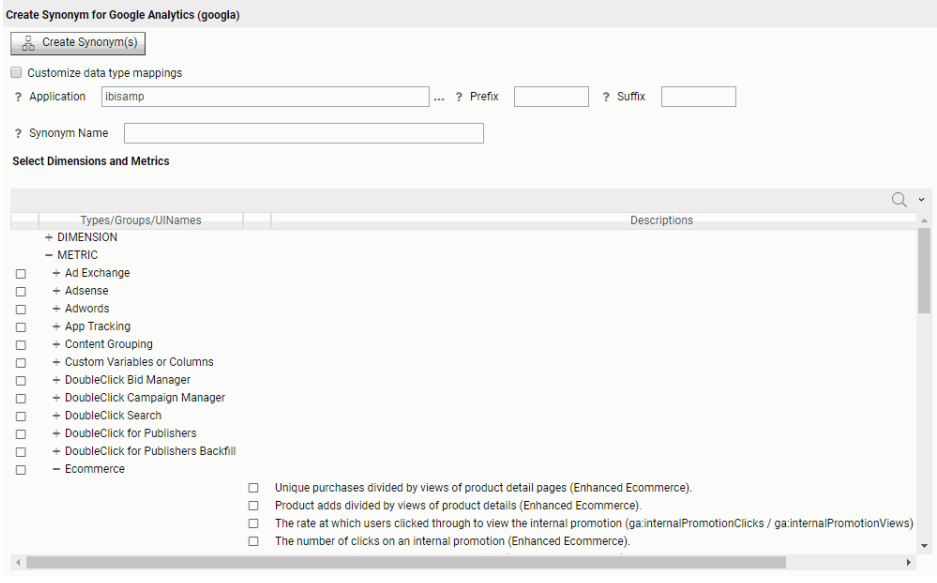
The Create Synonym for Google Analytics pane opens, as shown in the following image.



3. Enter a specific application in the Application field or click the ellipsis button to the right of the field to select an application where the metadata is to be stored.
4. Enter a Synonym Name that will be used to store the metadata.
5. Expand the *Dimensions* tree and select the dimensions that will be used for analysis.

   Note: Currently, Google Analytics only support 7 dimensions for a synonym. Google might increase this number sometime in the future.

Scroll down within the *Select Dimensions and Metrics* matrix and expand the *Metric* tree, as shown in the following image.



6. Select the metrics that will be used for analysis.

   Note: Currently, Google Analytics only support 10 metrics for a synonym. Google might increase this number sometime in the future.

7. Click *Create Synonym(s) and Examples*.

   The Create Synonym for Google Analytics Status pane opens and indicates that the synonym was created successfully.

Chapter 30

Using the Adapter for Google BigQuery

This section describes how to configure the Google BigQuery Adapter.

In this chapter:

Google BigQuery Adapter Overview

The Google BigQuery Adapter is used to load data into the Google BigQuery environment and report against the information that is residing in the Google BigQuery environment.

You can configure the Google BigQuery Adapter using the WebFOCUS Reporting Server Web Console. The adapter requires a connection, which stores the access token. A valid Google BigQuery access token is required to issue Google BigQuery API calls. This token is associated with a Google BigQuery application and a specific Google BigQuery user.

Creating a Google BigQuery Project

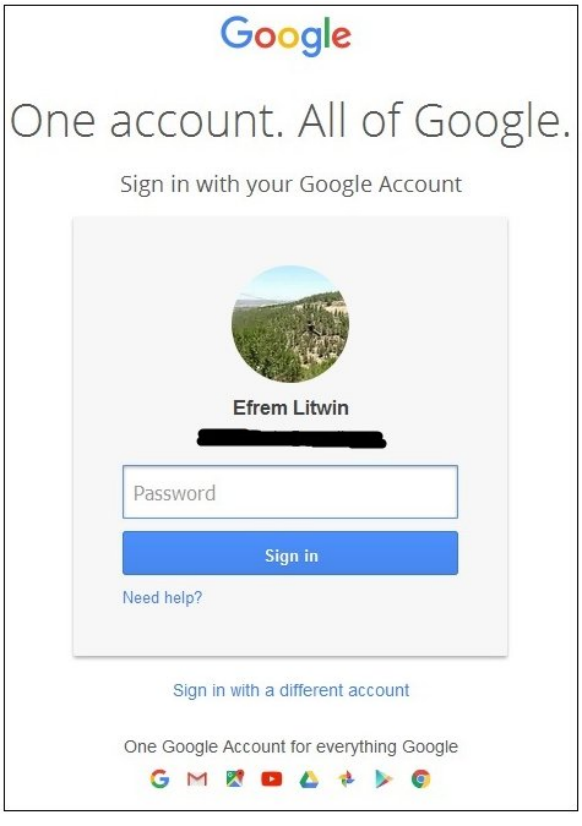
A Google project must be available before you can configure the Google BigQuery Adapter.

Procedure: How to Create a Google Project

1. Enter the following URL in a web browser:

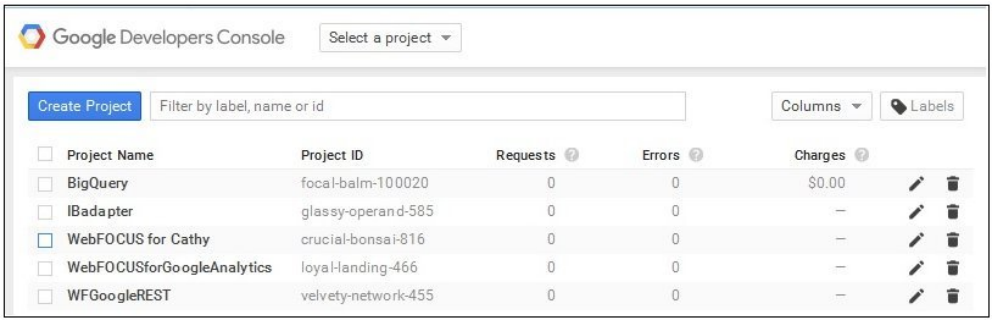
   `https://console.developers.google.com/project`

If you are not already signed into a Google account, a Sign in dialog for the Google Developers Console opens, as shown in the following image.



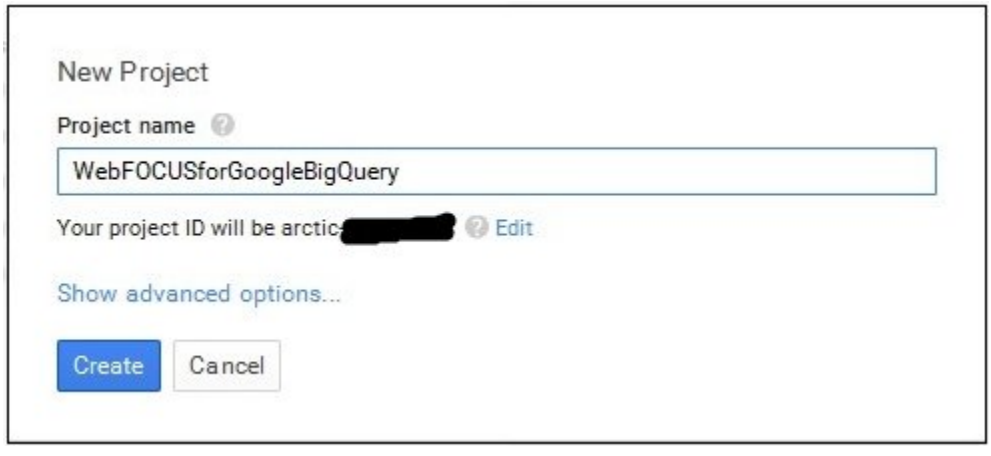
2. Enter the Google sign in credentials using an account that has administrative rights to the Google BigQuery environment, and then click *Sign In*.

   The Google Developers Console screen opens, as shown in the following image.



3. Click *CREATE PROJECT*.

   The New Project screen opens, as shown in the following image.



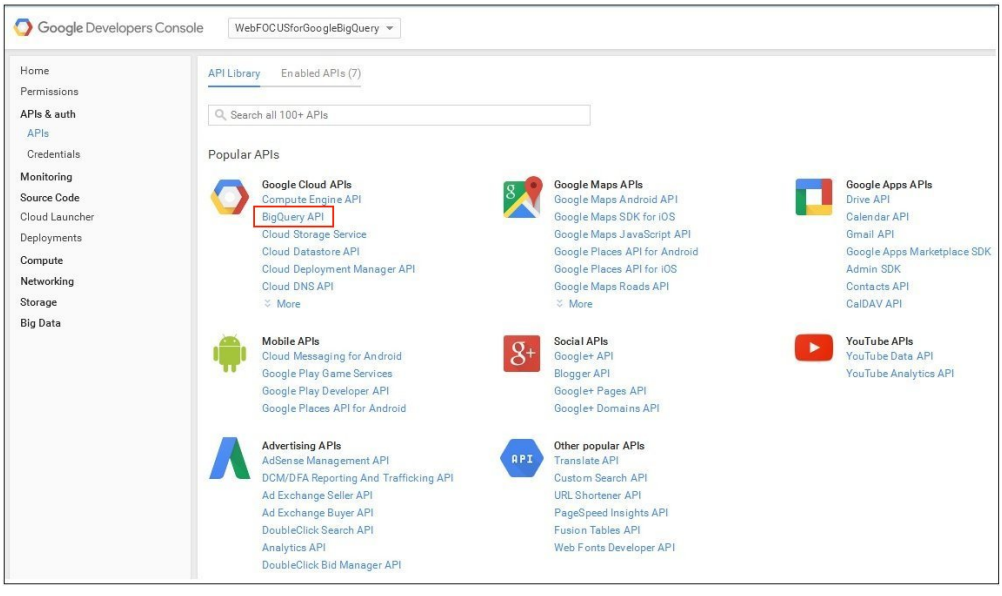
4. Enter a project name and then click *Create*.

   The page that is used to configure the project opens, as shown in the following image.

   Note: The ID will be used in the Google BigQuery Adapter configuration.

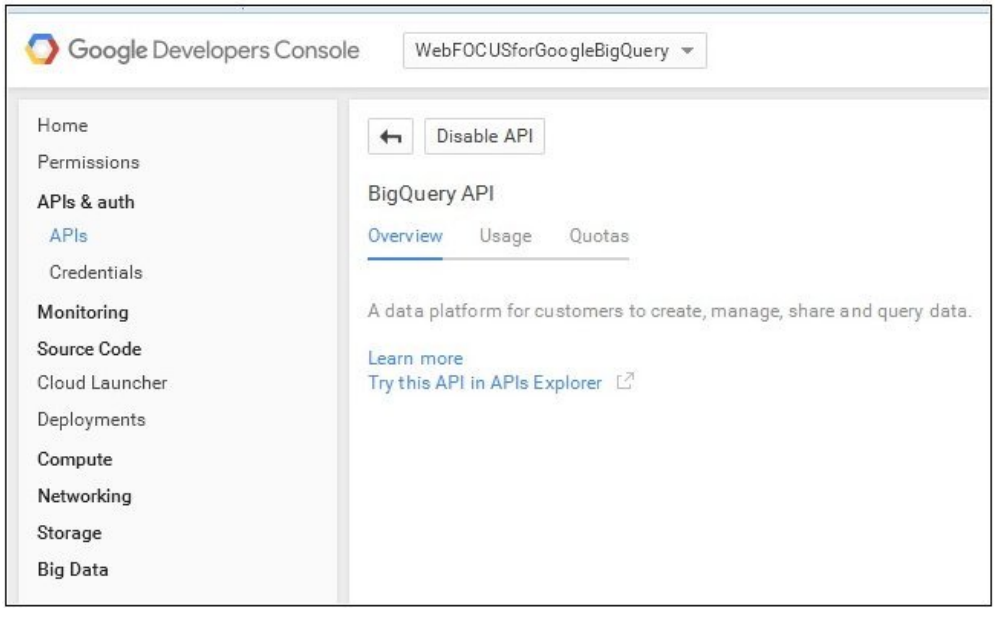
5. Click *APIs & auth* in the left pane.
6. Click *APIs* in the left pane.

The API Library screen opens, as shown in the following image.



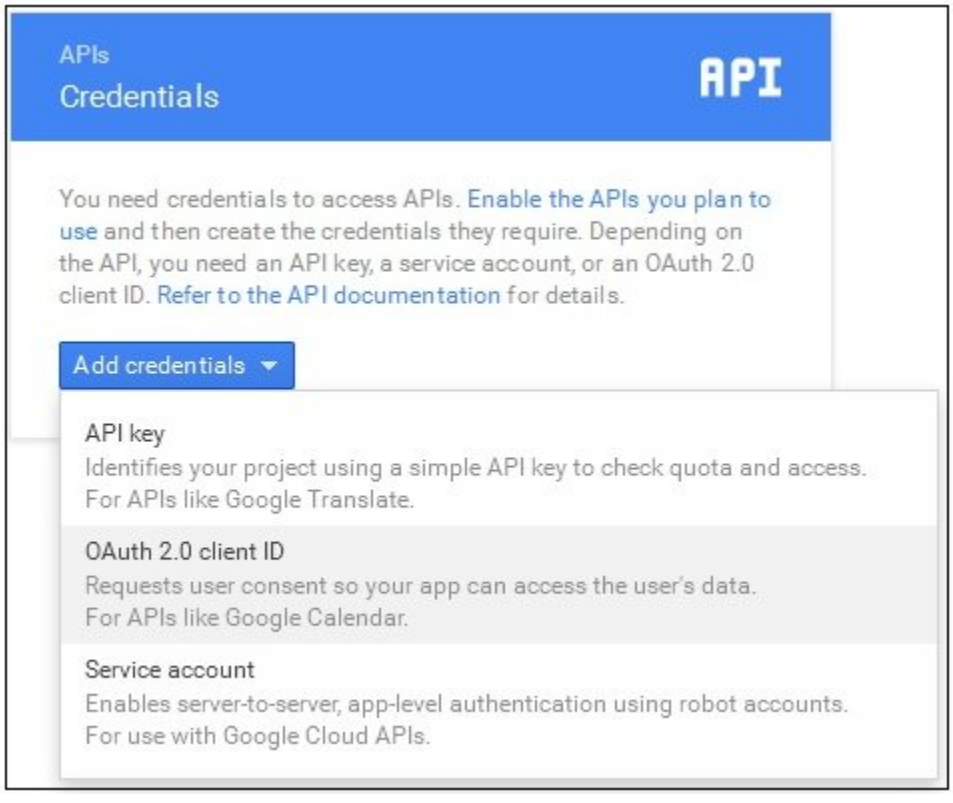
7. Click *BigQuery API*.

The BigQuery API is enabled, as shown in the following image.



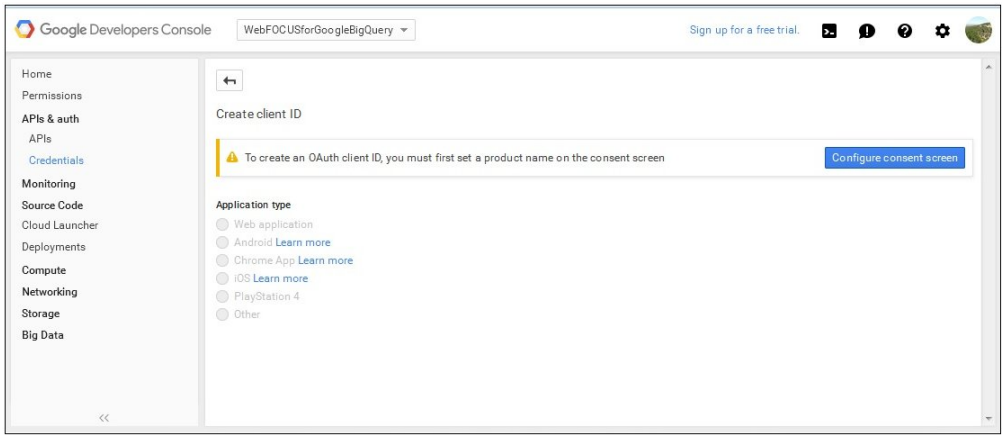
8. Click *Credentials* in the left pane.

   The APIs Credentials screen opens, as shown in the following image.



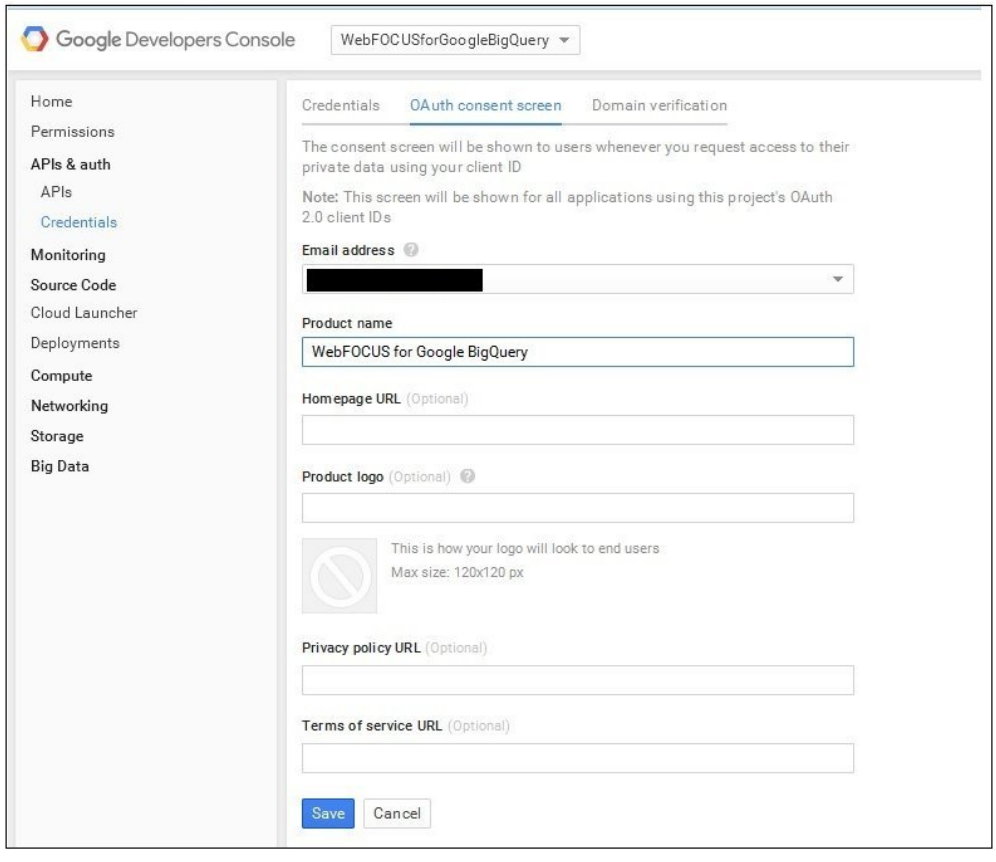
9. From the Add credentials drop-down list, click *OAuth 2.0 client ID*.

The Create client ID screen opens, as shown in the following image.



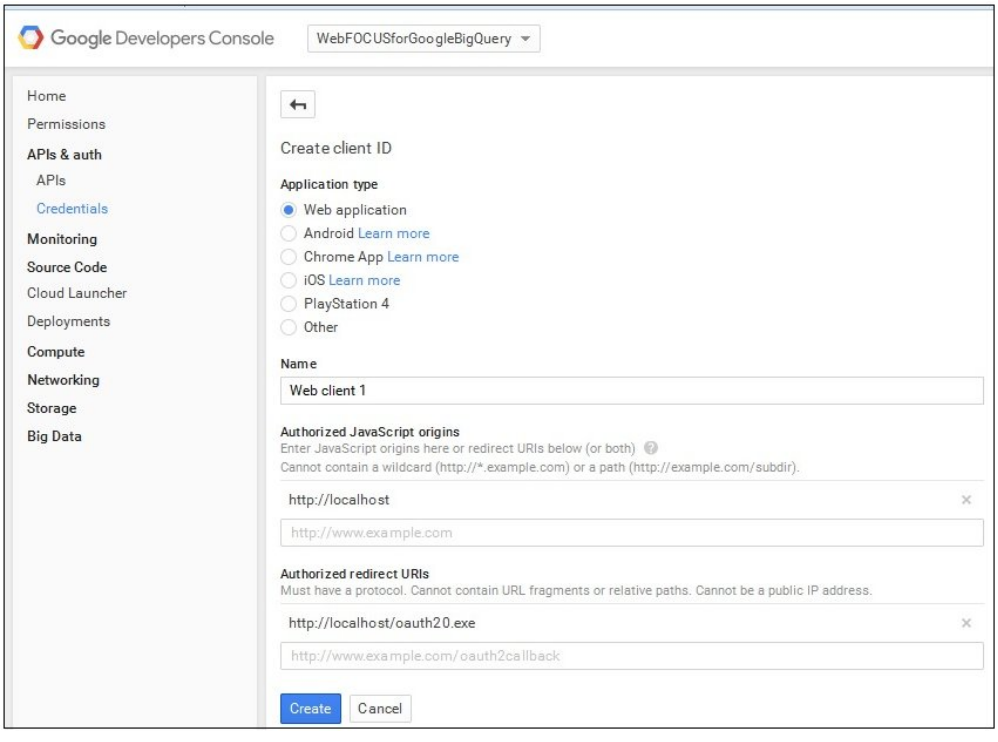
10. Click *Configure consent screen*.

The OAuth consent screen configuration opens, as shown in the following image.



11. Enter the Product Name that will appear on the Consent Screen, which will appear when you configure the Google BigQuery Adapter.
12. Click *Save*.

The Create Client ID page opens, as shown in the following image.



13. Perform the following steps:

    a. Select *Web application* from the list of application types.

    b. Enter the host name and port used to access the WebFOCUS Reporting Server Web Console in the AUTHORIZED JAVASCRIPT ORIGINS field.

       For example:

       ```
       http://host.ibi.com:8121
       ```

       If the WebFOCUS Reporting Server is installed as a standalone server, then *http://localhost* should be specified as the value in the AUTHORIZED JAVASCRIPT ORIGINS field.

    c. Enter the host name and port used to access the WebFOCUS Reporting Server Web Console with oauth20.exe in the AUTHORIZED REDIRECT URI field.

       For example:

       ```
       http://host.ibi.com:8121/oauth20.exe
       ```

If the WebFOCUS Reporting Server is installed as a standalone server, then *http://localhost/oauth20.exe* should be specified as the value in the AUTHORIZED REDIRECT URI field.

14. Click *Create*.

    The OAuth client screen containing the Client ID and Client Secret opens, as shown in the following image.

    Note: The *Client ID* and *Client secret* values are required to configure the Google BigQuery Adapter.

15. Click *OK*.

Configuring the Google BigQuery Adapter

This section describes how to configure the Google BigQuery Adapter.

Procedure: How to Configure the Google BigQuery Adapter

1. Clear the cookies from the web browser that will be used to start the WebFOCUS Reporting Server Web Console.
2. Access the WebFOCUS Reporting Server Web Console using the host name and port that you specified in the AUTHORIZED JAVASCRIPT ORIGINS field of the Google project.

   For example:

   ```
   http://host.ibi.com:8121
   ```

   For more information, see *How to Create a Google Project* on page 801.

3. From the Web Console Applications page, click *Get Data*.

   or

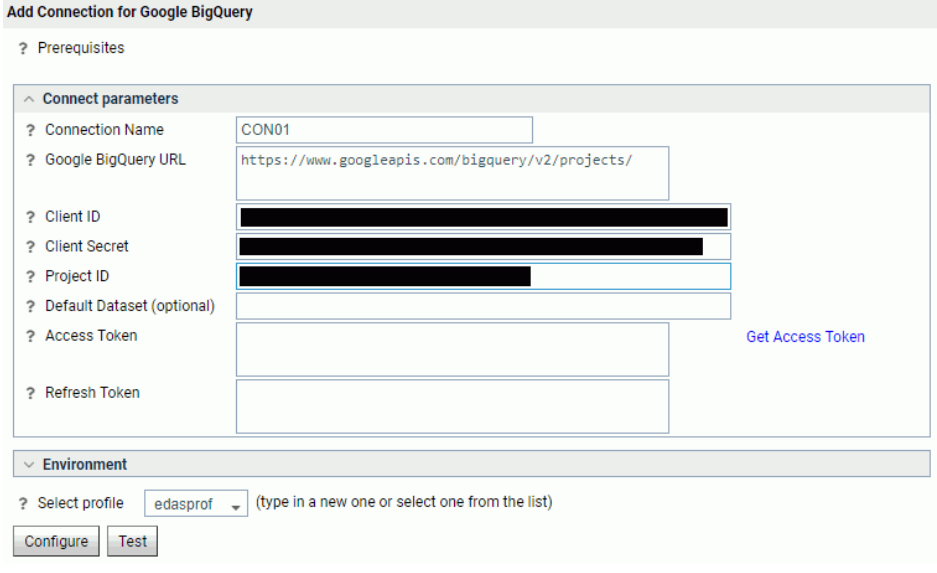
   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

4. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

5. Right-click the *Google BigQuery* node and select *Configure*

   The Add Connection for Google BigQuery pane opens, as shown in the following image.

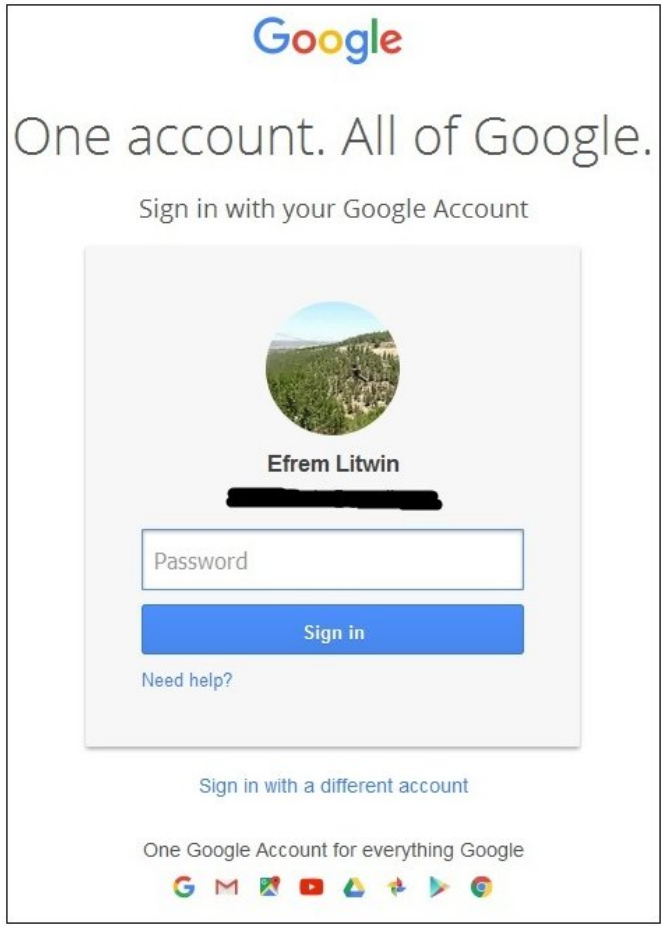


6. Enter the values for the Client ID, Client Secret, and Project ID as defined by the Client ID, Client secret, and Project ID respectively in the Google project.

   For more information, see *How to Create a Google Project* on page 801.

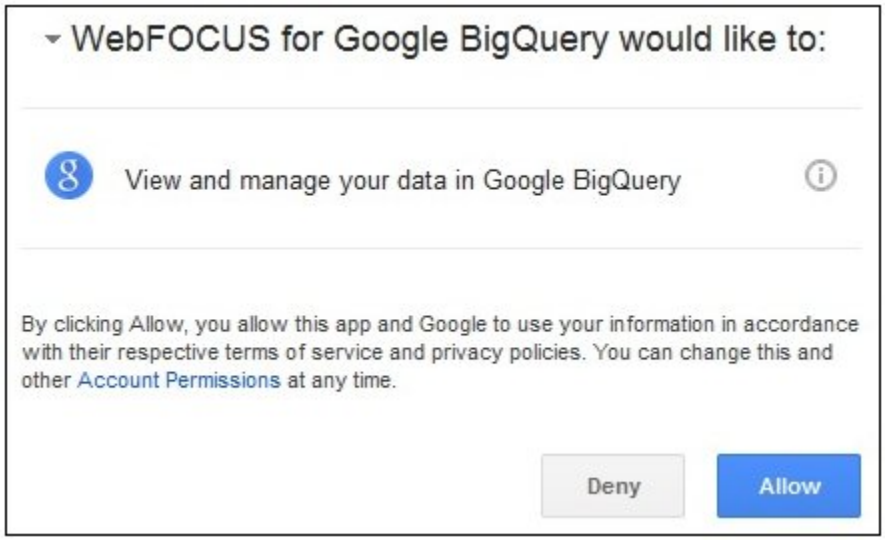
7. Click the *Get Access Token* link.

If you are not already signed into a Google account, a Google Sign In page opens, as shown in the following image.



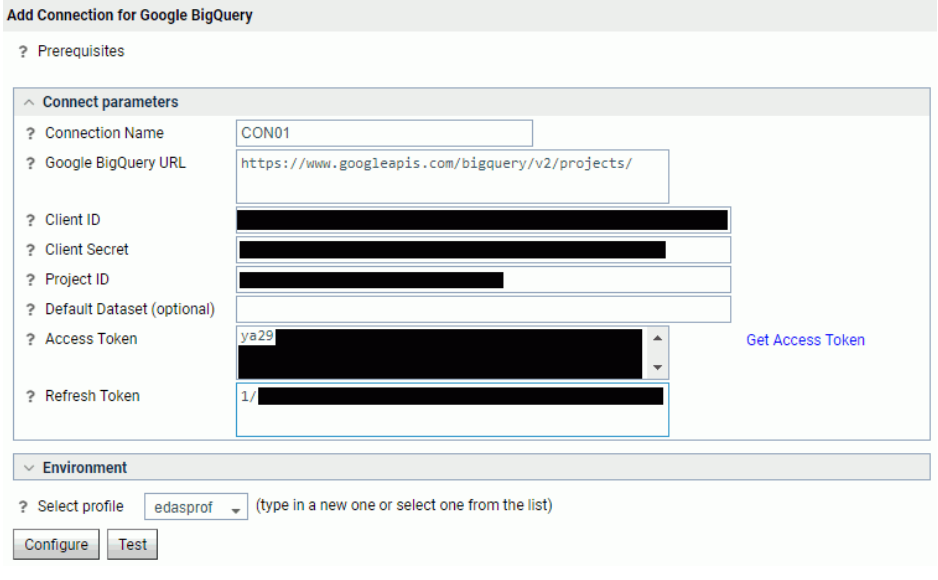
8. Enter the Google Sign In credentials and then click *Sign in*.

The Permissions Consent page opens, as shown in the following image.



9. Click *Allow*.

   You are returned to the Add Connection for Google BigQuery pane, where the Access Token field and Refresh Token field are now populated, as shown in the following image.



Note: If the Access and Refresh tokens are not populated, sign-off from your Google account and clear the browser cookies.

10. Click *Configure*.

    The Google BigQuery Adapter is added to the configured Adapters list in the navigation pane.

Reference: Connection Attributes for Google BigQuery

The following list describes the connection attributes for the Google BigQuery Adapter.

Connection Name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Google BigQuery URL

The URL of the Google BigQuery API request. The default value is:

```
https://www.googleapis.com/bigquery/v2/projects/
```

Client ID

The value that identifies your application to Google BigQuery.

Obtain this value using the following steps:

1. Go to:

   ```
   https://cloud.google.com/console/project
   ```

2. Click on the Project Name for the Google BigQuery Adapter application that was previously created.
3. Click *APIs & auth* in the left pane.
4. Click *Credentials* in the left pane.
5. Use Client ID in the Client ID for web application section.

Client Secret

The value which identifies your application to Google BigQuery. This value is used in conjunction with Client ID.

Obtain this value using the following steps:

1. Go to:

   ```
   https://cloud.google.com/console/project
   ```

2. Click on the Project Name for the Google BigQuery Adapter application that was previously created.
3. Click *APIs & auth* in the left pane.
4. Click *Credentials* in the left pane.
5. Click on the OAuth 2.0 client IDs Name eg. Web client 1.
6. Use Client Secret in the Client Secret for web application section.

Project ID

The ID that is associated with the Google application.

Obtain this value using the following steps:

1. Go to:

   `https://cloud.google.com/console/project`

2. Click on the Project Name for the Google BigQuery Adapter application that was previously created.
3. Click *Home* in the left pane.
4. Use ID for the selected application.

Default Dataset

Datasets allow you to organize and control access to your tables. Specify the default dataset you want to use for loading data into Google BigQuery.

Access Token

The value that identifies the user your application is acting on behalf. Click the *Get Access Token* link to obtain this token and the Refresh Token.

In order for the Get Access Token to complete successfully, the host name used to access the WebFOCUS Reporting Server Web Console must match the host name specified for the Redirect URI in the Google BigQuery application.

A Google sign-on screen opens if you are not already logged into a Google account.

A Consent screen opens. Click *Allow*.

If an issue arises when obtaining the Access and Refresh Tokens, clear your browser cache, including cookies.

Refresh Token

The Access Token has a very short lifespan. The Refresh Token is used to obtain a new Access Token during run time.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Creating Metadata for the Google BigQuery Adapter

Create Synonym for the Google BigQuery Adapter creates the metadata used for WebFOCUS reporting.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Google BigQuery

The following liast described the synonym creation parameters for which you can supply values.

Object Type

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

`Owner/Schema`
Select an owner/schema from the drop-down list, or click Search to search.

Project

Indicates the project associated with the Google BigQuery data.

Application

Select an application directory. The default value is baseapp.

`Customize data type mappings`
If checked, opens additional fields for decomposing date fields, adding geographic roles, and selecting the data type for numeric fields and for alphanumeric fields.

`Action`
Select *Create Base Synonyms*, *Create Cluster Synonym With BV*, or *Update Base Synonyms*.

Prefix

Assign a prefix to the synonym names.

Suffix

Assign a suffix to the synonym names.

Database

Select objects for which to create synonyms. If you selected *Create Cluster Synonym With BV* as the action, the list will have facts and dimensions. If you select a fact or dimension, you can right-click it to show or add related dimensions to the list of checked items for the cluster.

Click *Create Base Synonyms*, *Create Cluster Synonym With BV*, or *Update Base Synonyms* on the ribbon.

Chapter 31

Using the Adapter for Greenplum

The Adapter for Greenplum® provides greater flexibility for SQL optimization than generic JDBC.

In this chapter:

Configuring the Adapter for Greenplum

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a Greenplum data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one Greenplum data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

or

From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Greenplum

The Adapter for Greenplum is under the SQL group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the Greenplum data source. The basic syntax is:

```
jdbc:pivotal:greenplum://hostname:5432;DatabaseName=database
```

where:

hostname

Is the computer name or IP address on which the Greenplum database is located.

database

Is the name of the database.

Driver name

Name for the Greenplum driver: `com.pivotal.jdbc.GreenplumDriver`

See driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLGPDB SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

`SQLGPDB`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection name.

`URL`

Is the URL to the location of the Greenplum data source.

`userid`

Is the primary authorization ID by which you are known to the target database.

`password`

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the Greenplum Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or Data Management Console will encrypt the password before adding it to the server profile.

```
ENGINE SQLGPDB SET CONNECTION_ATTRIBUTES CON1
  'jdbc:xxxxxxx://hostname:port/datasource
```

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLGPDB SET DEFAULT_CONNECTION connection
```

where:

SQLGPDB

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLGPDB SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLGPDB SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

SQLGPDB

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Greenplum Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLGPDB to identify the Adapter for Greenplum.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLGPDB [,$]
```

where:

file

Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

`SQLGPDB`

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Greenplum

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Greenplum Data Type Support* on page 831.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Greenplum synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLGPDB ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Greenplum table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*

Keyword	Description
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. This attribute requires the columns that constitute the key to be described first in the Master File. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.

Keyword	Description
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Greenplum Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Data Type Mapping for A256V

The Adapter for Greenplum supports data type mapping using the following setting:

```
ENGINE SQLGPDB SET CONVERSION LONGCHAR ALPHA n
```

The setting affects the mapping of all native fields that have a data type of [VAR]CHAR(32767) or TEXT. The value of *n* ranges from 1 to 32767. The default value is 256. The TEXT data type (no *n* length) can be set instead of ALPHA when necessary.

Chapter 32

Using the Adapter for HP Vertica

The Adapter for HP Vertica allows applications to access specific HP Vertica data sources. The adapter converts application requests into HP Vertica calls and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the HP Vertica Environment

In order to use the Adapter for HP Vertica, you must install the HP Vertica driver for whichever data source you would like to access, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the HP Vertica Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some HP Vertica Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and checking that the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server EDAPRINT log. To resolve the problem, review the HP Vertica listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for HP Vertica

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a HP Vertica data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one HP Vertica data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for HP Vertica

The *HP Vertica* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the HP Vertica data source.

Driver name

Name for the HP Vertica driver:

```
com.vertica.jdbc.Driver
```

See driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLVRT SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

SQLVRT

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection name.

URL

Is the URL to the location of the HP Vertica data source.

userid

Is the primary authorization ID by which you are known to the target database.

password

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to data source using the HP Vertica Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

```
ENGINE SQLVRT SET CONNECTION_ATTRIBUTES CON1
  'jdbc:vertica://host:port'
```

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLVRT SET DEFAULT_CONNECTION connection
```

where:

SQLVRT

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLVRT SET DEFAULT_CONNECTION SAMPLE
```

Managing HP Vertica Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLVRT to identify the Adapter for HP Vertica.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLVRT [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLVRT

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for HP Vertica

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support Report* on page 845.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for HP Vertica synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLVRT ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,     DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the HP Vertica table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.

Keyword	Description
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support Report

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96

Customizing the HP Vertica Environment

The Adapter for HP Vertica provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to HP Vertica.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLVRT SET TIMEOUT {nn|0}
```

where:

`SQLVRT`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a timeout occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native HP Vertica driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLVRT SET PASSRECS {ON|OFF}
```

where:

`SQLVRT`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

HP Vertica Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 33

Using the Adapter for Hyperledger Fabric

The Adapter for Hyperledger Fabric allows you to seamlessly communicate with Hyperledger Fabric, which provides support for private permissioned blockchain applications. The adapter is designed for use with iWay Service Manager 8 (iSM 8), which enables users to integrate with a blockchain and utilize the intelligence of WebFOCUS, including the powerful BI and analytics platform, custom portals and dashboards, and trend analysis and reports.

Blockchain, or Distributed Ledger Technology (DLT), is a distributed record of transactions validated and stored at multiple peer locations in a network. The records form a consensus of replicated, shared, and synchronized information. The records stored in the blockchain are immutable, providing an extremely high level of security and integrity.

For more information, see the *iWay Service Manager and Blockchain Solutions Development Guide*.

In this chapter:

Preparing the Hyperledger Fabric Environment

The Adapter for Hyperledger Fabric requires the following to be configured.

- JDK 1.8 or above.
- The Hyperledger Fabric Java SDK. For information, see *Hyperledger Fabric Java SDK*. The SDK depends on a few third party libraries that must be included in your classpath. For information, see *Hyperledger Fabric Java SDK Documentation*.

Configuring the Adapter for Hyperledger Fabric

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for the Adapter for Hyperledger Fabric

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection Name
Is the logical name used to identify this set of connection attributes. The default is CON01.

PEERDEF
Is the endorser endpoint (the URL of the endorsing peer, in gRPC format).

The function of an endorsing peer is to endorse a transaction before it is committed for a particular chaincode. Every chaincode can specify an endorsement policy that may refer to a set of endorsing peers. The policy defines the necessary and sufficient conditions for a valid transaction endorsement. For example:

```
PeerAdmin@grpc://lnxx64hl2.ibi.com:7051
```

ORDERERDEF

Is the orderer endpoint (the URL of the ordering service node, in gRPC format).

The event hub is responsible for asynchronous processing of blockchain events. For example:

```
peer0@grpc://lnxx64hl2.ibi.com:7053
```

EVENTHUBDEF

Is the event hub peer endpoint (URL of peers that form the event hub, in gRPC format).

The orderers form the ordering service, a communication fabric that provides delivery guarantees. For example:

```
orderer@grpc://lnxx64hl2.ibi.com:7050
```

CHANNEL_ID

Is the channel name.

A channel is a private blockchain overlay that allows for data isolation and confidentiality. A channel-specific ledger is shared across the peers in the channel, and transacting parties must be properly authenticated to a channel in order to interact with it. For example:

```
mychannel
```

CHAINCODE_ID

Is the chaincode identifier.

A chaincode is software, running on a ledger, to encode assets and the transaction instructions (business logic) for modifying the assets. For example:

```
fabcar
```

PEER_ID

Is the member (user) name.

A member is a legally separate entity that owns a unique root certificate for the network. Network components such as peer nodes and application clients will be linked to a member. For example:

```
PeerAdmin
```

ORG_ID

Is the Membership Service Provider (MSP) Identifier.

The Membership Service Provider (MSP) refers to an abstract component of the system that provides credentials to clients and peers for them to participate in a Hyperledger Fabric network. Clients use these credentials to authenticate their transactions, and peers use these credentials to authenticate transaction processing results (endorsements). For example:

```
Org1MSP
```

CERT_LOC

Is the path to the enrollment certificate (ECert).

The ECert must have been signed by one of the Certificate Authorities (CAs) the blockchain network has been configured to trust. An enrolled user (having a signing key and ECert) can conduct chaincode instantiations, transactions, and queries with the channel. For example:

```
/qas/fabric_sdk100_sample/cert_car.pem
```

PKEY_LOC

Is the path to the private key.

```
/qas/fabric_sdk100_sample/key_car.pem
```

IBI_CLASSPATH

Are additional Java Class directories or full path names that will be available for Java Services. For example:

```
C:\directory\filename1.jar
C:\directory\filename2.jar
```

Managing Hyperledger Fabric Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Hyperledger Fabric data types.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Hyperledger Fabric

The following list describes the synonym creation parameters for which you can supply values. To create the synonym, click *Next*.

Application
Enter an application name in which to create the synonym, or click the ellipsis (...) to browse to an application folder.

Synonym Name
Enter a name for the synonym.

Function Name

Is the name of a chaincode function. For example:

```
TradingNetwork
```

Function Arguments

Are the function arguments. If there are multiple arguments, separate them with vertical bar characters (|). For example:

```
FromParty|ToParty|Amount|MessageReference
```

Chapter 34

Using the Adapter for Hyperstage

The Adapter for Hyperstage allows applications to access Hyperstage data sources. The adapter converts application requests into native Hyperstage statements and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the Hyperstage Environment

The Adapter for Hyperstage requires the MySQL Connector/J JDBC driver. The Adapter for Hyperstage PG uses the Postgres Connector/J JDBC driver. Where required to differentiate between settings for each version, the Posgres version is referred to as the Adapter for Hyperstage PG.

Procedure: How to Prepare the Hyperstage Environment on Windows

1. Specify the location of the Postgres or MySQL Connector/J JDBC driver file in the CLASSPATH environment variable. You must specify the full location and name of the jar file.

   For example, for the mySQL version, if the jar file is located in C:\Program Files \Hyperstage\JDBC Driver, then specify:

   ```
   CLASSPATH= C:\Program Files\Hyperstage\JDBC Driver\mysql-connector-
   java-5.1.18-bin.jar
   ```

   For example, for the Hyperstage PG version, if the jar file is located in C:\ibi \srv99\homeHyperstage\hs\java, then specify:

   ```
   CLASSPATH= C:\ibi\srv99\homeHyperstage\hs\java
   \postgresql-9.2-1003.jdbc3.jar
   ```

or

```
CLASSPATH= C:\ibi\srv99\homeHyperstage\hs\java
\postgresql-9.2-1003.jdbc4.jar
```

2. Specify the location of the Java run time environment or development kit in the JAVA_HOME or JDK_HOME environment variable. Either is acceptable.

   You must specify the location where the run time environment is installed. You should see a sub-directory bin in that directory. For example, if you have the run time environment in C:\Program Files\java\jre6 then specify:

   ```
   JAVA_HOME=C:\Program Files\java\jre6
   ```

   Alternately, if you have the full development kit installed in C:\Program Files\java \jdk1.6.0_17, then specify:

   ```
   JDK_HOME= C:\Program Files\java\jdk1.6.0_17
   ```

3. Start (or restart) the server.

Note: You also need to restart the server if the driver has changed.

Procedure: How to Prepare the Hyperstage Environment on UNIX

Specify the location of several files:

1. Specify the location of the MySQL Connector/J JDBC driver files in the $CLASSPATH environment variable.

   For example, if the file is located in /usr/driver_files, you would issue the following statements for the mySQL version:

   ```
   CLASSPATH=/usr/driver_files/mysql-connector-java-5.1.18-bin.jar;
   $CLASSPATH
   export CLASSPATH
   ```

   For example, if the file is located in /usr/driver_files, you would issue the following statements for the Hyperstage PG version:

   ```
   CLASSPATH=/usr/driver_files/postgresql-9.2-1003.jdbc4.jar;$CLASSPATH
   export CLASSPATH
   ```

   To ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

   Alternatively, you could use the Web Console to specify the location:

   a. Select the *Workspace* menu option.

   b. Expand the *Java Services* folder, right-click *DEFAULT*, and select *Properties*.

The Java Services Configuration pane opens.

c. Select the *Class path* section.

d. Specify the full path to the MySQL Connector/J jar file in the IBI_CLASSPATH field.

e. Click *Save and Restart Java Services*.

2. Specify the location of the Java Development Kit's installation directory in the $JDK_HOME environment variable.

   For example, if you want to set the location of the Java Development Kit to /usr/java, you would issue the following statements:

   ```
   JDK_HOME=/usr/java
   export JDK_HOME
   ```

3. Specify the location of the Java Virtual Machine's installation directory in the $LD_LIBRARY_PATH environment variable.

   For example, if you want to set the location of the JVM to /usr/j2sdk1.4.2_01/jre/lib/i386/server, you would issue the following statements:

   ```
   LD_LIBRARY_PATH=/usr/j2sdk1.4.2_01/jre/lib/i386/server
   export LD_LIBRARY_PATH
   ```

   Note that if the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.

4. Start (or restart) the server.

Note: You also need to restart the server if the driver has changed.

Hyperstage and Unicode

The Adapter for Hyperstage is implemented using JDBC. This implementation supports Unicode data stored in character fields with the CHARACTER SET set to UTF-8.

You must set the LANG environment variable in the edastart file or in a separate shell file before you start the server. For example, for American English you would export the following variable:

```
export LANG=EN_US.UTF-8
```

For details, see *Unicode Support* in the *Server Administration* manual.

Configuring the Adapter for Hyperstage

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

The SET CONNECTION_ATTRIBUTES command allows you to declare a connection to one Hyperstage database server and to supply authentication attributes necessary to connect to the server.

You can declare connections to more than one Hyperstage database server by issuing multiple SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query referencing that connection is issued (see *Overriding the Default Connection* on page 864). You can include SET CONNECTION_ATTRIBUTES commands in an RPC or a server profile. The profile can be encrypted.

If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The *first* SET CONNECTION_ATTRIBUTES command sets the default Hyperstage database server to be used.
- If more than one SET CONNECTION_ATTRIBUTES command declares the same Hyperstage database server, the authentication information is taken from the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Hyperstage PG

The Hyperstage PG adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Enter the location URL for the Hyperstage data source. The basic syntax is

```
jdbc:postgresql://host:port/database
```

where:

host

Is the computer name or IP address on which the Hyperstage database is located.

port

Is the port number used to access the Hyperstage database

database

Is the name of the database.

These are two examples:

```
jdbc:postgresql://localhost:8101/qatst
```

```
jdbc:postgresql://edaaix52:8101/qatst
```

Driver name

Name of the JDBC driver: `org.postgresql.Driver`

Home Directory

The full path name to the Hyperstage installation directory. For example, C:\ibi\srv77\home\hs.

Tools Directory

The full path name to the Hyperstage Tools directory. For example, C:\ibi\srv77\home\hs\bin.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Reference: Connection Attributes for Hyperstage

The Hyperstage adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Enter the location URL for the Hyperstage data source. The basic syntax is

```
jdbc:mysql://host:port/database
```

where:

host

Is the computer name or IP address on which the Hyperstage database is located.

port

Is the port number used to access the Hyperstage database

database

Is the name of the database.

These are two examples:

```
jdbc:mysql://localhost:8101/qatst
```

```
jdbc:mysql://edaaix52:8101/qatst
```

You can reference additional Hyperstage connection properties in the URL. If you wish to do so, follow these guidelines: in the URL the first property must be preceded by the ? character, and the second and subsequent properties referenced in the URL must be preceded by the & character followed immediately by an | character, as illustrated in the following example.

Suppose that you wish to add the following connection properties:

```
sessionVariables=sql_mode=PIPES_AS_CONCAT
 zeroDateTimeBehavior=convertToNull
```

Enter the URL as follows:

```
jdbc:mysql://host/database?sessionVariables=sql_mode=P
IPES_AS_CONCAT&|
 zeroDateTimeBehavior=convertToNull
```

Note: The URL must be entered as a single line, without a space after the | character.

Driver name

Name of the JDBC driver: `com.mysql.jdbc.Driver`

Home Directory

The full path name to the Hyperstage installation directory. For example, C\ibi\Hyperstage.

Tools Directory

Hyperstage Tools directory.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

For explicit authentication:

```
ENGINE SQLHYP SET CONNECTION_ATTRIBUTES [connection]/userid,password
```

For password passthru authentication:

```
ENGINE SQLHYP SET CONNECTION_ATTRIBUTES connection/
```

where:

SQLHYP

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

For the Postgres version of the adapter, use SQLHYPG.

connection

The name of the connection. You can give any name to the connection that you want.

userid

Is the primary authorization ID by which you are known to Hyperstage.

password

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to the Hyperstage database server named TEST with an explicit user ID and password:

```
ENGINE SQLHYP SET CONNECTION_ATTRIBUTES TEST/USERA,PWDA
```

The following SET CONNECTION_ATTRIBUTES command connects to the Hyperstage database server named TEST using password passthru authentication:

```
ENGINE SQLHYP SET CONNECTION_ATTRIBUTES TEST/
```

Authenticating a User

There are two methods by which a user can be authenticated when connecting to a Hyperstage database server:

- **Explicit.** User IDs and passwords are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users.
- **Database or Password Passthru.** User ID and password received from the client application are passed to the Hyperstage database server for authentication.

When a client connects to the server, the user ID and password are passed to Hyperstage for authentication and are not authenticated by the server. To implement this type of authentication, start the server with security turned off. The server allows the client connection, and then stores an encrypted form of the client connection message to be used for connection to a Hyperstage database server at anytime during the lifetime of the server agent.

Overriding the Default Connection

Once all Hyperstage connections to be accessed have been declared using the SET CONNECTION_ATTRIBUTES command, there are two ways to select a specific Hyperstage connection from the list of declared connections:

- You can select a default connection using the SET DEFAULT_CONNECTION command. If you do not issue this command, the connection name value specified in the *first* SET CONNECTION_ATTRIBUTES command is used.
- You can include the CONNECTION= attribute in the Access File of the table specified in the current SQL query. When you include a connection name in the CREATE SYNONYM command from the Web Console, the CONNECTION= attribute is automatically included in the Access File. This attribute supersedes the default connection.

Syntax: How to Select a Connection to Access

```
ENGINE SQLHYP SET DEFAULT_CONNECTION [connection]
```

where:

`SQLHYP`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

For the Postgres version of the adapter, use SQLHYPG.

`connection`

Is the connection name specified in a previously issued SET CONNECTION_ATTRIBUTES command. If omitted, then the local database server will be set as the default. If this connection name has not been previously declared, a FOC1671 message is issued.

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command will be the active connection name.

- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, a FOC1671 message is issued.

Example: Selecting a Connection to Access

The following SET DEFAULT_CONNECTION command selects the Hyperstage database server named SAMPLESERVER as the default Hyperstage database server:

```
ENGINE SQLHYP SET DEFAULT_CONNECTION SAMPLESERVER
```

Note: You must have previously issued a SET CONNECTION_ATTRIBUTES command for the datasource_name.

Controlling Connection Scope

This topic explains how to set the scope of logical units of work using adapters. This is accomplished by the SET AUTODISCONNECT command.

A connection occurs at the first interaction with the declared database server.

Syntax: How to Control the Connection Scope

```
ENGINE SQLHYP SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

SQLHYP

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN

Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Hyperstage Metadata

This topic describes how to use CREATE SYNONYM for Hyperstage data sources. It also describes Hyperstage data type support.

Creating Synonyms

Synonyms define unique names (or aliases) for each Hyperstage table or view that is accessible from the server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Hyperstage

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Object name

Selecting this option adds the Object Name parameters to the screen.

Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Hyperstage Data Type Support* on page 872.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Type

The object type (Table, View, and so on).

Table name

Is the name of the underlying object.

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Hyperstage synonym comprises a Master File and an Access File. This is a synonym, using the mySQL version of the adapter for the table nf29004.

Generated Master File nf29004.mas

```
FILENAME=NF29004, SUFFIX=SQLHYP  , $
SEGMENT=NF29004, SEGTYPE=S0, $
FIELDNAME=DIVISION4, ALIAS=DIVISION4, USAGE=I11, ACTUAL=I4, $
FIELDNAME=DIVISION_NA4, ALIAS=DIVISION_NA4, USAGE=A25, ACTUAL=A25,
MISSING=ON, $
FIELDNAME=DIVISION_HE4, ALIAS=DIVISION_HE4, USAGE=I11, ACTUAL=I4,
MISSING=ON, $
```

Note: For the Postgres version of the adapter, the SUFFIX value would be SQLHYPG.

Generated Access File nf29004.acx

```
SEGNAME=NF29004, TABLENAME=NF29004, CONNECTION=CON1, KEYS=0, $
```

Reference: Access File Keywords

This chart describes keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Hyperstage tablename. The tablename may include owner (schema) name. For example, TABLENAME=[*owner.*]*tablename*

Keyword	Description
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local database server. Absence of the CONNECTION attribute indicates access to the default database server.
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. Since Hyperstage does not support indexes, the default value is 0. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❏ KEYFLD is the FIELDNAME of the common column from the parent table. ❏ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Keyword	Description
AUTO INCREMENT	Not applicable for Hyperstage.
START	Not applicable for Hyperstage.
INCREMENT	Not applicable for Hyperstage.
INDEX_NAME INDEX_UNIQUE INDEX_COLUMNS INDEX_ORDER	Not applicable for Hyperstage.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Hyperstage Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96

Customizing the Adapter for the Hyperstage Environment

This topic describes how to set the adapter for the Hyperstage environment.

PASSRECS

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Set PASSRECS

```
ENGINE SQLHYP SET PASSRECS {ON|OFF}
```

where:

`SQLHYP`

Indicates adapter. You can omit this value if you previously issued the SET SQLENGINE command.

For the Postgres version of the adapter, use SQLHYPG.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Specifying the Transaction Isolation Level

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

Syntax: How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

```
ENGINE SQLHYP SET ISOLATION {RU|RC|RR|SE}
```

where:

SQLHYP

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

For the Postgres version of the adapter, use SQLHYPG.

RU

Sets the transaction isolation level to Read Uncommitted.

RC

Sets the transaction isolation level to Read Committed.

RR

Sets the transaction isolation level to Repeatable Read.

SE

Sets the transaction isolation level to Serializable Read.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Hyperstage Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109 and *Optimizing Requests to Pass Virtual Fields Defined as Constants* on page 112.

Chapter 35

Using the Adapter for i Access

The Adapter for i Access allows applications to access system i data sources using odbc and jdbc from windows and unix environments. The adapter converts application requests into native ODBC/JDBC calls and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the i Access Environment (ODBC)

In order to use the Adapter for i Access, you must install the IBM i Access for Windows client on the box where the server will be running.

Preparing the i Access Environment (JDBC)

In order to use the Adapter for JDBC, you must install the JDBC driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the JDBC Environment on Windows and UNIX

1. Identify the location of the JDBC Driver files by adding them to the environment variable *CLASSPATH* before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   On UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

Similarly, on Windows, you would issue the command:

```
set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
```

Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

2. Start, or restart. the server.

   Note that you also need to restart the server if the driver has changed.

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace and checking that the special services section displays *JSCOM3 active*.

   ```
   edastart -show
   ```

   If the JSCOM3 service is not active, a *fail to start* message will typically also be inserted in the server EDAPRINT log. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for i Access

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to the i database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one i Access database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the i Access Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for i Access (ODBC)

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

SYSTEM

Name of the machine where the IBM i system is running.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.
- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Default Library (optional)

Specifies the IBM i libraries to add to the server job library list. The library list is used for resolving unqualified stored procedure calls and finding libraries in catalog API calls.

Additional connection string keywords (optional)

Refer to IBM i access documentation for all available connection string keywords used to change the behavior of the ODBC connection.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually (ODBC)

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to i Access, at connection time, for authentication.

For User/System DSN:

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES connection DSN_SAMPLE/
userid,password
```

Password passthru authentication. The user ID and password are explicitly specified for each connection and passed to IBM i, at connection time, for authentication.

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES connection DSN_SAMPLE/
```

Trusted authentication. The adapter connects to IBM i as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES connection DSN_SAMPLE/,
```

Example: Declaring Connection Attributes (ODBC)

For User/System DSN:

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the i Access DSN server named SAMPLE with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify OS4V71P1 connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES CON1 SAMPLE/MYUSER,PASS
```

Reference: Connection Attributes for i Access (JDBC)

The IBM i Access adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the JDBC data source.

Driver name

Name for the JDBC driver.

For information, see the driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. This value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Syntax: How to Declare Connection Attributes Manually (JDBC)

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES connection 'url'/userid,password
```

where:

`SQLIIA`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection name.

`url`

Is the URL to the location of the JDBC data source.

userid

Is the primary authorization ID by which you are known to the target database.

password

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes (JDBC)

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the JDBC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

```
ENGINE SQLIIA  SET CONNECTION_ATTRIBUTES CON1
'jdbc:xxxxxxx://hostname:port/datasource'/MYUSER,PASS
```

Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console Migrate option migrates your server settings to the newer release. To access this option, select *Workspace*, then *Configuration/Monitor* from the menu bar. Right-click *Migrate* from the *Server* folder in the navigation pane, and select *Configure*. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the *Migrate* button. This is the recommended approach.

If you choose *not* to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=*value*.

  For example, suppose that prior 7.6.1 the connection was defined as:

  ```
  ENGINE SQLIIA SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
  ```

When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

```
CONNECTION=DSN_A
```

If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

```
ENGINE SQLIIA SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLIIA SET DEFAULT_CONNECTION connection
```

where:

`SQLIIA`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: **Selecting the Default Connection**

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLIIA SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: **How to Control the Connection Scope**

```
ENGINE SQLIIA SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

`SQLIIA`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMAND`

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing i Access Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLIIA to identify the Adapter for i Access.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLIIA [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLIIA

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.

- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for i Access

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *i Access Data Type Support* on page 891.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for i Access synonym comprises a Master File and an Access File. This is a synonym for the table TYEAR.

Master File

```
FILENAME=TYEAR, SUFFIX=SQLIIA  , $
  SEGMENT=TYEAR, SEGTYPE=S0, $
    FIELDNAME=MONTH, ALIAS=MONTH, USAGE=A6V, ACTUAL=A6V, $
    FIELDNAME=YEAR, ALIAS=YEAR, USAGE=A6V, ACTUAL=A6V,
      MISSING=ON, $
    FIELDNAME=QUARTER, ALIAS=QUARTER, USAGE=A6V, ACTUAL=A6V,
      MISSING=ON, $
    FIELDNAME=MONTH_CAPTION, ALIAS=MONTH_CAPTION, USAGE=A6V, ACTUAL=A6V,
      MISSING=ON, $
```

Access File

```
SEGNAME=TYEAR,
   TABLENAME=DB999.TYEAR,
   CONNECTION=CON01,
   KEY=MONTH, $
  INDEX_NAME=TYEARIX,
      INDEX_UNIQUE=Y,
      INDEX_COLUMN=MONTH,
      INDEX_ORDER=ASC, $
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the table name. For IBM i, the synatx is: TABLENAME=[*library*.]*tablename*

Keyword	Description
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection*
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.
INDEX_NAME INDEX_UNIQUE INDEX_COLUMNS INDEX_ORDER	Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

i Access Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the i Access Environment

The Adapter for i Access provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to IBM i.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLIIA SET TIMEOUT {nn|0}
```

where:

`SQLIIA`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

0

Represents an infinite period to wait for a response.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLIIA SET PASSRECS {ON|OFF}
```

where:

SQLIIA

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Specifying the Transaction Isolation Level

You can specify the transaction isolation level from the Web Console or using the SET ISOLATION command.

Syntax: How to Specify Transaction Isolation Level From a SET Command

You can specify transaction isolation level by issuing the following command

```
ENGINE SQLIIA SET ISOLATION {RU|RC|RR|SE}
```

where:

RU

Sets the transaction isolation level to Read Uncommitted.

RC

Sets the transaction isolation level to Read Committed.

RR

Sets the transaction isolation level to Repeatable Read.

SE

Sets the transaction isolation level to Serializable Read.

i Access Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 36

Using the Adapter for CA-IDMS/DB

The Adapter for CA-IDMS/DB for z/OS allows applications to access IDMS/DB data sources. The adapter converts application requests into native IDMS/DB statements and returns optimized answer sets to the requesting application.

Note: In the remainder of this topic, the following terms all refer to the Adapter for CA-IDMS/DB:

- CA-IDMS/DB
- IDMS/DB
- Adapter for IDMS/DB

In this chapter:

Preparing the IDMS/DB Environment

Prior to configuring the Adapter for IDMS/DB using the Web Console, it is necessary to edit the ISTART JCL that is used to initiate the server.

Procedure: How to Edit the ISTART JCL

1. Allocate the IDMS.LOADLIB and IDMS.DBA.LOADLIB libraries to the server STEPLIB DDNAME allocation.
2. Allocate DDNAME SYSCTL to the IDMS.SYSCTL data set.
3. Allocate DDNAME SYSIDMS to the IDMS.SYSIDMS data set.

Configuring the Adapter for IDMS/DB

You can configure the Adapter for IDMS/DB from the Web Console or the Data Management Console.

The integrity of the IDMS/DB data source is not jeopardized because the adapter provides read-only access. Access to the data source is restricted by the security package in use on the z/OS system (such as RACF) and by the CA-IDMS/DB security features.

Both CA-IDMS/DB and the server provide security mechanisms to ensure that users have access to only those objects for which they have authorization.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

IDMS/DB Overview and Mapping Considerations

CA-IDMS/DB databases, both network and LRF-based, correspond to hierarchical and relational data sources. The concepts discussed in this section affect the way IDMS/DB files are described to the server.

Mapping Concepts

IDMS/DB is a network database management system that is accessed by a subschema (the equivalent in the server is a Master File). IDMS/DB provides two methods of retrieving records within a subschema from an application program:

- Network access (DML)
- LRF-based access (LRF)

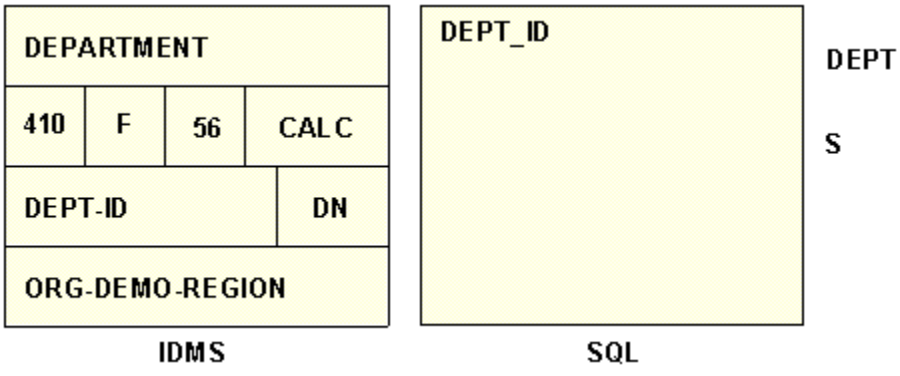
Data Management Language (DML) access is the traditional method of IDMS/DB database navigation. It is the network navigation facility. Each physical record is retrieved separately. An application program enters the IDMS/DB database at a particular IDMS/DB record type (the equivalent in the server is a segment) and searches the set connections to retrieve the required data. For mapping concepts that apply to network record types, see *Summary of Network Relationships* on page 909.

Logical Record Facility (LRF) access, available as of IDMS/DB Release 5.7, is the relational-like method of access. LRF provides software to dynamically create flat records from one or more network record types at run time. For mapping concepts that apply to LRF-based records, see *Logical Record Facility Concepts* on page 907.

Network Concepts

An IDMS/DB record type is described to the server as a segment. Since DML retrieval is record-oriented rather than field-oriented, the Master File must list the fields in the same order as they appear on the IDMS/DB record type. However, a Master File does not have to list every field of a particular record type; you may omit fields after a given field. For example, your description may list the first four fields of a 10-field IDMS/DB record type. You can use IDMS/DB field names in your Master File up to a maximum of 48 characters.

The following diagram illustrates how a record type is described as a segment. The record type DEPARTMENT contains the field-type DEPT-ID. Its corresponding server segment DEPT contains a field named DEPT_ID.



Repeating fields on an IDMS/DB record type are defined as OCCURS segments.

Network record types may be related to each other. These relationships may be physical (using set connections) or logical (achieved through an index or CALC field). The Adapter for IDMS/DB supports both physical and logical relationships.

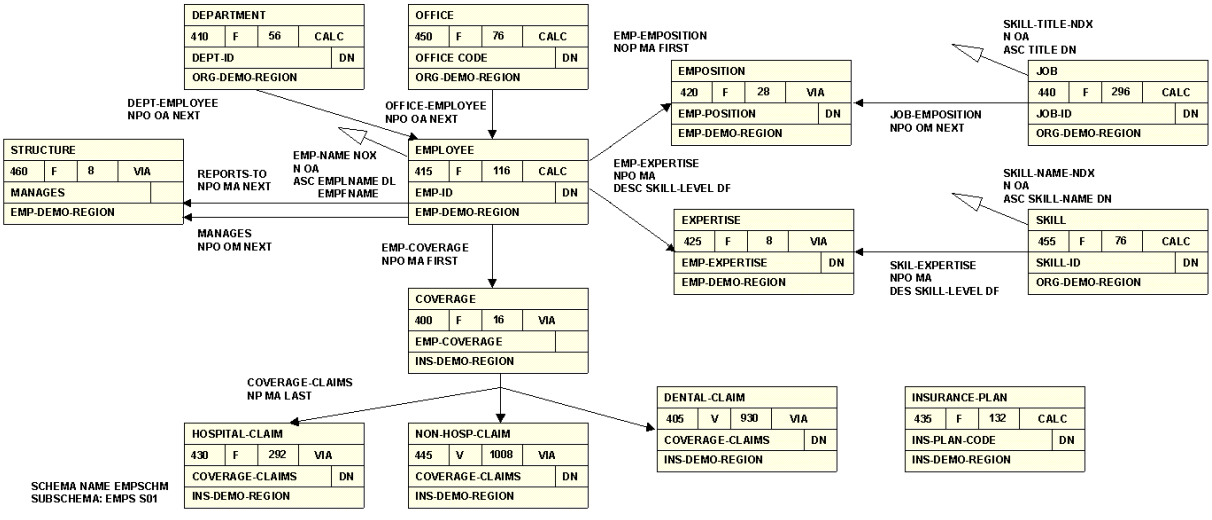
Set-Based Relationships

In an IDMS/DB database, physical relationships between record types are achieved with pointers that correspond to IDMS/DB sets. A set implements a one-to-many relationship between record types. The server equivalent of a set is the parent/descendant relationship between segments. In an IDMS/DB set, one record type acts as the owner (the one side of the relationship) and one or more record types act as the members (the many side of the relationship). A single IDMS/DB record type can participate in several set relationships as either the owner or the member.

The IDMS/DB representation of record types and set relationships within a database is called a Bachman diagram, also known as a data structure diagram. In a Bachman diagram, a record type is depicted as a box; a set, as a line with an arrow. Set names appear as labels beside the arrows. The box that the arrow points to is the member record type. Triangles indicate indexes. The next diagram is the Bachman diagram for the IDMS/DB network subschema EMPSS01. Sections of this diagram are referenced throughout these sections.

The following kinds of set-based relationships are depicted: simple set, common owner, common member, multi-member, bill-of-materials (simple and multi-tiered), and loop structures.

All relationships correspond to server structures and are explained following the diagram:



Simple Set

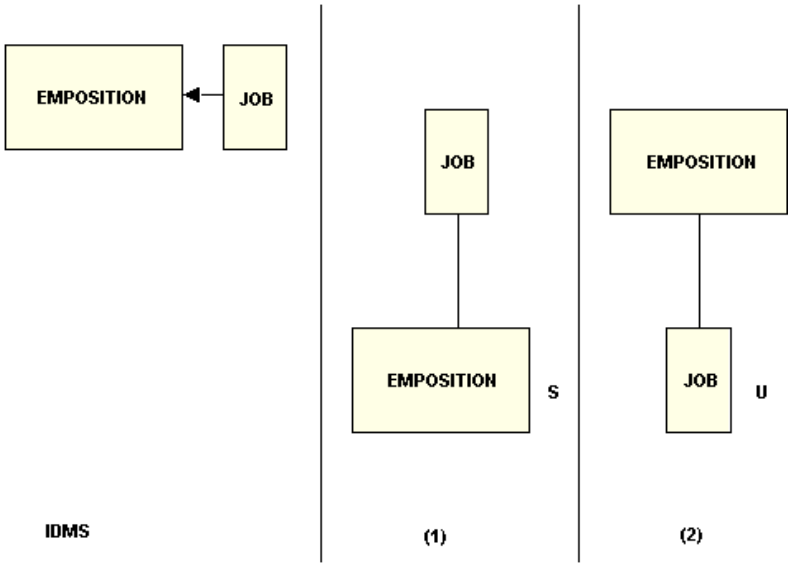
The following diagram illustrates the basic mapping principle of a simple set: an IDMS/DB record type corresponds to a segment; a set relationship corresponds to a parent/descendant relationship.

This figure also illustrates a second principle: an IDMS/DB structure can have more than one representation as a hierarchy. The type of parent/descendant relationship required in the Master File depends on whether the owner or the member record type is designated as the parent segment.

The JOB-EMPOSITION set has two possible representations:

1. It shows the JOB record type, the owner in the set, mapped to the server as the root segment. Since a member record type is multiply-occurring (for example, several instances of EMPOSITION records per JOB instance, indicating that many positions share one job title and description), the EMPOSITION record type is displayed as a non-unique descendant.

2. It depicts the reverse. The EMPOSITION record type is the root segment and JOB is the unique descendant, since an EMPOSITION instance can have only one owner (only one job title and description per position).



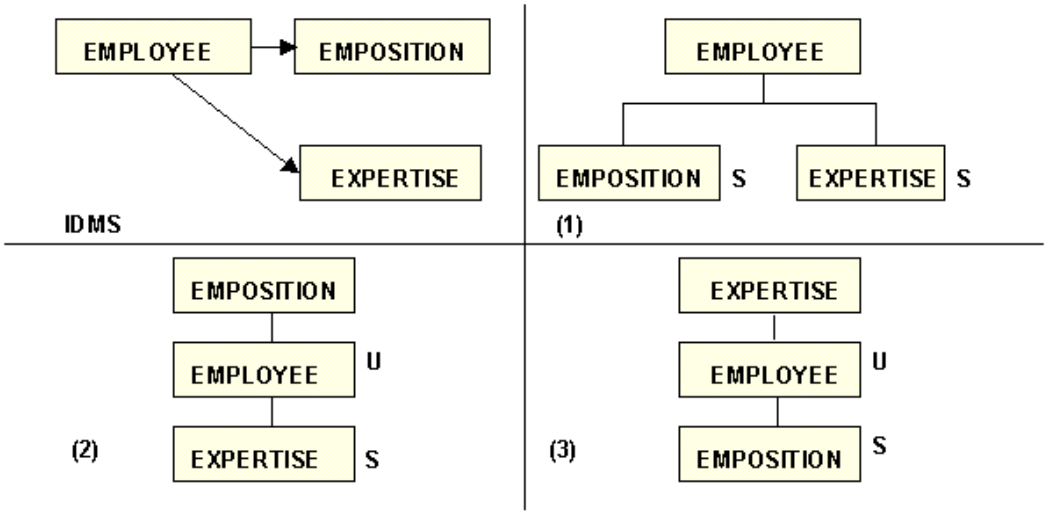
Common Owner

Given the rules in the previous example, consider a more complex scenario called a common owner. A common owner structure contains a record type that is the owner of two or more record types. Several representations are possible.

For example, the diagram below depicts three ways to describe the EMPLOYEE, EXPERTISE, and EMPOSITION structure in one Master File:

1. It shows the EMPLOYEE record type, the owner in both sets, mapped to the server as the root segment of EMPOSITION and EXPERTISE. Since an EMPLOYEE record can have many EMPOSITION and EXPERTISE records, both descendant records are non-unique.
2. It depicts the EMPOSITION record type as the root segment of EMPLOYEE, which acts as the parent of EXPERTISE. Since an EMPOSITION record can have only one owner, EMPLOYEE is a unique descendant; EXPERTISE is a non-unique descendant of EMPLOYEE.

3. It depicts the EXPERTISE record type as the parent of EMPLOYEE, which acts as the parent of EMPOSITION. EMPLOYEE is a unique descendant and EMPOSITION is a non-unique descendant of EMPLOYEE.



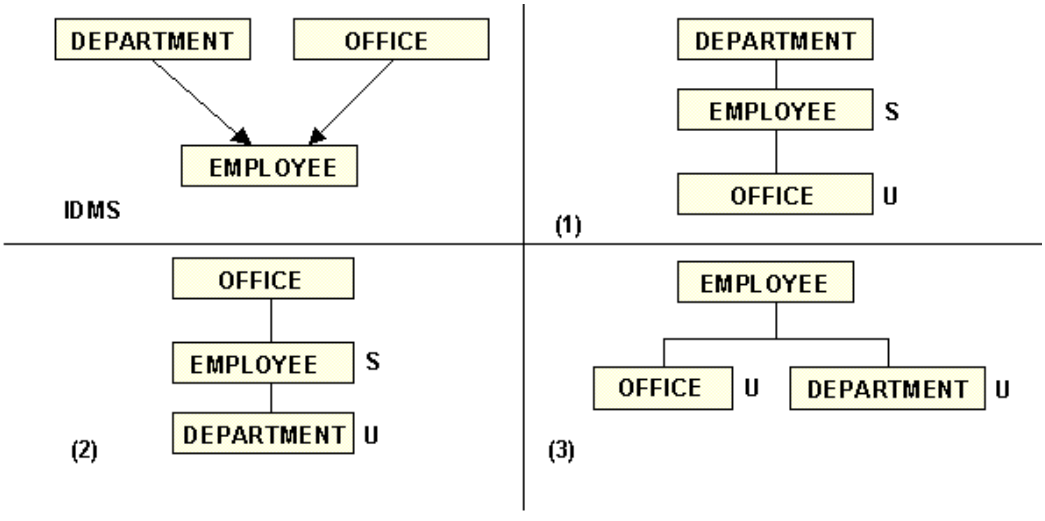
Common Member

When an IDMS/DB record type is a member of two or more sets, the association of the owner record type as the parent segment must be abandoned for one or more sets, because a segment can have only one parent. The diagram below displays the possible interpretations for this IDMS/DB configuration.

In the diagram, the EMPLOYEE record type is a common member in the DEPT-EMPLOYEE and the OFFICE-EMPLOYEE sets. This structure can be described to the server in three ways:

1. It shows DEPARTMENT as the root segment with EMPLOYEE as its non-unique descendant. OFFICE is the unique descendant of EMPLOYEE.
2. It depicts the reverse: OFFICE is the root segment; EMPLOYEE is its non-unique descendant; and DEPARTMENT is the unique descendant of EMPLOYEE.

3. It shows the only other alternative: EMPLOYEE is the parent of OFFICE and DEPARTMENT. Both are unique, since an EMPLOYEE can belong to only one OFFICE and DEPARTMENT.



Notice that the rules for simple sets are still valid:

- If the owner record type is the parent segment, the member record type as a descendant segment is non-unique.
- If the member record type is the parent segment, the owner record type as a descendant segment is unique.
- A member or an owner record type may act as a root segment (the server ignores whether the root segment is unique or non-unique).

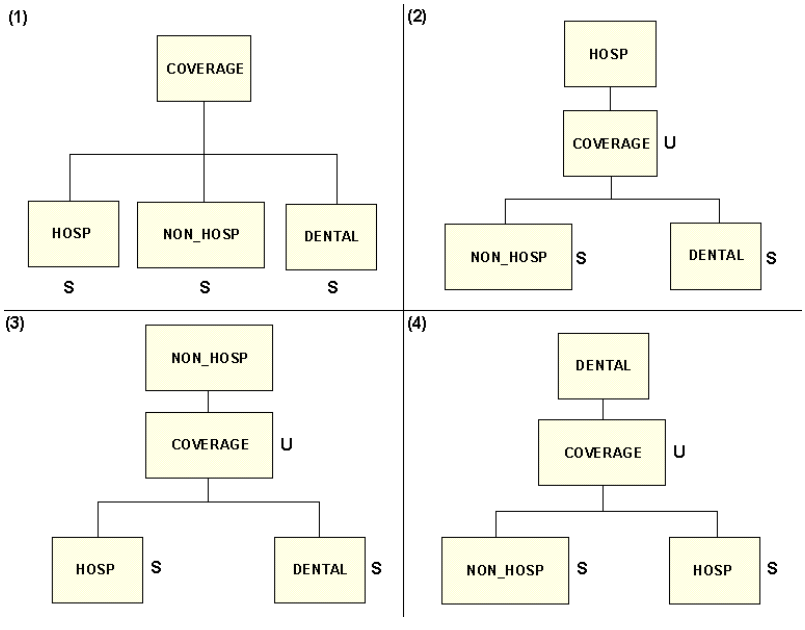
It may be helpful to think of the hierarchical depiction of a network structure as its navigational path. From an IDMS/DB standpoint, panel 1 of the previous diagram shows that the IDMS/DB database can be entered at the DEPARTMENT record type. The corresponding EMPLOYEE record occurrences for a DEPARTMENT record occurrence can be obtained by searching the DEPT-EMPLOYEE set. For each EMPLOYEE record occurrence, obtaining the owner in the OFFICE-EMPLOYEE set retrieves the corresponding OFFICE record occurrence. This is a three-segment retrieval hierarchy that maps to server descriptions.

Multi-Member

When there is more than one member record type, the set is called a multi-member set. A multi-member set is represented in the Master File exactly like a common owner set. The fact that the two relationships are based on the same set is stated in the Access File.

For example, to describe the COVERAGE record type and its three members of the COVERAGE-CLAIMS set, you may choose one of four ways as depicted in the following diagram:

1. The first panel shows the COVERAGE record type, owner of the multi-member set, as the root segment. Since several instances of CLAIMS can be reported against one insurance policy (COVERAGE), each member is a non-unique descendant.
2. The second panel depicts HOSPITAL-CLAIM as the parent of COVERAGE, and the other two member record types as descendants of COVERAGE. In each case, a claim can be reported against only one insurance policy. This explanation applies to panels 3 and 4 as well.



Bill-of-Materials

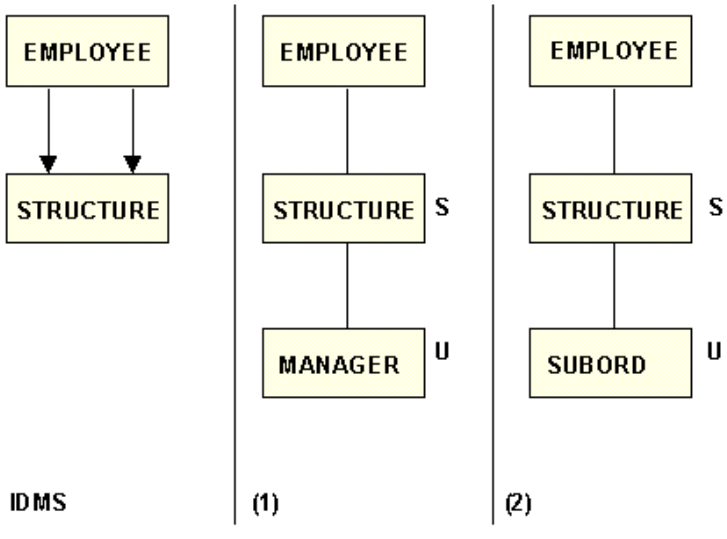
Bill-of-materials structures are classified as simple or multi-tiered. In this section, the simple version is discussed first.

An instance of two record types being linked by more than one set is called a bill-of-materials structure. This structure describes a many-to-many relationship between record occurrences of the same record type. The member record type is the junction record type between the two related owners.

For a simple bill-of-materials structure, the server requires that the owner record type be represented as two or more segments with different field names for the identical fields. This ensures that, at retrieval time, the field names specified in the user's request will provide the proper navigational path.

In the following diagram, the EMPLOYEE and STRUCTURE record types are connected by two sets. This simple bill-of-materials structure can be described two ways:

1. As an employee-to-manager relationship. The EMPLOYEE record type is the parent segment of the non-unique STRUCTURE segment using the REPORTS-TO set. The STRUCTURE record type, in turn, is the parent segment of the unique MANAGER segment using the MANAGES set (the MANAGER segment duplicates the EMPLOYEE segment and its fields are renamed).
2. As an employee-to-subordinate relationship. The EMPLOYEE record type is the parent segment of the non-unique STRUCTURE segment using the MANAGES set. The STRUCTURE record type is the parent segment of the unique SUBORD segment using the REPORTS-TO set (the SUBORD segment duplicates the EMPLOYEE segment and its fields are renamed).



The previous diagram represents a two-tiered employee-to-employee relationship. Multi-tiered relationships are extended bill-of-materials structures. Multi-tiered relationships are created and used for different levels of answer sets. The number of levels or tiers should be kept to a minimum.

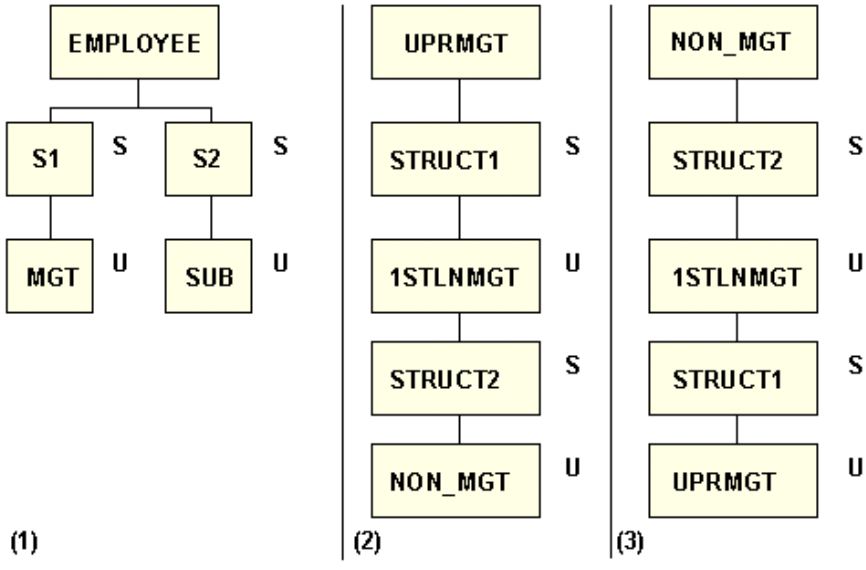
To determine the number of segments required to describe an n-tiered relationship, use this formula:

```
Number of segments = (2 x number of tiers) - 1
```

The following diagram is a three-tiered version of the previous diagram:

1. The first panel combines both views with EMPLOYEE as the parent of two non-unique descendants, S1 and S2. Both S1 and S2, in turn, are parents of a unique descendant, MGT and SUB, respectively (S1 and S2 describe junction records that point to MGT and SUB).

2. The second panel shows a three-tiered relationship between employees implemented in a five-segment single-path hierarchy. The segments UPRMGT (upper management), 1STLNMGT (first-line management), and NON_MGT (non-management) all describe the EMPLOYEE segment but have renamed fields (like S1 and S2 above, STRUCT1 and STRUCT2 contain renamed fields that point to descendant segments).
3. The third panel depicts the opposite of panel 2.

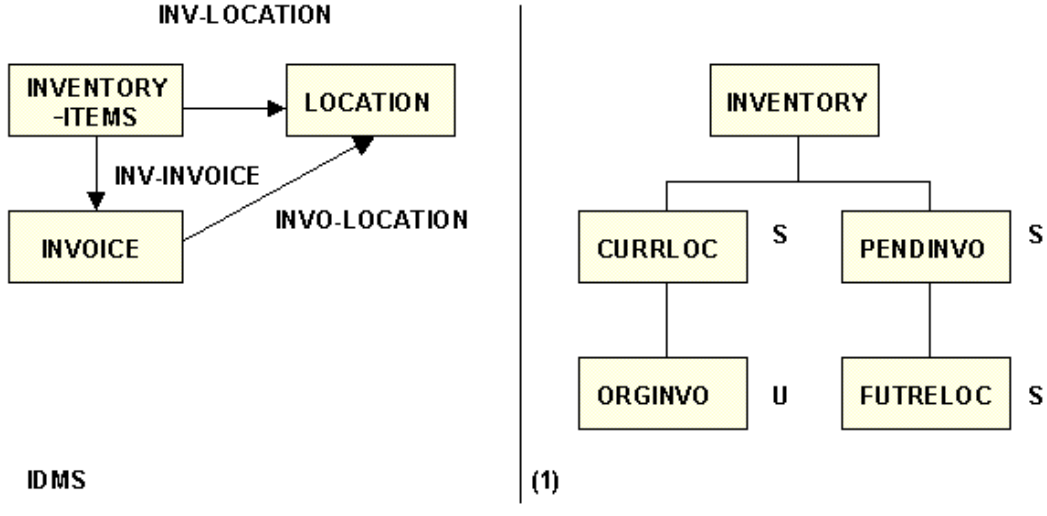


Loop Structures

Loop structures in IDMS/DB implement complicated relationships among record types. For the server depiction of a loop, you must select a record type to be the parent in the relationship.

Suppose you had a loop structure like the one below. An INVOICE record occurrence has an owner record occurrence (INVENTORY-ITEMS) only if the invoice order is pending or has not been delivered. The INVO-LOCATION set lists the location where an invoice item will be or was delivered.

In panel 1 in the following diagram, the server translates this structure as multi-tiered, with one tier of renamed segments. The INVENTORY-ITEMS record type, in this case, acts as the root INVENTORY. The LOCATION record type is mapped as the CURRLOC segment that lists the location of items currently in stock. The INVOICE record type is mapped as the PENDINVO segment that lists pending invoice orders. Segments ORGINVO and FUTRELOC are required segments that rename the data in record types INVOICE and LOCATION. The segment ORGINVO contains historical information for an inventory item. The segment FUTRELOC indicates where an ordered item will be delivered.



CALC-Based and Index-Based Relationships

Logical relationships, unlike physical ones, are based on the occurrence of the same data value in two different record types. To make the parent/descendant connection, the Adapter for IDMS/DB uses CALC fields or indices to locate the related record occurrence(s). The related fields are not required to have the same name in both record types, but the field format must be the same.

Note:

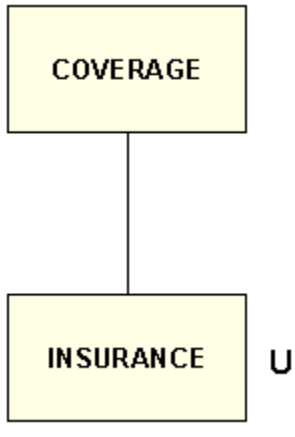
- WHEREs on CALC fields and indices are also used to generate CALC and index calls to IDMS/DB.
- CALC or index fields can also be GROUPNAMEs, consisting of fields contiguous in both parent and descendant segments. The format types and lengths of the GROUP and its fields must be comparable in both parent and descendant segments.

Like set-based descendants, CALC- and index-based descendants are unique or non-unique, but this depends largely on how the DUPLICATES parameter is specified in the Access File (the SEGTYPE parameter for the descendant must also reflect the DUPLICATES parameter; for example, CLCDUP=N, SEGTYPE=U). The server treats unique descendants in the same manner regardless of what underlies the parent/descendant relationship: set, index, or CALC field.

The COVERAGE and INSURANCE-PLAN record types in the diagram in *Set-Based Relationships* on page 898 illustrate a logical relationship. The field PLAN-CODE is common to both record types. The parent/descendant relationship can be described to the server if the:

- INSURANCE-PLAN record type has an index on PLAN-CODE.
- INSURANCE-PLAN record type is an IDMS/DB CALC record type with PLAN-CODE as the CALC key.

The diagram below depicts the server representation of the diagram in *Set-Based Relationships* on page 898 that uses the CALC field method. The server interprets COVERAGE as the parent segment and INSURANCE-PLAN as the descendant. Since the DUPLICATES parameter is set to N (CLCDUP=N), the INSURANCE segment is unique.



Logical Record Facility Concepts

The Adapter for IDMS/DB supports two kinds of LRF-based records:

- Logical Records (LR) are built from network record types. They are not physically stored as such; instead, they are defined within a subschema using DBA-supplied navigational paths. Logical Records are created at execution time from real database records-types based on DBA-supplied navigational paths and the SELECTs passed to LRF from the server.

- Automatic System Facility (ASF) records are created by end-users with the Automatic System Facility, a menu-driven front end to LRF. This Facility generates subschemas and navigational paths based on the user's menu selection.

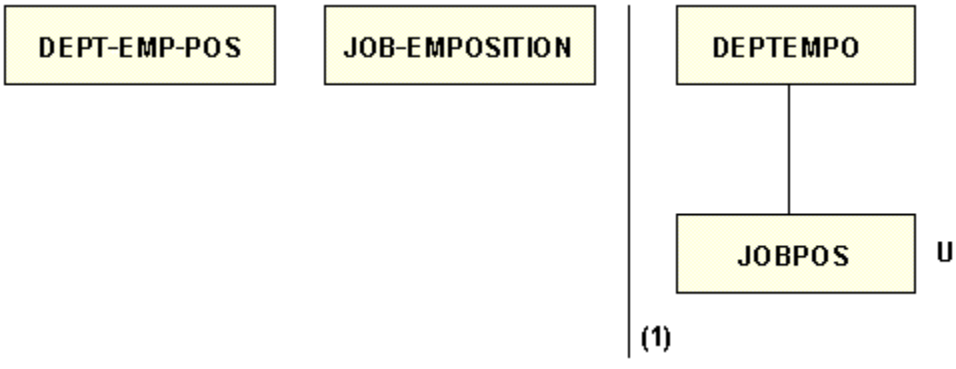
The Adapter for IDMS/DB uses the IDMS/DB Logical Record Facility (LRF) to retrieve and create ASF and LR records. In general, the LRF-based records can contain information from several sources (both DML created and ASF generated) that are located in several database areas. All fields, records, and areas, however, must be defined to the same subschema.

LRF-based records may be related to each other using an embedded cross-reference. Your Master File can list up to 64 related LRF-based records. Access Files can list an unlimited number of subschemas. However, the server accesses up to 16 subschemas per request.

LRF Records as Descendants

With the Adapter for IDMS/DB, you may create a parent/descendant relationship between two LRF records if they share a common field or GROUP. Field lengths and formats must be the same in both segments. The shared fields are specified in the descendant segment declaration of the Access File as the values of the KEYFLD/IXFLD pair.

For example, in the diagram below, the LRF record DEPT-EMP-POS is represented as the root segment DEPTEMPO; the LRF record JOB-EMPOSITION as the unique segment JOBPOS. The related fields are POS_STRT_DR2 (the IXFLD value) and POS_STRT_DT1 (the KEYFLD value).



The restriction that the shared field in the descendant record be a CALC or an indexed field does not apply to LRF records. However, this kind of embedded cross-reference has one restriction: the IDMS/DB path group for an LRF record that acts as the descendant segment must contain a SELECT clause to process the implied WHERE clauses.

Syntax: **How to Implement a Parent/Descendant Relationship With SELECT**

SELECT clauses are maintained by your DBA and should already be available in your subschema. The following SELECT clauses can successfully implement a parent/descendant relationship. They are listed in descending order of efficiency

1. `SELECT FOR FIELDNAME EQ` *`fieldname`*
2. `SELECT USING INDEX` *`indexname`*
3. `SELECT FOR FIELDNAME` *`fieldname`*
4. `SELECT FOR ELEMENT` *`elementname`*
5. `SELECT`

where:

`fieldname`

Is the joined-to IDMS/DB field name on the descendant record type.

`indexname`

Is the index set name to the joined-to field.

`elementname`

Is the physical record type on which the joined-to field is stored.

Note:

- If no specific SELECT clause exists, a null SELECT clause (item 5) must be available to process an answer set.
- LRF records that return partial record occurrences and user-defined path status should not be used. If the adapter encounters a user-defined path status, the status is interpreted as LR-ERROR and the retrieval process is halted with messages EDA967 and EDA949.
- Do not confuse the use of the word SELECT with the SQL SELECT statement. In the above example, the word SELECT is used to refer to the IDMS/DB internal meaning.

Summary of Network Relationships

As illustrated in the previous examples, there are four ways to implement a network relationship. Each can be described as a parent/descendant relationship:

- Owner/member

- Member/owner
- Field or GROUP/CALC field
- Field, GROUP/SPF, or Integrated Index

All four can be intermixed in one Master File. The actual underlying connection (set, CALC, index) between parent and descendant is not apparent to end users who specify field names. In addition, a Master File can list record types from multiple subschemas, databases, and dictionaries.

In server processing, the identity of the record type behind a segment is invisible. The retrieval technique is followed in all cases as if all segments were represented by distinct records. Within IDMS/DB, currencies are maintained by storing the DBKEYs of record types and retrieving the record occurrence again, when needed.

The top-to-bottom order in which segments are defined (the chains of parent/descendant relationships) corresponds to structural relationships among the IDMS/DB record types. This top-to-bottom order is logically significant; the left-to-right order, on the other hand, is not.

Managing IDMS/DB Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the IDMS/DB data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each IDMS/DB file that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

For the Adapter for IDMS/DB to access IDMS/DB files, you must describe each IDMS/DB file you use in a Master File and Access File. The logical description of an IDMS/DB file is stored in a Master File, which describes the field layout.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for IDMS/DB

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Dictionary Name

Type a data dictionary name.

Database Name

Type a database name.

Subschema Name

From the drop-down list of subschemas, select a subschema.

Select Root Record Name and Child Records

1. Choose the first record of the selected subschema to be described and click Add. This record will be the root segment in the generated Master File.

   Note: If a field name contains dashes (-) as part of the name, they are converted to underscores (_) in the generated Master File.

   It is recommended that the root record-type have a set relationship with a CALC or index field.

2. If you want to add additional levels of records to this structure, right-click the record name and then choose Add Child from the pop-up menu. Records that have no available children display a red diamond next to the record name. Those with available children display a stack of green squares.

   A list of available child segments is displayed. Check each record that you want to be a child of the previous record. To select all of the listed records, check the Record Name check box.

3. When you have selected the child records you want to add to the structure, click Add. You can repeat this process of selecting children and creating additional levels in the structure until no children are available.

4. When you are finished selecting children, right-click the record name and choose Save from the pop-up menu.

Application

Select an application directory. The default value is baseapp.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Synonym Name

If necessary, edit the default name for the synonym that will be created.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Master Files for IDMS/DB

This section explains the rules for making an IDMS/DB data source accessible to the server using the Master File. The Access File is an extension of Master File syntax that provides information to map DML record types and LRF-based records, including record and area names and, where needed, set or field name information.

A Master File consists of file, segment, and field declarations. Rules for declarations are:

- Each declaration must begin on a separate line and be terminated by a comma and dollar sign (,$). Text appearing after the comma and dollar sign is treated as a comment.
- A declaration can span as many lines as necessary as long as no attribute=value pair is separated. Commas separate attribute=value pairs.

The following sections summarize the syntax for each type of declaration, and then describe each attribute.

File Attributes

Master Files begin with a file declaration that names the file and describes the type of data source; in this case, an IDMS/DB data source. The file declaration has two attributes, FILENAME and SUFFIX.

Syntax: How to Identify a Master File

```
FILE[NAME]=name, SUFFIX=IDMSR [,$]
```

where:

name

Is any 1- to 8-character name. On z/OS, the Master File is the member name within the PDS allocated to DDNAME MASTER.

IDMSR

Indicates that the Adapter for IDMS/DB is required for data retrieval.

Segment Attributes

Each IDMS/DB segment described in a Master File requires a segment declaration that consists of at least two attributes, SEGNAME and SEGTYPE.

- *SEGNAME*
- *SEGTYPE*
- *PARENT*
- *CRFILE (Cross-referenced File)*
- *OCCURS and POSITION*

SEGNAME

The SEGNAME value assigned to DML record types and LRF records are suggestive names – not necessarily the IDMS/DB record names. The segment name may be a maximum of eight characters and must be unique within a given Master File. If the same IDMS/DB record type is viewed in two different contexts (for example, a loop structure), two segment declarations are required.

SEGTYPE

The SEGTYPE keyword indicates whether a segment occurs once (SEGTYPE=U) or many times (SEGTYPE=S). It is used as follows:

- For a root segment, SEGTYPE has no meaning and may be omitted entirely.
- For a descendant segment, SEGTYPE values can be S or U.
- For descendant segments with set-based relationships, SEGTYPE indicates whether the segment acts as an owner or a member. If the descendant segment is the owner record type, the SEGTYPE value is U. If the descendant is the member, the SEGTYPE value is S.
- For descendant segments with CALC-based or index-based relationships, SEGTYPE values may be S or U depending on the DUPLICATES (CLCDUP or IXDUP) value.
- For descendant segments with LRF-based relationships, SEGTYPE values may be S or U.

PARENT

The PARENT keyword is required for descendant segment declarations. The PARENT value names the descendant's parent segment. This keyword is not specified for the root declaration.

CRFILE (Cross-referenced File)

The CRFILE keyword is specified only for segments that are described remotely in another Master File. The field descriptions for these segments are, in effect, copied into the Master File at execution time. Remote descriptions are discussed in *Remote Descriptions* on page 920.

OCCURS and POSITION

The OCCURS and POSITION attributes are specified only when the segment corresponds to an intra-record structure, such as a COBOL OCCURS or OCCURS DEPENDING clause. These keywords are described in detail in *Intra-record Structures: OCCURS Segment* on page 921.

Field Attributes

Each segment consists of one or more fields. The Master File need not describe all fields from a segment. The attributes are:

- *FIELDNAME*
- *ALIAS*
- *USAGE*
- *ACTUAL*
- *GROUP Fields*
- *IDMS/DB Database Key*

To describe a field in the Master File, you must specify the primary attributes FIELDNAME, ALIAS, USAGE, and ACTUAL. These attributes are discussed in this section. Note that the adapter does not support the MISSING attribute.

FIELDNAME

The FIELDNAME keyword may contain any name, not necessarily an IDMS/DB field name. It can be a maximum of 48 characters. The name that you assign must be unique, because in the server, data is referenced through field names. If the same IDMS/DB record type viewed in different contexts underlies two or more segments, different field names must be specified in separate segment descriptions.

Due to the record-oriented nature of IDMS/DB, the fields are described for each segment in the same order as they appear in the subschema record area. Bytes skipped for field alignment or for fields you want to omit must be described as dummy fields of the appropriate length.

For example, a 1-byte alphanumeric field is followed by a double-precision floating point field:

```
SEGNAME=EMPSTATUS,$
  FIELD=STATUS_CODE,SCODE ,A1,A1,$
  FIELD=            ,     ,A7,A7,$
  FIELD=GROSS_SALES,GSALES,D12.2,D8,$
```

The same name can be used for all dummy fields; in the example above, blanks are used.

You do not need to describe all fields of the record type or LRF record; only an initial set, starting with the first field and continuing up to the last field of interest. For variable-length record types, treat the fixed-length portion as one segment and the variable portion as another segment, as described with the OCCURS attribute. For information about OCCURS segments, see *Intra-record Structures: OCCURS Segment* on page 921.

Syntax: How to Describe a Field in the Master File

```
FIELD[NAME]=field,[ALIAS=]alias,[USAGE=]display,[ACTUAL=]format ,$
```

where:

field

Is a 1- to 48-character field name.

alias

The ALIAS keyword is used for certain fields which require specific ALIAS values.

display

Is the display format for the field.

format

Is the definition of the IDMS/DB field format and length (n).

You can omit the ALIAS, USAGE, and ACTUAL keywords from the field declaration if the values are specified in the standard order (FIELD, ALIAS, USAGE, ACTUAL). For example, the following declarations are equivalent:

```
FIELD = YEAR, ALIAS=, USAGE=A2, ACTUAL=A2,$
FIELD = YEAR, ,A2, A2,$
```

ALIAS

The ALIAS keyword is used for certain fields which require specific ALIAS values:

- Database key fields – the ALIAS value is DBKEY.
- ORDER fields – the ALIAS value is ORDER.
- Fields on LRF-based records (LR or ASF) that correspond to the last fields of their underlying physical record types. Filler fields may be required if the last field does not end on a double-word boundary. The ALIAS for each filler field is a unique name with a maximum of eight characters counting the .END suffix. The adapter uses this suffix to correctly address LRF records for LRF calls.
- GROUP fields – an ALIAS is always required or a message results.

The following is an example of a filler field in a segment that describes an LRF record. Suppose a record called JOB-EMPOSITION is defined to the IDMS/DB subschema with seven fields: the first three fields are derived from a physical (DML) record type called JOB; the last four fields, from the EMPOSITION physical record type. The Master File syntax for this LRF record looks like this:

```
FILENAME=JOBMAST, SUFFIX=IDMSR,$
  SEGNAME=JOBEMP, SEGTYPE=S,$
    FIELDNAME=JOBID       ,ALIAS=          ,USAGE=A4   ,ACTUAL=A4  ,$
    FIELDNAME=TITLE       ,ALIAS=          ,USAGE=A20  ,ACTUAL=A20 ,$
    FIELDNAME=DESCRIPTN   ,ALIAS=CMTS.END ,USAGE=A120 ,ACTUAL=A120,$
    FIELDNAME=START_DTE   ,ALIAS=          ,USAGE=A6YMD,ACTUAL=A6  ,$
    FIELDNAME=FINISH_DTE  ,ALIAS=          ,USAGE=A6YMD,ACTUAL=A6  ,$
    FIELDNAME=SALARY_GRADE,ALIAS=          ,USAGE=P4   ,ACTUAL=Z2  ,$
    FIELDNAME=SALARY      ,ALIAS=          ,USAGE=P10.2,ACTUAL=P5  ,$
    FIELDNAME=            ,ALIAS=FILL.END ,USAGE=A1   ,ACTUAL=A8  ,$
```

In this example, the filler field corresponds to the last field of the EMPOSITION record type, because LRF records must lie on a double-word boundary. The IDMS/DB filler field is stored to make the record length a multiple of 8. IDMS/DB filler fields on physical record types underlying LRF views must become filler fields. These filler fields can have any field name or contain a blank; its ALIAS must include the .END suffix. Since the JOB record type is 144 bytes (total of ACTUAL formats), it does not need a filler; the last field DESCRIPTN only requires an alias with an .END suffix.

USAGE

Master Files require you to specify field formats and lengths for USAGE and ACTUAL parameters.

The USAGE and ACTUAL keywords describe the data format of the field. The USAGE parameter defines the field length for the fields. Allow for the maximum possible number of characters or digits including decimal points. You may include valid edit options without increasing the length size.

Note: For network record types, the USAGE and ACTUAL formats of zoned CALC and zoned index fields must be described as alphanumeric (A).

ACTUAL

The ACTUAL parameter defines the field length for COBOL fields found in the IDMS/DB file. The number of internal storage bytes used by COBOL determines the actual length of the field for these formats:

Alphanumeric (A)	Equals the number of characters described in the PICTURE clause.
Zoned decimal (Z)	Equals the number of characters described in the PICTURE clause.
Integer (I)	Equals 2 or 4, corresponding to decimal lengths of 1-4 or 5-9 in the PICTURE clause.
Floating-point (F)	Equals 4 bytes.
Double-precision (D)	Equals 8 bytes.
Packed decimal (P)	Equals (number of PICTURE digits / 2) + 1; excluding sign (S) or implied decimal (V).

Use the following chart as a guide for describing ACTUAL formats:

COBOL Format	COBOL PICTURE	Bytes of Storage	ACTUAL Format	USAGE Format
DISPLAY	X(4)	4	A4	A4
DISPLAY	S99	2	Z2	P3
DISPLAY	9(5)V9	6	Z6.1	P8.1
DISPLAY	99	2	A2	A2

COBOL Format	COBOL PICTURE	Bytes of Storage	ACTUAL Format	USAGE Format
COMP	S9	4	I2	I1
COMP	S9(4)	4	I2	I4
COMP	S9(5)	4	I4	I5
COMP	S9(9)	4	I4	I9
COMP-1	-	4	F4	F6
COMP-2	-	8	D8	D15
COMP-3	9	1	P1	P1
COMP-3	S9V99	2	P2	P5.2
COMP-3	9(4)V9(3)	4	P4	P8.3
FIXED BINARY(7) (COMP-4)	B or XL1	4	I4	I7

Note:

- For COMP-1 and COMP-2, allow for the maximum possible digits.
- For COBOL DISPLAY fields with zoned decimal, server formats must be packed (P).
- For COMP-1 and COMP-2, PICTURE clauses are not permitted for internal floating-point formats (F and D).

GROUP Fields

The GROUP keyword identifies a set of fields following it with a single name. This GROUP name is any unique name up to 48 characters in length. Its usage is similar to that of a COBOL group name. Generally, this attribute is used for IDMS/DB indexed or CALC fields.

Note:

- USAGE and ACTUAL format types for a GROUP field are always alphanumeric (A).
- USAGE and ACTUAL format lengths for a GROUP field are the sums of the field lengths that form the GROUP field.

For example, a GROUP field called EMP_NAME is composed of two fields, FIRST_NAME and LAST_NAME. Notice the USAGE and ACTUAL formats:

```
GROUP=EMP_NAME    ,ALIAS=  ,USAGE=A25  ,ACTUAL=A25 ,$
  FIELD=FIRST_NAME,ALIAS=  ,USAGE=A10  ,ACTUAL=A10 ,$
  FIELD=LAST_NAME ,ALIAS=  ,USAGE=A15  ,ACTUAL=A15 ,$
```

The FIELDTYPE keyword identifies indexed fields, both SPF and Integrated, on network record types. Omit it for LRF records.

IDMS/DB Database Key

The database key of a network record type corresponding to a segment can optionally be described as the last field in the segment. To specify a database key, use the following values:

Keyword	Description
FIELDNAME	Is any unique key. It can be a maximum of 48 characters.
ALIAS	Value is DBKEY.
USAGE	Value is I10.
ACTUAL	Value is I4.

The database key is used to select records from entry segments when screening on particular IDMS/DB values in the user request.

Remote Descriptions

SEGTYPEs KLU and KL specify unique and non-unique segments for which the aggregate fields are remotely described in another Master File. In other words, a KLU or KL segment contains no field information; its fields are fully defined in another Master File. The CRFILE keyword specifies the source or remote Master File. At execution time, the remote field descriptions are, in effect, copied into the current Master File.

Generally, KLU and KL segment types are used when several Master Files are constructed for the same IDMS/DB subschema. They save typing and maintenance effort. Use KLU if the underlying segment is unique (U); KL if the underlying segment is non-unique (S). Remote descriptions have no logical implications regarding parent/descendant relationships, nor do they impact their implementation.

To specify a remote description, you must give the KLU or KL segment the same name as the source segment in the remote Master File to ensure the proper use of field descriptions. The source file is specified as the CRFILE value. For example:

```
SEGMENT=SALES,PARENT=DEPT,SEGTYPE=KL,CRFILE=RECORDS,$
```

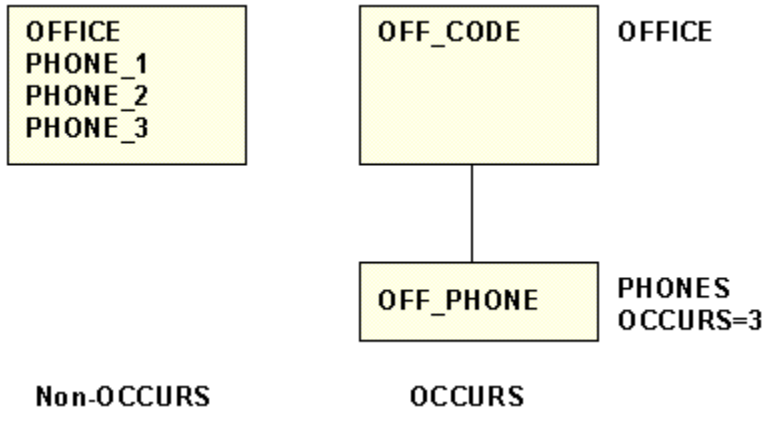
This segment declaration indicates that the field descriptions for the SALES segment are obtained from the SALES segment in the RECORDS Master File. The SEGTYPE for the SALES segment in the RECORDS Master File cannot be KL or KLU; only U or S. Only field names and their attributes from the source file are used; original segment attributes are not. The source file does not have to be a file description as long as it describes the named segment.

Intra-record Structures: OCCURS Segment

A common record structure is one where a field or group of adjacent fields is repeated in the same record type. In COBOL and PL/I syntax, repeating intra-record structures are defined through an OCCURS clause. The server equivalent of an OCCURS clause is an OCCURS segment.

For example, the OFFICE record type contains the field OFFICE-PHONE that occurs three times. The corresponding OFFICE segment can list three separate fields with different field names, or alternately OFFICE-PHONE can be described in a separate descendant OCCURS segment. Using the OCCURS method, each office phone is referenced by a single name (see the Master File for EMPSS01).

The diagram below depicts the non-OCCURS method and the OCCURS method.



OCCURS segments have two attributes or keywords: ORDER and POSITION. The POSITION keyword directs the server to OCCURS segments when non-repeating fields exist between repeating fields. The ORDER keyword creates a fictitious count field that may be decoded.

Describing the Repeating Group to the Server

Any fixed or variable-length record type described in COBOL can be mapped into a server hierarchy using OCCURS segments. A simple OCCURS segment is a descendant of the parent segment which contains non-repeating fields found in the IDMS/DB record type. You must specify the OCCURS keyword on the descendant segment declaration that describes the repeating group. Like the COBOL OCCURS clause, the value of this keyword may be a numeric constant or a field name. The numeric constant indicates a fixed number of repetitions; a field name indicates a count field in the parent segment that maintains a count of the number of occurrences.

OCCURS segments also describe parallel and nested intra-record hierarchical structures. Parallel sets of repeating groups are described as multiple descendant segments of the same parent. In a nested structure, where a repeating group contains another repeating group, one OCCURS segment is the parent of another. Fixed and variable OCCURS segments can be intermixed in any order.

The restrictions for OCCURS segments are as follows:

- The count field for a variably-occurring repeating group must be located physically before the repeating group in the parent of the OCCURS segment.
- A record structure that has a variable number of occurrences but no count field is not within the scope of IDMS/DB.
- The SEGTYPE for an OCCURS segment is specified as S or KL, indicating that it is a non-unique segment.
- OCCURS segments must be defined in the Master File in the same order as they appear in the actual record type, unless the POSITION attribute is used.
- OCCURS segments do not have a corresponding segment declaration in the Access File, because the Adapter for IDMS/DB simulates them using the parent record. OCCURS segments do not generate any additional IDMS/DB calls.

From the server standpoint, OCCURS segments are indistinguishable from other segments. The server processes them, if referenced, in the usual top-to-bottom, left-to-right retrieval order.

For example, consider this COBOL budget record type:

```
01  BUDGET-RCD.
02  ACCOUNT           PIC XXX.
02  ACTUAL-COUNT      PIC 99.
02  PLANNED-AMT       PIC 9(9) OCCURS 12 TIMES.
02  ACTUAL-AMT        PIC 9(9) OCCURS 12 TIMES
                       DEPENDING ON ACTUAL-COUNT.
```

The equivalent Master File is:

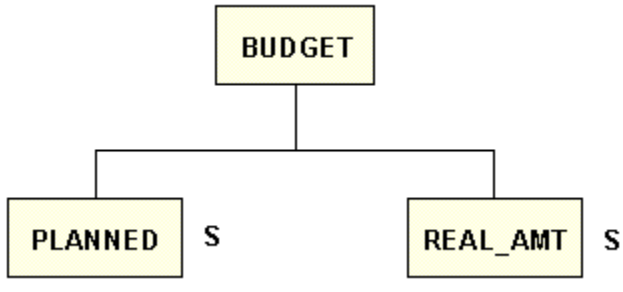
```
SEGMENT=BUDGET,SEGTYPE=S,$
   FIELD=ACCOUNT      ,ALIAS=   ,USAGE=A3  ,ACTUAL=A3       ,$
   FIELD=ACTUAL_COUNT ,ALIAS=   ,USAGE=P4  ,ACTUAL=Z2       ,$

SEGMENT=PLANNED ,PARENT=BUDGET,SEGTYPE=S,OCCURS=12          ,$
   FIELD=PLANNED_AMT  ,ALIAS=   ,USAGE=P12 ,ACTUAL=Z9       ,$

SEGMENT=REAL_AMT,PARENT=BUDGET,SEGTYPE=S,OCCURS=ACTUAL_COUNT,$
   FIELD=ACTUAL_AMT   ,ALIAS=   ,USAGE=P12 ,ACTUAL=Z9       ,$
```

The mapping principle is very simple: the non-repeating field in the record type is described in one parent segment, and the parallel COBOL OCCURS structures are made into descendant OCCURS segments. The OCCURS keyword on the descendant segments specifies either a number (fixed occurrences) or a count field (variable occurrences). In this case, the count field ACTUAL_COUNT is located in the immediate parent segment called BUDGET and is specified on the REAL_AMT descendant segment.

The following is a diagram for this Master File example:



If the PLANNED or REAL_AMT segments had repeating structures, they would in turn be parents of OCCURS segments defined by the same principles. The BUDGET segment could have other non-OCCURS descendants. The PLANNED and REAL_AMT segments might have CALC-based or index-based descendants. However, set-based descendants of this record type would be tied to the BUDGET segment, not to the PLANNED or REAL_AMT segments.

POSITION

OCCURS segments are defined in the same order as they appear in the actual record type. In some cases, COBOL OCCURS clauses are separated by non-repeating fields. The POSITION keyword in a Master File indicates that the repeating fields are located in the middle of non-repeating fields.

The POSITION attribute can only be used for a repeating group with a fixed number of occurrences. This means that the OCCURS attribute of the descendant segment must equal a numeric constant and not a count field.

Suppose the previous COBOL record type looked like this:

```
01  BUDGET-RCD.
02  ACCOUNT         PIC XXX.
02  PLANNED-AMT     PIC 9(9) OCCURS 12 TIMES.
02  ACTUAL-COUNT    PIC 99.
02  ACTUAL-AMT      PIC 9(9) OCCURS 12 TIMES
                    DEPENDING ON ACTUAL-COUNT.
```

Here, the two repeating structures PLANNED-AMT and ACTUAL-AMT are separated by the non-repeating field ACTUAL-COUNT, which clearly belongs to the BUDGET segment. You must indicate in the Master File that the first occurrence of the PLANNED segment will not immediately follow the ACCOUNT field in the BUDGET segment (the PLANNED-AMT field is described in a separate descendant segment). The POSITION keyword accomplishes this task by directing the server to the descendant segment named PLANNED.

The corresponding Master File looks like this:

```
SEGMENT=BUDGET,SEGTYPE=S,$
  FIELD=ACCOUNT      ,ALIAS=   ,USAGE=A3   ,ACTUAL=A3        ,$
  FIELD=PLANNED_SEG1 ,ALIAS=   ,USAGE=A108 ,ACTUAL=A108      ,$
  FIELD=ACTUAL_COUNT ,ALIAS=   ,USAGE=P4   ,ACTUAL=Z2        ,$

SEGMENT=PLANNED ,PARENT=BUDGET,SEGTYPE=S,OCCURS=12,
        POSITION=PLANNED_SEG1                               ,$
  FIELD=PLANNED_AMT  ,ALIAS=   ,USAGE=P12  ,ACTUAL=Z9        ,$

SEGMENT=REAL_AMT,PARENT=BUDGET,SEGTYPE=S,OCCURS=ACTUAL_COUNT ,$
  FIELD=ACTUAL_AMT   ,ALIAS=   ,USAGE=P12  ,ACTUAL=Z9        ,$
```

The POSITION keyword in the PLANNED segment names a field called PLANNED_SEG1 in BUDGET, the immediate parent segment. PLANNED_SEG1 in the parent coincides with the first field of the first occurrence in PLANNED, the OCCURS segment. The REAL_AMT segment does not require a POSITION keyword, because the position of its first occurrence is correctly inferred as following the last described field in the BUDGET segment.

In the previous example, the PLANNED_SEG1 spans all occurrences of the PLANNED segment. As an alternative, 12 individual fields named PLANNED_SEG1 through PLANNED_SEG12 could be described instead in the BUDGET segment. Each individual field would need the appropriate numeric format. Then you could refer to any one of the 12 amount fields by its specific name, or generically through the PLANNED_AMT field. The POSITION attribute can always be used for this purpose, even when it is not required for positioning the first position of an OCCURS segment located in the middle of the record type.

ORDER Field

Sometimes the sequence of fields within an OCCURS segment is significant. For example, each instance of the repeating field may represent one quarter of the year, but the segment may not have a field that specifies the quarter to which it applies.

ORDER is an optional counter used to identify the sequence number within a group of repeating fields. Specify it when the order of data is important. The ORDER field does not represent an existing field in the data source; it is used only for internal processing.

Syntax: **How to Identify an ORDER Field**

The ORDER field must be the last field described in the OCCURS segment

```
FIELDNAME=name, ALIAS=ORDER, USAGE=In, ACTUAL=I4 ,$
```

where:

name

Is any valid field name.

I*n*

Is an integer format.

Note:

- The ALIAS value must be ORDER.
- The ACTUAL format must be I4.
- The ORDER field must be the last field defined in the OCCURS segment.

Example: **Using the ORDER Field in Requests**

In requests, you can use the value of the ORDER field. You can also specify a DEFINE statement in the Master File to translate it to more meaningful values. For example:

```
DEFINE QTR/A3 = DECODE ORDER(1 '1ST' 2 '2ND' 3 '3RD' 4 '4TH');
```

A subsequent request could include:

```
SELECT TOT.TAXES FROM JOBMAST
WHERE QTR = 1
```

or

```
SELECT QTR,BALANCE,INTEREST
```

Access Files for IDMS/DB

An Access File describes the database access information, for example, database number, file number, and descriptor fields.

Note that before you can access a CA-IDMS/DB file, you must first describe it to the server in two files: a Master File, and an associated Access File. A Master File is required to describe the CA-IDMS/DB file in standard server terminology to the Adapter for IDMS/DB. For more information on the Master File, see *Managing IDMS/DB Metadata* on page 910.

An Access File is required to translate a request for network record types and LRF records into the appropriate CA-IDMS/DB Data Management Language (DML) retrieval commands. This file description consists of 80-character records called declarations in comma-delimited format (keyword=value).

An Access File contains three kinds of declarations:

- Subschema
- Segment
- Index

Subschema declarations identify the subschema used, the IDMS/DB release under which the subschema was compiled, the calling mode to be used to retrieve records, and whether a trace is to be produced. Several subschema declarations may be specified in a single Access File. Each subschema declaration is followed by its segment and index declarations. *Subschema Declaration Keywords* on page 927 describes keywords for subschema declarations.

Access File segment declarations indicate the IDMS/DB record information and the parent/descendant relationship for each network record type or LRF record described as a segment in a Master File (Access File segment declarations are not defined for OCCURS segments). Segment declarations can be specified in any order after their corresponding subschema declaration. *Segment Declaration Keywords for Network Record Types* on page 929 and *Segment Declaration Keywords for LRF Records* on page 932 describe segment declarations for network record types and LRF records, respectively.

Index declarations provide information about each IDMS/DB index. They may also be in any order, one for each indexed field described in the Master File, after their corresponding subschema declaration. *Index Declaration Keywords for Network Record Types* on page 934 describes index declarations for network record types.

Access File Syntax

Each declaration consists of a list of keyword and value pairs, separated by commas. The list is free-form and may span several lines; keywords may be specified in any order. Each declaration is completed with a comma followed by a dollar sign ($). For example, this Access File contains three declarations:

```
SSCHEMA=PAYROLL,RELEASE=15,INDEXAREA=PRIMARY-IX-AREA,
    DBNAME=EMPDEMO,DICTNAME=APPLDICT,$

SEGNAME=ACCOUNT,RECORD=PAYREC,AREA=PAY-REGION,
    CLCFLD=EMPLOYEE_ID,CLCDUP=N,$

IXSET=IXREC-SSN,IXAREA=IX-AREA1,IXFLD=PERS_SSN,
    IXDUP=N,IXORD=A,$
```

Blank lines and lines starting with an asterisk (*) in column 1 are treated as comments. Leading and trailing blanks around keywords and values are ignored. Values that contain commas, equal signs, dollar signs, or spaces must be enclosed in single quotation marks.

Subschema Declaration Keywords

If your Master File defines record types and LRF records from multiple IDMS/DB subschemas, the Access File should contain multiple subschema declarations. After each subschema declaration, list its segment and index declarations.

Subschema declarations for DML and LRF subschemas contain the following keywords; certain keywords are optional as explained in the following summary chart.

Keyword	Description
SSCHEMA	IDMS/DB subschema name.
RELEASE	Release of the IDMS/DB software that was used in the last compilation of the subschema. The value can be 10.2, 12, or 12.*x* (where *x* is your release version), 14, or 15.
MODE	Type of IDMS/DB access the adapter is to perform. Specify LR for LR and ASF records; DML is the default value.

Keyword	Description
TRACE	Optional keyword used for debugging purposes. It specifies whether a basic trace of all IDMS/DB calls or a detailed trace of all the parameters passed to IDMS/DB will be displayed. Values can be YES, PARMS, or NO (NO is the default value).
READY	Optional keyword that specifies when an LRF record is built from two or more physical record types located in several database areas. The adapter prepares or readies all the areas of the subschema. Values can be ALL or null or omitted entirely.
DBNAME	IDMS/DB database name from the DBNAME table corresponding to its subschema. It can be used in local or Central Version mode to translate the subschema name into the proper load module(s) for data access.
INDEXAREA	Name of the primary SPF index area. Required for any subschema with SPF indices.

CV Mode Only

Keyword	Description
DICTNAME	Secondary dictionary load area, if the subschema is not located in the primary dictionary or in a load PDS. Remember that ASF subschemas are located in secondary dictionary load areas by default, so if your Access File describes an ASF record, you must specify this keyword.
NODE	Distributed Database Systems (DDS) node location of an IDMS/DB distributed database. The value is the IDMS/DB data dictionary table entry that identifies the DDS node location of an IDMS/DB distributed database. This keyword is required only if DDS is installed at a user site and if the subschema is located in a remote site location.

Keyword	Description
DICTNODE	DDS node location of an IDMS/DB distributed database subschema in a secondary dictionary load area. The value is the IDMS/DB data dictionary table entry that identifies the DDS node location of an IDMS/DB distributed database subschema. This keyword is required only if DDS is installed at the user site and if the subschema is located in a remote site location.

Note: When running using DDS, Central Version must be used. DDS access is not supported in local mode.

Segment Declaration Keywords for Network Record Types

Your use of keywords in segment declarations for DML record types depends on whether the record type contains a CALC key, acts as a descendant segment, or contains an index. The following keywords are common to all segment declarations.

Keyword	Description
SEGNAM	Corresponding Master File segment name of the DML record type.
RECORD	IDMS/DB record type name.
AREA	IDMS/DB area name that contains the record type.

If your record type is CALC (that is, if the record contains a CALC key) include the two keywords below. These keywords are required for all CALC record types, regardless of how their parent/descendant relationships are implemented.

Keyword	Description
CLCFLD	Master File field name of the CALC field.
CLCDUP	Indicates if the CALC field allows duplicates. The value can be Y or N.

Record types are assigned parent/descendant relationships in the server. These relationships are based on sets and CALC or index fields. Keywords for descendant segments follow. Consult your Master File to determine whether a segment is a descendant or parent.

Field	Keyword	Description
	ACCESS	Indicates the relationship that exists between record types. The value CLC or IX specifies an embedded cross-reference based on a CALC or indexed field. The value SET indicates a physical relationship based on a set of pointers.
Set-Based (ACCESS=SET)	SETNAME	Name of the set relating a descendant to its parent.
	SETMBR	Specifies whether the set membership is mandatory/automatic, mandatory/manual, optional/automatic, or optional/manual. This information is used to verify set membership at execution time. To determine the appropriate membership value, check the set label on your Bachman diagram. Values can be MA, MM, OA, or OM.
	GETOWN	Allows or inhibits GET OWNER calls which obtain the owner records from a member record type. If the value is Y, the adapter issues GET OWNER calls to retrieve the owner record in the set when SEGTYPE is U or KLU. If the value is N, GET OWNER calls are inhibited. Specify N only when the set has no owner pointers and long member record chains are apt to occur. When GET OWNER calls are inhibited, the owner record type cannot be a descendant of its member. In other words, if GET OWNER calls are inhibited, SEGTYPE cannot be U or KLU.
	MULTMBR	Indicates whether the set, in which this record type participates, contains more than one member record type. Values can be Y or N.
	KEYFLD	Server field that sequences the set. Select a field from a parent or descendant segment as the value of KEYFLD in the descendant segment declaration.

Field	Keyword	Description
	SETORD	A (ascending) or D (descending) for sorted set sequence. This keyword is required.
	SETDUP	Y or N if duplicates are allowed. Required for sorted sets.
CALC-Based (ACCESS=CLC)	KEYFLD	Provides the search value to read CALC and index fields in descendant segments. These search values are located in parent segment fields. Specify the parent field name for the value of KEYFLD in the descendant segment declaration. The KEYFLD keyword is especially important when the two record types in a parent/descendant relationship are from different subschemas. The record type that acts as the descendant segment is the entry point into the second subschema. It must have a CALC key (CLCFLD) or index set (SETNAME) with ACCESS=CLC or ACCESS=IX, respectively. The descendant segment declaration must also list the KEYFLD value from the parent segment in the first subschema.
Index-Based (ACCESS=IX)	KEYFLD	See above.
	SETNAME	IDMS/DB name of the index set. A corresponding index declaration is required.

Example: Describing One Subschema With Two Segments

This example shows one subschema with two segments that are CALC record types. The INVOICE record type has a set-based relationship with the CUSTOMER record type.

```
SSCHEMA=SAMPSSCH,RELEASE=15,
SEGNAM=CUSTOMER,RECORD=CUSTOMER,AREA=CUSTOMER-REGION,
 CLCFLD=CUST_NUMBER,CLCDUP=N,$
SEGNAM=INVOICE,RECORD=INVOICE,AREA=INVO-REGION,
 CLCFLD=INV_NUMBER,CLCDUP=N,ACCESS=SET,
 SETNAME=CUSTOMER-INVO,SETMBR=MA,GETOWN=Y,MULTMBR=N,$
```

Example: Describing Two Subschemas

The following example shows two subschemas. The INSURANCE-PLAN record type has a CALC-based relationship with the COVERAGE record type.

```
SSCHEMA=EMPSS01,RELEASE=15,
SEGNAM=COVERAGE,RECORD=COVERAGE,AREA=INS-DEMO-REGION,$

SSCHEMA=EMPSS03,RELEASE=15,$
SEGNAM=INSURNCE,RECORD=INSURANCE-PLAN,
 AREA=INS-DEMO-REGION,CLCFLD=INS_PLAN_CODE,CLCDUP=N,
 ACCESS=CLC,KEYFLD=COV_CODE,$
```

If your record type contains an indexed field, you may suppress area sweeps when the segment is used as a point of entry into the database. To prevent area sweeps, specify the optional keyword below on the segment declaration. Only those record instances connected to the specified index field are accessed.

Keyword	Description
SEQFIELD	Master File field name (FIELDTYPE=I) of the index.

Note: This optional keyword requires an index declaration (see *Index Declaration Keywords for Network Record Types* on page 934).

Segment Declaration Keywords for LRF Records

Segment declaration keywords for LR and ASF records are basically the same as those for network (DML) record types. Specified values, of course, differ.

Keyword	Description
SEGNAM	Corresponding Master File segment name of the LRF record.
RECORD	IDMS/DB name of the LRF record.
LR	Value is Y.
AREA	IDMS/DB area name that contains physical record types. Specify READY=ALL on the subschema declaration for more than one area (if fields originate from many areas).

LRF records use embedded cross-references to create parent/descendant relationships. Specify the following keywords for LRF records that act as descendant segments:

Keyword	Description
ACCESS	Value is LR.
KEYFLD	Master File field name found in the parent.
IXFLD	Master File field name found in the descendant.

The KEYFLD and IXFLD keywords are required to implement parent/descendant relationships. The KEYFLD keyword specifies a field from the parent segment that provides search values. The value of IXFLD, in turn, is a field in the descendant segment that contains equivalent values for KEYFLD. Any field may be selected for IXFLD provided that the record possesses a null SELECT clause.

Suppose your Master File for one subschema contained two LRF records that act as parent and descendant segments:

```
FILE=DEPTEMP,SUFFIX=IDMSR,$
SEGNAME=DEPTEMP,$
 .
 .
 .
 FIELD=EMP_ID      ,ALIAS=   ,USAGE=A4 ,ACTUAL=A4,$
SEGNAME=EMPJOB,  PARENT=DEPTEMP,  SEGTYPE=S,$
 FIELD=EMPLOYEE_ID ,ALIAS=   ,USAGE=A4 ,ACTUAL=A4,$
 .
 .
 .
```

The common field is EMPLOYEE_ID; its field format is the same in both segments. The EMPJOB segment is the descendant of DEPTEMP. The descendant segment declaration in the Access File below contains KEYFLD and IXFLD values:

```
SSCHEMA=EMPSS06,RELEASE=15,MODE=LR,READY=ALL
  DBNAME=EMPDEMO,DICTNAME=APPLDICT,$

SEGNAM=DEPTEMP,RECORD=DEPT-EMPLOYEE,
  AREA=EMP-DEMO-REGION,LR=Y,$

SEGNAM=EMPJOB,RECORD=EMPLOYEE-JOB,
  AREA=ORG-DEMO-REGION,LR=Y,
  ACCESS=LR,KEYFLD=EMP_ID,IXFLD=EMPLOYEE_ID,$
```

If the EMPJOB segment (EMPLOYEE-JOB record) belonged to a different subschema, the Access File example above would include another subschema declaration positioned between the two segment declarations.

Index Declaration Keywords for Network Record Types

The Adapter for IDMS/DB supports two indexing schemes: the traditional method of indexing, using the Sequential Processing Facility (SPF), and IDMS/DB Integrated Indexes. Under SPF, index entries are stored in separate index areas. As of IDMS/DB Release 10, indexes may be integrated with the Database Management System (DBMS).

The following keywords apply to declarations for both SPF and Integrated Indexes. For an example of an index declaration, see *Access File Syntax* on page 927.

Keyword	Description
IXSET	IDMS/DB setname of the index set.
IXFLD	Corresponding Master File field name with FIELDTYPE=I.
IXDUP	Indicates if duplicate index values are allowed. Value can be Y or N.
IXORD	Indicates the sort order of the index. Value can be A (ascending) or D (descending).
IXAREA	IDMS/DB area name of the index; usage varies, see below.

Note:

- This declaration is not used in LRF Access Files.
- For subschemas with SPF indexing, the IXAREA keyword is required.
- For subschemas with Integrated Indexes, the IXAREA keyword is omitted unless the index entries reside in a different area from the record type being indexed.
- A non-unique descendant with an SPF index may not have descendants (immediate or several levels removed) that are related to the same index. This is due to the lack of an IDMS/DB command, which would restore currency after it has been disturbed by the record retrieval of a descendant segment. This restriction does not apply to SPF unique descendants or Integrated Index descendants.

IDMS/DB Sample File Descriptions

The following sections contain:

- The *Schema: EMPSCHM*.
- A *Network Subschema: EMPSS01* for the schema EMPSCHM, plus corresponding *Master File for Network* and *Access File for Network*.
- An *LRF Subschema: EMPSS02* for the schema EMPSCHM, plus corresponding *Master File for LRF* and *Access File for LRF*.
- A sample of a NULL SELECT clause that creates an *Sample of a Partial LRF Record*.
- A sample from a subschema that contains *SPF Indexes*.

Note: Some samples are annotated to illustrate specific clauses.

Schema: EMPSCHM

This schema is the physical description of the IDMS/DB EMPSCHM database. It contains the following items:

- Area-to-file and area-to-DDNAME mapping.
- A CALC-based record.
- A VIA-based record.
- A sorted set ordered by the SKILL-LEVEL field.
- A sorted set ordered by Integrated Indexes using the SKILL-LEVEL field.
- An Integrated Index set ordered by the SKILL-NAME field.

LRF Subschema: EMPSS02

This subschema shows the LRF view of the schema EMPSCHM. It contains the following items:

- Physical record types that are used to create logical records.
- A SELECT clause for CALC access.
- A SELECT ELEMENT clause.
- A SELECT NULL clause.
- A SELECT INDEX clause.

```

Access File for LRF

This Access File is associated with LRF subschema EMPSS02, and corresponds to its Master File.

```
SSCHEMA=EMPSS02,RELEASE=15,MODE=LR,TRACE=PARMS,READY=ALL,$
SEGNAM=DEPTEMPO,RECORD=DEPT-EMP-POS,AREA=EMP-DEMO-REGION,LR=Y,$
SEGNAM=JOBPOS,RECORD=JOB-EMPOSITION,AREA=ORG-DEMO-REGION,LR=Y,
 ACCESS=LR,KEYFLD=POS_STRT_DT1,IXFLD=POS_STRT_DT2,$
```

Sample of a Partial LRF Record

The following is an example of a NULL SELECT clause that creates a partial record by returning a user-defined record code. The adapter does not support this user-defined code or any status code other than LR-FOUND or LR-NOT-FOUND.

```
SELECT
   OBTAIN EACH JOB WITHIN ORG-DEMO-REGION
   IF JOB-EMPOSITION IS NOT EMPTY
     ON 0000 RETURN NO-POS-FOR-JOB
   OBTAIN EACH EMPOSITION WITHIN JOB-EMPOSITION.
```

SPF Indexes

The following is a section of a subschema that contains SPF indexes. Comparable Integrated Indexes are found in the LRF subschema EMPSS02 listed as EMP-NAME-NDX, JOB-TITLE-NDX, and SKILL-NAME-NDX.

```
ADD SET NAME IS IX-EMP-LNAME
  ORDER IS SORTED
  MODE IS CHAIN
  OWNER IS IXOWNER
     NEXT DBKEY POSITION IS AUTO
  MEMBER IS EMPLOYEE
     NEXT DBKEY POSITION IS AUTO
     OPTIONAL MANUAL
     ASCENDING KEY IS ( EMP-LAST-NAME-0415)
          DUPLICATES LAST
.

ADD SET NAME IS IX-TITLE
  ORDER IS SORTED
  MODE IS CHAIN
  OWNER IS IXOWNER
     NEXT DBKEY POSITION IS AUTO
  MEMBER IS JOB
     NEXT DBKEY POSITION IS AUTO
     OPTIONAL MANUAL
     DESCENDING KEY IS ( TITLE-0440 )
          DUPLICATES NOT ALLOWED
.

ADD SET NAME IS IX-SKILL-NAME
  ORDER IS SORTED
  MODE IS CHAIN
  OWNER IS IXOWNER
     NEXT DBKEY POSITION IS AUTO
  MEMBER IS SKILL
     NEXT DBKEY POSITION IS AUTO
     OPTIONAL MANUAL
     ASCENDING KEY IS ( SKILL-NAME-0455 )
          DUPLICATES NOT ALLOWED
    .
```

File Retrieval

The Adapter for IDMS/DB retrieves the necessary records that fulfill a request. It uses information from the following sources to choose the most appropriate and efficient retrieval method:

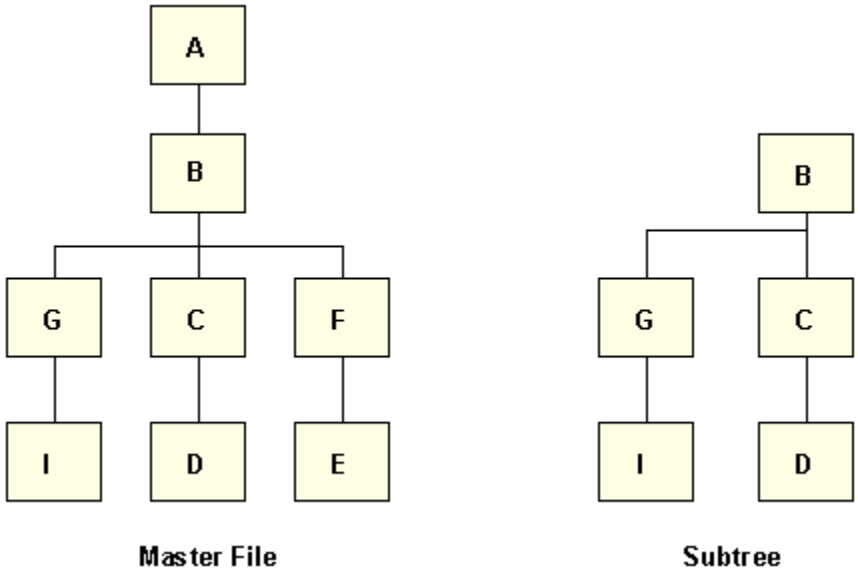
The server uses the Master File to select segments and retrieve data from them.

Note: Sections pertaining to unique segments discuss rules that apply regardless of whether the unique segment is the owner of its parent or is related to its parent through a CALC field, index, or LRF field.

Retrieval Subtree

To retrieve records for a request, the server first constructs a smaller subtree structure from the structure defined by the Master File. The subtree consists of segments that contain fields named explicitly in the request and those named implicitly by DBA DEFINE or COMPUTE statements. The subtree also includes any segments needed to connect these segments.

For example, if an SQL request needs fields from segments D, G, and I, the server constructs the subtree diagram shown below. Segments C and B do not contain fields needed for the request, but they are included in the subtree to connect segment I with segments D and G. Since the segments are descendants of segment B, the entry or root segment of the subtree is segment B. The Master File root segment A is not included, because its fields are not referenced; the records corresponding to segment B can be obtained independently of A. However, if segment B were an OCCURS segment, the IDMS/DB calls would be issued for segment A to obtain information for B.

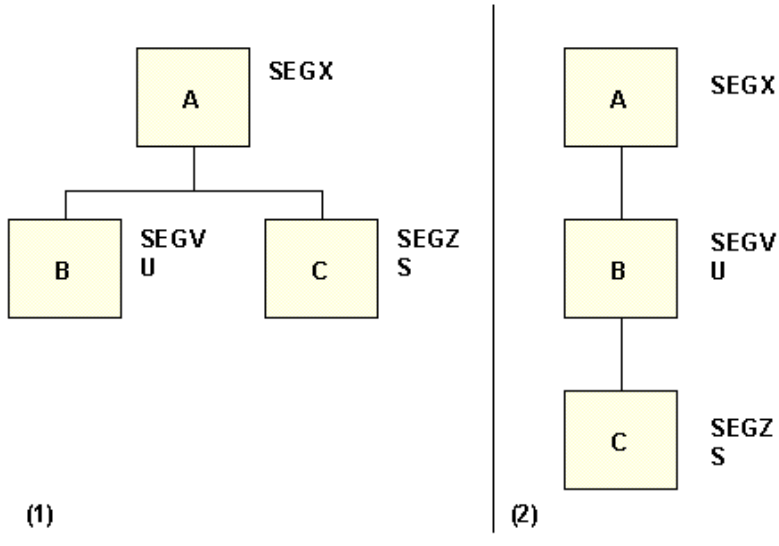


Retrieval Sequence With Unique Segments

The retrieval sequence for subtrees containing unique segments is still top-to-bottom, left-to-right, but the unique segments are treated as extensions of their parents. Records in a unique segment correspond one-to-one with the records in a parent. Records in a non-unique segment have a one-to-many correspondence. In cases where the parent segment has unique and non-unique descendants, the unique descendants are always retrieved first regardless of the left-to-right order.

A retrieval view shows which sort and WHERE clauses are valid. For sort statements (BY or ACROSS), the segment containing the sortfield must lie on the same path as the segments with all requested fields. That is, the segment with the BY or ACROSS field must be an ancestor or descendant of the segments containing the required fields.

For instance, panel 1 of the following diagram shows two descendant segments. The statement SELECT B ORDER BY C is invalid, because the segments containing fields B and C do not lie on the same path. However, if the segment containing B is a unique segment, the two segments do lie on the same path. Panel 2 shows the retrieval view. The statement SELECT B ORDER BY C is valid.



The retrieval sequence for unique segments may also affect the results of an SQL statement that contains COUNT or SUM. If a segment is the parent of a unique descendant, there is a one-to-one relationship. A COUNT statement, such as COUNT A AND B, returns identical results for each field, because the same record A is counted several times for each record B. If the parent/descendant relationship is reversed with a non-unique parent, the result for field A is a greater number than the result for field B.

Screening Conditions

If a record in a segment fails a WHERE condition, the server does not retrieve the corresponding records in descendant segments. Suppose this request is entered against the structure EMPSS01 (corresponding Master File is EMPFULL).

```
SELECT EMP_ID,OFF_CODE
FROM EMPFULL
WHERE DEPT_NAME = 'PERSONNEL'
ORDER BY OFF_CODE
```

Every time a record in segment DEPT has a value in the DEPT_NAME field not equal to PERSONNEL, the server ignores the corresponding records in descendant segments EMPLOYEE and OFFICE, and retrieves the next record in segment DEPT. In addition, when a WHERE clause on a lower segment fails, the row is removed from the server answer set.

To increase I/O efficiency, place the WHERE clauses at a higher level in the file structure. This restricts the number of records the server has to test. The example below shows the benefits of two WHERE clauses versus one.

Assume a subtree has four segments:

- DEPT contains department IDs and information.
- EMPLOYEE contains employee names and IDs.
- EMPOSIT contains the positions that the employee has held.
- JOB contains a list of jobs offered by the company.

To list all employees who are programmer/analysts:

```
SELECT TITLE,DEPT,LAST_NAME,FIRST_NAME
FROM EMPFULL
WHERE TITLE = 'PROGRAMMER/ANALYST'
ORDER BY DEPT,LAST_NAME,FIRST_NAME
```

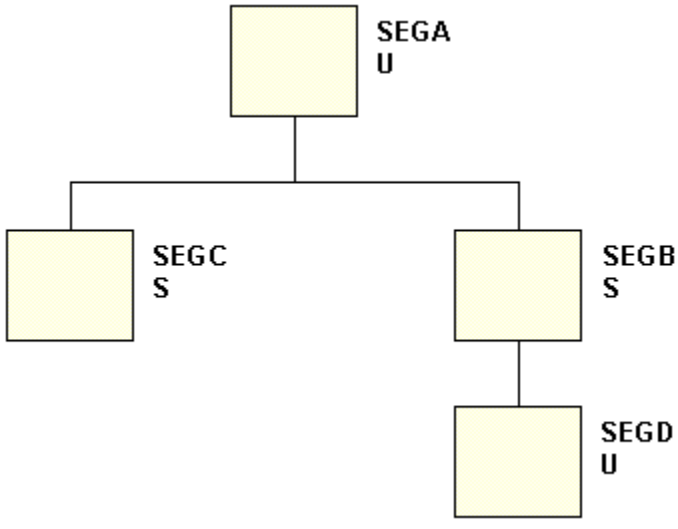
For this request with only one WHERE clause, the server retrieves each DEPT record, each EMPLOYEE record for a given DEPT, each EMPOSIT record for a given EMPLOYEE record, and the JOB record connected to each EMPOSIT. After retrieval, the server determines whether to include in the answer set the record from the value of the TITLE field. To make retrieval more efficient, add another WHERE clause on a segment higher in the structure. In this company, only the Internal Software department has programmer/analysts working for it:

```
SELECT TITLE,DEPT,LAST_NAME,FIRST_NAME
FROM EMPFULL
WHERE DEPT_NAME = 'INTERNAL SOFTWARE'
WHERE TITLE = 'PROGRAMMER/ANALYST'
```

Now the server retrieves and tests records only when the DEPT_NAME field equals the value INTERNAL SOFTWARE.

Screening Conditions With Unique Segments

If a record in a unique segment fails a WHERE test, the server rejects its parent and retrieves the next record of the parent segment. For example, in the following diagram, if a record in non-unique segment C fails a WHERE clause, the server retrieves the next record in segment C. Only if all C records for a given A fail the test is the A record rejected. When a record in unique segment D fails a test, the server rejects the parent B record and retrieves the next record in segment B. When a record in the entry A segment fails a test, the server retrieves the next A record, even if the entry segment is defined as unique.



Short Paths

When the server retrieves a record in a parent segment, it retrieves the corresponding records in the descendant segment. If descendant records do not exist, the processing of the parent record and whether it is included in an answer set depends on whether the descendant segment is unique or non-unique.

Short Paths in Unique Descendants

For a unique descendant with a missing record, the server creates a temporary record to replace the missing record. The temporary record contains fields with default values: blanks for alphanumeric fields and zeroes for numeric fields.

For example, an EMPLOYEE segment with the field EMP_NAME has a unique descendant OFFICE segment with the field OFF_CITY. The field OFF_CITY indicates the location of an employee office. Gary Smith does not work out of an office location, so he has no OFFICE record. In this situation, all requests that refer to OFF_CITY display blank spaces for the entry GARY SMITH.

Short Paths in Non-Unique Descendants

For a non-unique descendant segment with a missing record, the server rejects the parent instance and retrieves the next parent instance.

Syntax: How to Specify Short Paths in Non-Unique Descendants

For a non-unique descendant segment with a missing record, the results depend on how the ALL parameter is set:

```
SET ALL = {ON|OFF}
```

where:

`ON`

The parent record is processed provided that there are no screening conditions on fields in the descendant segment. Missing data is usually indicated on the report by the default NODATA character (.).

`OFF`

The parent instance is rejected and the next parent instance is retrieve. OFF is the default value.

Note: SET ALL = PASS is *not* supported by the adapter.

Record Retrieval

To obtain all of the necessary records to fulfill a request, the Adapter for IDMS/DB navigates the IDMS/DB database using DML or LRF commands. The adapter automatically generates DML or LRF commands based on information from the Master File, Access File, and your request for the most appropriate and efficient IDMS/DB retrieval method.

There are three kinds of IDMS/DB access:

- *Entry Segment Retrieval of Network Records*.
- *Descendant Segment Retrieval of Network Records*.
- *LRF Record Retrieval* (LR and ASF).

Subsequent sections discuss the navigational strategies used for each kind of access.

Entry Segment Retrieval of Network Records

The server constructs a retrieval subtree based on the Master and Access Files and your request. The root of this subtree is called the entry segment, because the server begins its retrieval search of the database at that point. The actual IDMS/DB retrieval calls used on the entry segment depend on the entry segment's Access File information and any WHERE clauses. To perform the most efficient record retrieval on the entry segment, the adapter chooses one of the following techniques:

- *Retrieval by Database Key*
- *Retrieval by CALC Field*
- *Retrieval by Index*
- *SEQFIELD Parameter*
- *Retrieval by Area Sweep*

These techniques are listed in descending order of efficiency. The idea behind selection logic is to perform as many WHERE clauses as possible at the IDMS/DB level. This minimizes the actual I/O operations required to access the necessary data. Area sweeps are the least desirable retrieval technique, because they read through every record type in the named area, including record types that correspond to other segments, and return every entry segment record to the server. At this point, the server selects those records that satisfy the request's test criteria and discards the rest.

Retrieval by Database Key

The IDMS/DB database key method of retrieval takes precedence over the other methods because it is the most efficient. This method depends on the existence of two conditions:

- A field that corresponds to the IDMS/DB database key (ALIAS=DBKEY) for the entry segment.
- An equality test in the request on the DBKEY field.

The equality test sets the field name of the DBKEY from the entry segment in the Master File equal to a specified numeric value(s):

```
WHERE field = 'value1'
```

Retrieval by CALC Field

If there is no WHERE clause on the DBKEY for the entry segment, the second choice is CALC access. Retrieval through the CALC key, while not as efficient as DBKEY access, takes precedence over an index or area sweep retrieval.

The CALC retrieval method depends on the existence of two conditions:

- The entry segment must contain a CALC keyfield as specified in the Access File.
- A fully qualified equality test in the request on the CALC field.

The WHERE clause sets the field name of the CALC key for the segment equal to fully qualified values:

```
WHERE field = 'value1'
```

For each value specified in the WHERE clause, the adapter calls IDMS/DB with the following DML command:

```
OBTAIN CALC record
```

If the Access File indicates duplicate records (CLCDUP=Y), each DML call is followed by subsequent calls:

```
OBTAIN DUPLICATE record
```

This ensures that all appropriate records are obtained to satisfy the request.

Retrieval by Index

If there is no DBKEY or CALC key test criteria in the request, the adapter selects the index retrieval method.

Note: An index field must be defined with the FIELDTYPE=I attribute in the Master File and a corresponding index declaration must exist in the Access File.

Index retrieval is performed using:

- WHERE clauses for an indexed field or GROUP in the entry segment.
- The optional parameter SEQFIELD in the Access File segment declaration.

The first method requires at least one WHERE clause that specifies the field name of the index field. The following WHERE clause invokes index-based retrieval:

- Fully qualified.

  ```
  WHERE = 'PROGRAMMER/ANALYST'
  ```

- Partially qualified (generic), also called masking. This applies to alphanumeric fields only.

```
WHERE TITLE LIKE 'PROGRAMMER%'
```

- Specified as a range of values.

```
WHERE TITLE BETWEEN 'PROGRAMMER' AND 'WORD PROCESSOR'
```

When two or more WHERE clauses in a request qualify an index on the entry-level segment, fully qualified retrieval takes precedence over generic; generic retrieval takes precedence over range. If two WHERE clauses are the same type, the index in the first WHERE clause is used. All types of WHERE clauses are also supported for indices that allow duplicate values.

If the test criteria indicates index retrieval, the adapter issues this DML command to IDMS/DB:

```
OBTAIN FIRST record WITHIN setname USING value
```

In this command, *setname* is the name of the index set specified in the Access File.

Then, if the Access File indicates duplicate records, the adapter issues this DML command for index sets:

```
OBTAIN NEXT record WITHIN setname
```

The above OBTAIN NEXT call is issued until all the duplicate records are retrieved. This same NEXT call is also issued if your request contains generic or range WHERE clauses. It is performed once for every value or range specified in the WHERE clause.

Note: If the IXORD parameter is improperly specified in the Access File, a range WHERE clause may erroneously produce an answer set with one or no records.

SEQFIELD Parameter

The second method of index retrieval does not require WHERE clauses, and yet prohibits area sweeps on entry segments. To use this method, add the optional SEQFIELD parameter to the Access File and specify the name of the indexed field as the value of SEQFIELD.

When your request does not contain a WHERE (for DBKEY, CALC key, or another index) and a SEQFIELD is specified for the entry segment, the adapter issues this DML command to IDMS/DB:

```
OBTAIN FIRST record WITHIN setname
```

In this command, *setname* is the IDMS/DB set name of the indexed field (IXSET parameter) from the Access File.

The adapter then issues the next command until all records connected to the index set are retrieved:

```
OBTAIN NEXT record WITHIN setname
```

If no sort criteria (ORDER BY) is specified in the request, the answer set is produced in ascending or descending index set order.

The SEQFIELD method is recommended for indexed segments in large IDMS/DB databases where only a small percentage of record occurrences in a given area are the record types defined by the segments. In such cases, IDMS/DB resource utilization can be greatly reduced through the use of this parameter.

Note: If the index set connection is not mandatory/automatic (MA), some of the records in this record type may not be accessed if it is the entry segment. In this situation, only records that are members of the index set are supplied to the server. If this retrieval result is undesirable, you should omit the SEQFIELD parameter.

Retrieval by Area Sweep

An area sweep is the least efficient method of entry-level retrieval, because it reads through every record in an IDMS/DB area to return records of a given record type. Despite its inefficiency, an area sweep is sometimes the only method available for retrieval.

The adapter performs an area sweep if one of the following occurs:

- No equality WHERE on the DBKEY for the root exists.
- No equality WHERE on the CALC key for the root exists.
- No equality or range WHERE on an indexed field exists.
- No SEQFIELD parameter is specified.

If one of the above situations occurs, the adapter issues this DML command to IDMS/DB:

```
OBTAIN FIRST record WITHIN areaname
```

In this command, *areaname* is the name of the IDMS/DB database area specified in the Access File. Next, the adapter continues to issue this command until all the records are obtained:

```
OBTAIN NEXT record WITHIN areaname
```

Descendant Segment Retrieval of Network Records

To retrieve records from a descendant segment, the adapter's navigational strategy depends on Access File parameters and the SEGTYPE parameter in the Master File. In a few cases, the WHERE clauses in a request also affect the strategy.

In general, the ACCESS parameter in the Access File determines retrieval strategy, because it indicates how parent/descendant relationships are implemented. There is a retrieval strategy for each kind of relationship:

- *Set-Based Retrieval*
- *CALC-Based Retrieval*
- *Index-Based Retrieval*
- *LRF Record Retrieval*
- *Overriding DBNAME and DICTNAME*

Set-Based Retrieval

For a set relationship (ACCESS=SET), the IDMS/DB set is searched starting with the owner to obtain related member record(s). Set relationships are physical ones, implemented by set pointer chains. The SEGTYPE parameter in the Master File indicates whether the descendant segment is unique or non-unique.

If the descendant segment is non-unique (SEGTYPE=S), it represents a member record type. For non-unique descendants, the adapter issues this command:

```
OBTAIN NEXT record WITHIN setname
```

This command is repeated until IDMS/DB indicates that the end of the set is reached. Then the adapter obtains records of other descendant segments for the same parent segment. If no other descendant segments exist, the next parent record is retrieved.

If the descendant segment is unique (SEGTYPE=U), it represents an owner record type. For unique descendant segments, the adapter issues this command:

```
OBTAIN OWNER WITHIN setname
```

The command is issued once, since there is one owner per set. The adapter continues to retrieve descendant records for the same parent or retrieves the next parent record.

The KEYFLD and MULTMBR parameters in the Access File also affect retrieval for certain requests. For a sorted set, the KEYFLD parameter specifies that the set is ordered by a specified field. When the request references a field from the parent segment and has a WHERE (=, BETWEEN, >, >=, <, <=) on the sortfield, the adapter sends this command to IDMS/DB:

```
OBTAIN record WITHIN setname USING value
```

If there are duplicate records (SETDUP=Y), the adapter issues this command:

```
OBTAIN NEXT record WITHIN setname
```

When the value of the sortfield changes beyond the specified range, retrieval for that segment stops. I/O operations are minimized when the sortfield value is supplied in the OBTAIN command.

Note: The means of implementing the sorted set (the traditional method or using IDMS/DB Integrated Indices) is transparent to the adapter.

The MULTMBR parameter indicates an IDMS/DB multi-member set. When it is specified, the adapter searches for other member record types (segments) in the Access File with the same setname. As a result, all necessary IDMS/DB areas are activated.

CALC-Based Retrieval

CALC-based relationships (ACCESS=CLC) are performed with embedded cross-references. A field in the parent segment corresponds to the CALC field in its descendant segment. The adapter uses the value from the parent field and performs entry-level IDMS/DB retrieval. The process of retrieving records from a descendant segment is similar to that of an entry segment. The difference is that the value supplied by the parent segment acts as the WHERE clause as if it were an explicit WHERE.

After the adapter retrieves the host field value (KEYFLD=value) from the parent segment, it calls IDMS/DB:

```
OBTAIN CALC record
```

Then, if the descendant segment is non-unique (SEGTYPE=S), the adapter issues this command until all of the appropriate records are obtained to satisfy the request:

```
OBTAIN DUPLICATE record
```

Note: If the CLCDUP parameter does not correspond to the SEGTYPE parameter, message EDA919 displays.

A descendant segment with a CALC-based relationship (ACCESS=CLC) may act as a parent and be related to its descendants using set-, CALC-, or index-based relationships.

Index-Based Retrieval

Like CALC-based relationships, index-based relationships (ACCESS=IX) also use embedded cross-references. In index-based relationships, the field in a descendant segment represents an index on the IDMS/DB record type. The index can be either a Sequential Processing Facility (SPF) index or an Integrated Index. The adapter uses the value from the parent segment and performs entry-level IDMS/DB retrieval by searching the index set. The process of retrieving records from a descendant segment is similar to that of an entry segment. The difference is that the value supplied by the parent segment acts as the WHERE clause, as if it were an explicit WHERE.

After the adapter retrieves the host field value (KEYFLD=value) from the parent segment, it calls IDMS/DB:

```
OBTAIN FIRST record WITHIN setname USING value
```

Then, if the descendant segment is non-unique (SEGTYPE=S), the adapter issues the following command until all indexed records with the host value are retrieved:

```
OBTAIN NEXT record WITHIN setname
```

Note: If the IXDUP parameter does not correspond to the SEGTYPE parameter, message EDA919 displays.

Only a descendant segment with an Integrated Index may act as a parent and be related to its descendants using set-, CALC-, or index-based relationships.

LRF Record Retrieval

To retrieve LR and ASF records, the adapter sends LRF calls to an access module IDMS/DB which invokes the Logical Record Facility program.

LRF-based records are retrieved when the Access File specifies MODE=LR in the subschema declaration and the adapter constructs an LR call to IDMS/DB with explicit or implicit WHERE clauses from the request. The LRF processes the request as generated by the adapter, selects the appropriate LR path, and constructs each flat view using the full set of WHERE clauses. The process is highly efficient in terms of I/O; only those records which pass the WHERE clause are passed back to the adapter from IDMS/DB.

The retrieval process for LRF records is identical to that of network record types, but the Logical Record Facility maintains its own navigational information for the database, selects the retrieval strategy most appropriate for a given request, and maintains its own set of occurrences.

When the subschema mode is Logical Record (MODE=LR), the adapter analyzes the request and creates an LRF command to be sent to the Logical Record Facility. The LRF command has two formats. The first format is for an entry segment without WHERE clauses:

```
OBTAIN NEXT record
```

The second format is for an entry with WHERE clauses or for a descendant segment:

```
OBTAIN NEXT record WHERE expression1 [AND expressionN]
```

As indicated by the brackets, this command is also used to pass compound WHERE clauses to IDMS/DB.

IDMS/DB processes the adapter call and returns a record if two conditions are met:

- There is a SELECT path in the LR path-group that can process the particular request.

  Note: For entry segments without WHERE clauses, there must be a null SELECT clause defined for the logical record. If there is no available SELECT path, IDMS/DB returns message 2041, and the adapter terminates its processing with an EDA949 message.

- There is a complete LRF record created by the path-group logic. If the selected path-group can return partial records, the adapter processes returned records until the first partial record is returned and the LR status field is not LR-FOUND or LR-NOT-FOUND. When the adapter encounters any other status in the LR status field, it aborts the record retrieval process and returns messages EDA967 and EDA949. Logical records that allow for retrieval of partial records should not be used with the adapter.

The adapter continues to call IDMS/DB for LRF records that correspond to a segment until IDMS/DB returns LR-NOT-FOUND in the LR status field. Then the adapter retrieves records for other segments, or it terminates retrieval and the answer set is produced.

Overriding DBNAME and DICTNAME

You can dynamically override the DBNAME and DICTNAME parameters within the Access File. This allows you to specify the DBNAME and DICTNAME for all IDMS/DB Master File and Access File pairs during a session by using a SET command, eliminating the need to modify each Access File manually.

To override the DBNAME and DICTNAME, issue the SET commands outlined below. Once the SET commands are issued, the DBNAME and DICTNAME specified will override the same keywords in all Access Files during your session until you end your session or set the DBNAME and DICTNAME to default.

If no SET command is issued, the default behavior is followed.

Reference: Set DBNAME and DICTNAME

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
ENGINE IDMSR SET DBNAME dbname
```

```
ENGINE IDMSR SET DICTNAME dictname
```

where:

dbname

Is the IDMS/DB database name that you want to access.

dictname

Is the IDMS/DB dictionary name that you want to access.

Note: These set commands can be included in any supported server profile.

Syntax: How to Display the Current Settings

To display the settings that are currently in effect, issue the following command from a client application or from a remote procedure:

```
EX EDAEXEC 'ENGINE IDMSR SET ?'
```

Syntax: How to Revert to Original Settings

To revert to original settings in the Access File, issue the following commands in a remote procedure:

```
ENGINE IDMSR SET DBNAME DEFAULT
ENGINE IDMSR SET DICTNAME DEFAULT
```

Syntax: How to Override the DBNAME and DICTNAME in All IDMS/DB Access Files With SYSDIRL

```
ENGINE IDMSR SET DBNAME SYSDIRL
ENGINE IDMSR SET DICTNAME SYSDIRL
```

Customizing the IDMS/DB Environment

Using WebFOCUS, you can customize the IDMS/DB environment by inverting files and joining Master Files.

File Inversion

When you create a Master File, you create a default representation of a hierarchy. Sometimes, however, you may not want to follow the default route to retrieve records. Two such instances might be when:

1. Your IF criteria screen a segment at the bottom of a subtree.
2. You are processing a multi-path report with IF criteria or sort phrases that are not on a common path.

When these situations occur, using WebFOCUS you can specify a new entry segment (root) at execution time for a specific request. This process is called file inversion, because the parent/descendant relationships along the path linking the original root and the new root are reversed; other parent/descendant relationships remain unchanged.

Note: File inversions only change the file views; they do not affect the data.

Syntax: How to Invert a File

```
TABLE FILE filename.field
```

where:

field

May be any field in the new root segment.

For example, to invert the EMPFULL file so that the office segment is the new root, specify the field OFFICE_CODE:

```
TABLE FILE EMPFULL.OFFICE_CODE
```

You can also display a diagram of the inverted file with the CHECK FILE command (include the RETRIEVE option for a subtree diagram):

```
CHECK FILE filename.fieldname PICTURE [RETRIEVE]
```

You cannot invert a Master File if:

- The path linking the old and new roots passes through segments that have a CALC- or index-based relationship.
- The GETOWN parameter in the ACCESS File for a set-based relationship is set to N.
- It is an LRF Master File.

File inversion is a simple solution to two common problems:

- Denied access because the segment is on the wrong sort path.
- Denied access because the field named in an IF test is not on the root path.

Example: Using File Inversion to Solve Sort Path Problems

In addition to solving the sort path problem, file inversion can improve I/O efficiency which, in turn, minimizes production costs.

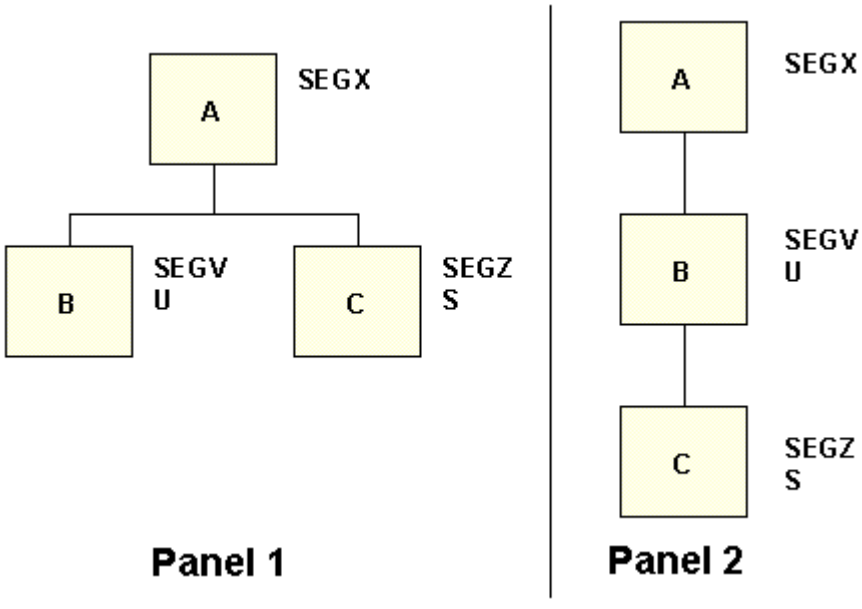
Consider this request:

```
TABLE FILE EMPFULL
LIST SKILL_LEVEL BY SALARY_GRADE
END
```

In panel 1 of the following figure, an error occurs because segments C and B are not on the same path. Therefore, you must use an inverted view:

```
TABLE FILE EMPFULL.SALARY_GRADE
LIST SKILL_LEVEL BY SALARY_GRADE
END
```

In the inverted view (panel 2), segment C is a descendant of segment B. Using this inverted view, the request can be executed.



As this request is executed, record occurrences multiply. Every record of segment C is paired with every record in segment B. If, for example, A had two B descendants and four C descendants, the report would contain eight lines of output. This effect is advantageous when it is necessary to pair every record associated with one linkpath to a record associated with another linkpath. Record pairing may produce undesirable results when the inverted segments are not directly related to each other.

If you use file inversion in conjunction with MISSING=ON, you may access orphan record occurrences that could not be accessed with the default Master File. An orphan record occurrence is one that has no parent record connection. Due to the network structure of IDMS/DB, any hierarchical view may contain orphans. IDMS/DB set connection options OA, OM, or MM indicate the possibility of orphans. Inversion enables the adapter to reconstruct the IDMS/DB relationships, so that these orphans can be retrieved.

Joining Master Files

Using WebFOCUS, you can join the Master Files describing any of these data sources to that of your IDMS/DB data source:

- Other IDMS/DB data sources (SUFFIX=IDMSR)

- VSAM or ISAM or QSAM
- SQL or UDB (Db2)
- DOS/DL1 or IMS
- CA-Datacom/DB
- MODEL 204
- Fixed-format sequential

A JOIN structure is implemented by matching one field that is common to both data sources. The fields on the IDMS/DB target file can be:

- An IDMS/DB CALC field on a network record-type.
- An indexed field (FIELDTYPE=I) on a network record-type.
- A field on an LRF record.

The fields on the host file can be:

- A virtual field located in a host Master File or created as a separate command.
- Any field.

In the Master File, the names of common fields can differ, but their field formats (ACTUAL and USAGE) must be the same.

Syntax: How to Join Two Data Sources

```
JOIN field1 [WITH rfield] IN hostfile [TAG tag1]
TO [ALL] field2 IN crfile [TAG tag2] [AS name]
[END]
```

where:

field1, field2

Are the fields common to both Master Files.

WITH *rfield*

Use only if *field1* is a virtual field; assigns a logical home with a real field in the host file.

hostfile

Is the host Master File.

`TAG tag1`

Is a tag name of up to eight characters (usually the name of the Master File), which is used as a unique qualifier for fields and aliases in the host file.

The tag name for the host file must be the same in all the JOIN commands of a joined structure.

`ALL`

Use if non-unique relationships exist in the target file.

`crfile`

Is the target or cross-referenced Master File.

`TAG tag2`

Is a tag name of up to eight characters (usually the name of the Master File), which is used as a unique qualifier for fields and aliases in the cross-referenced file. In a recursive joined structure, if no tag name is provided, all field names and aliases are prefixed with the first four characters of the join name.

`AS name`

Assigns a name to the JOIN structure. You must assign a unique name to a join structure if:

- You want to ensure that a subsequent JOIN command will not overwrite it.
- You want to clear it selectively later.
- The structure is recursive, and you do not specify tag names.

`END`

Required when the JOIN command is longer than one line; terminates the command.

To join more than two files as a single structure, indicate the common fields as follows:

```
JOIN field1 IN file1 TO field2 IN file2 AS name1
JOIN field3 IN file1 TO field4 IN file3 AS name2
```

Reference: Usage Notes for the JOIN Command

- Up to 16 joins may be active in one session.
- For a DML target file, field2 must be indexed (FIELDTYPE=I).

- If you intend to use a virtual field as *field1*, specify its field name in the JOIN command and then issue its DEFINE command. Any DEFINE commands issued prior to the JOIN are cleared.
- If you know that the target file is unique, omit the ALL in the JOIN command; omitting ALL reduces I/O overhead.
- To display the JOIN structure, use the CHECK FILE command and specify the name of the host file.

Syntax: How to List JOIN Structures

To list your JOIN structures, enter:

```
? JOIN
```

Syntax: How to Clear JOIN Structures

To clear a specific JOIN structure, specify the name that you assigned to the join:

```
JOIN CLEAR name
```

Syntax: How to Clear All JOIN Structures

To clear all structures, use an asterisk (*) instead of a join name:

```
JOIN CLEAR *
```

Example: Reporting From a Joined Structure

This example joins the DML data source JOBFILE to the IDMS/DB EMPFULL data source based on job codes. First the JOBCODE field in JOBFILE is edited to make it compatible with the JOB_ID field in EMPFULL. The JOIN command is issued prior to the DEFINE. If the DEFINE were issued first, it would be cleared by the JOIN command:

```
JOIN JOBID WITH JOBCODE IN JOBFILE TO
ALL JOB_ID IN EMPFULL AS J1
END
DEFINE FILE JOBFILE
JCODE/A2 = IF JOBCODE LIKE 'A__' THEN '10' ELSE '20';
JOBID/A4 = JCODE|EDIT(JOBCODE,'$99');
END
TABLE FILE JOBFILE
SUM EMP_NAME IN 25 TITLE
BY DEPT_NAME
END
```

The output is:

```
DEPT_NAME               EMP_NAME                    TITLE
---------               --------                    -----
ACCOUNTING AND PAYROLL  RUPERT    JENSON            MGR ACCTNG/PAYROLL
PERSONNEL               ELEANOR   PEOPLES           MGR PERSONNEL
```

Tracing the Adapter for IDMS/DB

From the Web Console main screen, select *Diagnostics* and click *Enable Traces*. The default traces include the Adapter for IDMS/DB trace information.

Chapter 37

Using the Adapter for CA-IDMS/SQL

The Adapter for CA- IDMS/SQL allows applications to access IDMS/SQL data sources. The adapter converts application requests into native IDMS/SQL statements and returns optimized answer sets to the requesting application.

In order to use the Adapter for CA-IDMS/SQL, you must configure and map data to its corresponding server counterparts. Check with your Server Administrator for further information.

Note: For the remainder of this manual, the name IDMS/SQL refers to CA-IDMS/SQL.

In this chapter:

Preparing the IDMS/SQL Environment

Prior to configuring the Adapter for IDMS/SQL using the Web Console, it is necessary to edit the ISTART JCL used to initiate the server. The changes required are documented as follows:

- Allocate the IDMS.LOADLIB and IDMS.DBA.LOADLIB libraries to the server's STEPLIB ddname allocation.
- Allocate ddname SYSCTL to the IDMS.SYSCTL data set.
- Allocate ddname SYSIDMS to the IDMS.SYSIDMS data set.

Configuring the Adapter for IDMS/SQL

Configure the adapter using the Web Console Adapter Add screen and click *Configure*.

In order to connect to an IDMS/SQL database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one IDMS/SQL database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to IDMS/SQL Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Overriding the Default Connection

An SQL session is a connection between the application and the IDMS/SQL data source. It begins when the application connects to a dictionary. You use the CONNECT command to override the IDMS/SQL default (automatic) connection. The length of time an SQL session stays in effect depends on whether the connection began automatically or a CONNECT command was issued. If the CONNECT command was issued, the SQL session is in effect until a COMMIT RELEASE, ROLLBACK RELEASE, or RELEASE command is executed. All of these commands may be executed within the IDMS/SQL session using SQL Passthru. Refer to the appropriate IDMS documentation for more information regarding SQL sessions.

Syntax: How to Override Default Connections With the CONNECT Command

Issue the following syntax within a stored procedure

```
ENGINE SQLIDMS CONNECT TO dictionary
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`dictionary`

Is the data source (dictionary) to start the IDMS/SQL session. The default is the dictionary in effect for the user session. This default is set outside of the server session, for example, with a SYSIDMS DICTNAME parameter. Refer to the appropriate IDMS documentation for a complete description.

Other Session Commands

Other IDMS/SQL commands that affect the IDMS/SQL session can be executed explicitly.

To issue IDMS/SQL session commands such as COMMIT, COMMIT RELEASE, ROLLBACK, ROLLBACK RELEASE, and COMMIT CONTINUE, the syntax is:

```
ENGINE SQLIDMS COMMIT RELEASE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLIDMS SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

The COMMIT setting frees the thread of execution for use by other users. The disadvantage is the cost of repeatedly connecting and acquiring a thread. Threads, once released, may not be available when needed, so you may experience delays while your request waits for a thread.

Depending on how often the event occurs, the AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server; it is related to the operating system and the data source.

Managing IDMS/SQL Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the IDMS/SQL data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each IDMS/SQL table or view that is accessible from the server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for IDMS/SQL

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *IDMS/SQL Data Type Support* on page 992.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for IDMS/SQL synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLIDMS ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4,    I9,  I4,  MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON  ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9,  I4,  MISSING=ON  ,$
```

Generated Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=IDMS901,KEYS=1, WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Name of the table or view. This value can include a location or owner name as follows: TABLENAME=[*location.*][*owner.*]*tablename*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local database server. Absence of the CONNECTION attribute indicates access to the default database server.
DBSPACE	Optional keyword that indicates the storage area for the table. For example: *datasource.tablespace* DATABASE *datasource*
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.

Keyword	Description
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❏ KEYFLD is the FIELDNAME of the common column from the parent table. ❏ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.
INDEX_NAME INDEX_UNIQUE INDEX_COLUMNS INDEX_ORDER	Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Master Files

The following describes the three types of Master File declarations:

Declaration Type	Description
File	Names the file and describes the type of data source.

Declaration Type	Description
Segment	Identifies a table, file, view, or segment.
Field	Describes the columns of the table or view.

Each declaration must begin on a separate line. A declaration consists of attribute-value pairs separated by commas. A declaration can span as many lines as necessary, as long as no single keyword-value pair spans two lines.

Do not use system or reserved words as names for files, segments, fields, or aliases. Specifying a reserved word generates syntax errors.

Syntax: How to Declare File Attributes

Each Master File begins with a file declaration. The file declaration has two attributes, FILENAME and SUFFIX:

```
FILE[NAME]=file, SUFFIX=SQLIDMS [,$]
```

where:

file

Identifies the Master File. The file name can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents.

SQLIDMS

Is the value for the adapter.

Syntax: How to Declare Segment Attributes

Each table described in a Master File requires a segment declaration. The segment declaration consists of at least two attributes, SEGNAME and SEGTYPE:

```
SEGNAME=segname, SEGTYPE=S0 [,$]
```

where:

segname

Is the segment name that serves as a link to the actual IDMS/SQL table name. It can consist of a maximum of 8 alphanumeric characters. It may be the same as the name chosen for FILENAME, the actual table name, or an arbitrary name.

The SEGNAME value in the Master File must be identical to the SEGNAME value specified in the Access File.

S0

Indicates that IDMS/SQL assumes responsibility for both physical storage of rows and the uniqueness of column values (if a unique index or calc key exists). It always has a value of S0 (S zero).

Syntax: How to Declare Field Attributes

Each row in a table may consist of one or more columns. These columns are described in the Master File as fields with the primary field attributes, FIELDNAME, ALIAS, USAGE, ACTUAL, MISSING.

Note: You can get values for these attributes from the IDMS/SQL schema definition or standard IDMS/SQL dictionary reports.

```
FIELD[NAME]=fieldname, [ALIAS=]sqlcolumn, [USAGE=]display_format,
[ACTUAL=]storage_format [,MISSING={ON|OFF}], $
```

where:

fieldname

Is the unqualified name of the field. This value must be unique within the Master File. The name can consist of a maximum of 48 alphanumeric characters (including any file name and segment name qualifiers and qualification characters you may later prefix to them in your requests). The name must begin with a letter. Special characters and embedded blanks are not recommended. The order of field declarations in the Master File is significant with regard to the specification of key columns. For more information, see *Primary Key* on page 992.

It is not necessary to describe all the columns of the IDMS/SQL table in your Master File.

sqlcolumn

Is the full IDMS/SQL column name (the adapter uses it to generate SQL statements). This value must comply with the same naming conventions described for field names.

display_format

Is the display format. The value must include the field type and length and may contain edit options.

The data type of the display format must be identical to that of the ACTUAL format. For example, a field with an alphanumeric USAGE data type must have an alphanumeric ACTUAL data type.

Fields or columns with decimal or floating-point data types must be described with the correct scale (s) and precision (p). Scale is the number of positions to the right of the decimal point. Precision is the total length of the field.

For the server, the total display length of the field or column includes the decimal point and negative sign. In SQL, the total length of the field or column excludes positions for the decimal point and negative sign.

For example, a column defined as DECIMAL(5,2) would have a USAGE attribute of P7.2 to allow for the decimal point and a possible negative sign.

storage_format

Is the storage format of the IDMS/SQL data type and length, in bytes, for the field.

ON

Displays the character specified by the NODATA parameter for missing data. For more information, see *MISSING Attribute* on page 990.

OFF

Displays blanks or zeroes for fields having no value. OFF is the default value. For more information, see *MISSING Attribute* on page 990.

MISSING Attribute

In a table, a null value represents a missing or unknown value. It is not the same as a blank or a zero. For example, a column specification that allows null values is used where a column need not have a value in every row (such as a raise amount in a table containing payroll data).

Note:

- The default NODATA character is a period (.).
- A column in an IDMS/SQL table that allows null data does not need to include the NULL clause in its table definition, since that is the default. In the Master File for that table, the column that allows null data must be described with the MISSING attribute value ON. The default for this attribute is OFF, which corresponds to the NOT NULL attribute in the IDMS/SQL table definition.
- Null data values appear as zeroes or blanks, if the column allows null data but the corresponding field in the Master File is described with the MISSING attribute value OFF.

Access Files

Each Master File must have a corresponding Access File. The file name of the Access File must be the same as that used for the Master File.

The Access File serves as a link between the server and the data source by providing the means to associate a segment in the Master File with the table it describes. The Access File minimally identifies the table and primary key. It may also indicate the logical sort order of data.

Syntax: How to Establish Segment Declarations

The segment declaration in the Access File establishes the link between one segment of the Master File and the actual IDMS/SQL table or view. Attributes that constitute the segment declaration are:

```
SEGNAME=segname, TABLENAME=[schema.]tablename, [,DBSPACE=storage,]
  [,KEYS={0|n}] [,KEYORDER={ASC|LOW|HIGH|DESC}]  ,$
```

where:

segname

Is the 1- to 8-character SEGNAME value from the Master File.

schema

Is the IDMS/SQL schema name for the table or view. It can consist of a maximum of 8 characters. If it is not specified, IDMS/SQL searches for a temporary table definition for the named table. If the named table does not exist, IDMS/SQL uses the current schema in effect for the current user session.

tablename

Is the name of the table or view. It can consist of a maximum of 18 characters.

Note: If any part of the TABLENAME includes a dollar sign ($), enclose that part in double quotation marks, and enclose the entire TABLENAME value in single quotation marks.

The maximum IDMS/SQL length for a fully qualified tablename is 36. All names must conform to the rules for identifiers stated in the *CA-IDMS/DB Release SQL Reference* manual.

storage

Is the IDMS/SQL segment and area name (in the form segment.area). If not specified, IDMS/SQL uses the default area associated with the schema. Enclose it in double quotation marks if it begins with a number or special character or contains special characters.

The Access File DBSPACE attribute overrides both the SET command and the installation default.

n

Is the number of columns that constitute the primary key. It can be a value between 0 and 64. 0 is the default value. For more information, see *Primary Key* on page 992.

LOW (ASC)

Indicates an ascending primary key sort sequence. LOW is the default value. ASC is a synonym for LOW.

HIGH (DESC)

Indicates a descending primary key sort sequence. DESC is a synonym for HIGH.

Primary Key

The primary key of a table consists of the column or combination of columns whose values uniquely identify each row of the table. In the employee table, for example, every employee is assigned a unique employee identification number. Each employee is represented by one and only one row of the table, and is uniquely identified by that identification number.

The order of field declarations in the Master File is significant to the specification of key columns. To define the primary key in a Master File, describe its component fields immediately after the segment declaration. You can specify the remaining fields in any order. In the Access File, the KEYS attribute completes the process of defining the primary key.

To identify the primary key, the adapter uses the number of columns (n) indicated by the KEYS attribute in the Access File and the first n fields described in the Master File.

Typically, the primary key is supported by the creation of a unique index in the SQL language to prevent the insertion of duplicate key values. The adapter itself does not require any index in the column(s) comprising the primary key (although a unique index is certainly desirable for both data integrity and performance reasons).

IDMS/SQL Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96

Customizing the IDMS/SQL Environment

The Adapter for IDMS/SQL provides several parameters for customizing the environment and optimizing performance. This topic provides an overview of customization options.

Setting the User-specific Schema Name

The Adapter for IDMS/SQL uses the user-specified schema name as the first qualifier for all SQL requests involving SQL tables or views. This command overrides the IDMS/SQL current schema in effect and precludes the specification of unqualified table names. This prevents passing of unqualified table names to IDMS/SQL.

Syntax: How to Set SESSION

```
ENGINE SQLIDMS SET SESSION CURRENT SCHEMA schema
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`schema`

Is the name of the schema in SQL requests.

Controlling Transactions

IDMS/SQL protects data being read by one user from changes (INSERT, UPDATE, or DELETE) made by others. The Isolation Level setting governs the duration of the protection. That is, the Isolation Level determines when shared locks on rows are released, so that those rows or pages become available for updates by other users. IDMS/SQL allows you to dynamically set the Isolation Level within the server session using the IDMS/SQL SET TRANSACTION command.

The SET TRANSACTION CURSOR STABILITY or TRANSIENT READ command affects the duration of row or page shared locks on IDMS/SQL tables for the duration of the IDMS/SQL transaction. You can specify the command within a stored procedure. The setting remains in effect for the server session or until you reset it.

Syntax: How to Control Transactions

```
ENGINE SQLIDMS SET TRANSACTION
 {CURSOR STABILITY|TRANSIENT READ|READ ONLY|READ WRITE}
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`CURSOR STABILITY`

Provides the maximum amount of concurrency while guaranteeing the integrity of the data selected. CURSOR STABILITY is the default value.

`TRANSIENT READ`

Allows the reading of records locked by other users. This is recommended for SQL request only. Transient read prevents the SQL transaction from performing updates. Use this only when you do not need the data retrieved to be absolutely consistent and accurate. If you specify Transient Read, IDMS/SQL assumes it is read-only.

`READ ONLY`

Allows data to be retrieved, but does not allow the data source to be updated.

`READ WRITE`

Allows data to be retrieved, and allows the data source to be updated.

Designating a Default Tablespace

You can use the SET DBSPACE command to designate a default tablespace for tables you create.

For the duration of the session, the adapter places these tables in the IDMS/SQL tablespace that you identify with the SET DBSPACE command. If the SET DBSPACE command is not used, IDMS/SQL uses the default tablespace for the connected user.

Syntax: How to Set DBSPACE

```
ENGINE SQLIDMS SET DBSPACE storage
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`storage`

Is the segment.area name that will contain the IDMS/SQL tables created by the CREATE FILE command. If a name is not specified, the table will be placed in the IDMS/SQL default area for the current schema in effect for the user's SQL session.

Note: This command will only affect CREATE TABLE requests made by Table Services. It does not affect Passthru CREATE TABLE commands.

Overriding Default Parameters for Index Space

You can use the SET IXSPACE command to override the default parameters for the IDMS/SQL index space implicitly created by the CREATE FILE and HOLD FORMAT SQLIDMS commands.

Syntax: How to Set IXSPACE

```
ENGINE SQLIDMS SET IXSPACE [index-spec]
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`index-spec`

Is the portion (up to 94 bytes) of the SQL CREATE INDEX statement beginning with IN segment.area (as specified in the *CA-IDMS/DB Reference* CREATE INDEX syntax diagram).

Note: To reset to the IDMS/SQL default index space parameters, issue the SET IXSPACE command with no operands.

Example: Specifying Segment.Area Name and Index Block

The following example shows how to set the segment.area name and INDEX BLOCK of the CREATE INDEX statement with IXSPACE:

```
ENGINE SQLIDMS
SET IXSPACE IN EMPSEG.EMPAREA INDEX BLOCK CONTAINS 5 KEYS
END
```

You can use the SQL ? query command to determine the current IXSPACE setting. If the current setting is the default, IXSPACE does not display in the SQL SQLIDMS ? output.

Note: This command will only affect CREATE INDEX requests made by Table Services. It does not affect Passthru CREATE INDEX commands.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLIDMS SET PASSRECS {ON|OFF}
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides an informational message after the successful execution of an SQL Passthru UPDATE or DELETE command. ON is the default value.

`OFF`

Does not provide a message after the successful execution of an SQL Passthru UPDATE or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.

Note that since, by definition, the successful execution of an INSERT command always affects one record, INSERT does not generate this information.

IDMS/SQL Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Specifying Block Size for Retrieval Processing

The Adapter for IDMS/SQL supports array retrieval from result sets produced by executing SELECT queries or stored procedures. This technique substantially reduces network traffic and CPU utilization.

Using high values increases the efficiency of requests involving many rows, at the cost of higher virtual storage requirements. A value higher than 100 is not recommended because the increased efficiency it would provide is generally negligible.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

Syntax: How to Specify the Block Size for Array Retrieval

The block size for a SELECT request applies to TABLE FILE requests, MODIFY requests, MATCH requests, and DIRECT SQL SELECT statements.

```
ENGINE SQLIDMS SET FETCHSIZE n
```

where:

`SQLIDMS`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is the number of rows to be retrieved at once using array retrieval techniques. Accepted values are 1 to 5000. The default varies by adapter. If the result set contains a column that has to be processed as a CLOB or a BLOB, the FETCHSIZE value used for that result set is 1.

Chapter 38

Using the Adapter for IMS

The Adapter for IMS allows applications to access IMS data sources. The adapter converts application requests into native IMS statements and returns optimized answer sets to the requesting application.

The Adapter for IMS is supported on the z/OS platform and uses the IMS DBCTL environment to connect to IMS databases.

In this chapter:

IMS Environments: Overview

The Adapter for IMS supports the DBCTL environment to connect to IMS databases.

Advantages of IMS DBCTL

The advantages of using DBCTL include the following:

- **Direct communication between your application and IMS.** Your task establishes its own connection to IMS by loading and calling the DBCTL subsystem when needed. It then issues DL/I calls directly to IMS.
- **Enhanced security.** You have access to standard security systems through the standard SAF interface. The SAF interface is supported by security products such as RACF, CA-TOP SECRET, and CA-ACF2. Before allowing access to a particular PSB, the system verifies that the user is authorized to read the PSB.

- **Dynamic PSB selection and switching within your application.** When you have Access Files, you do not have to issue a command to select a PSB, so the selection is transparent to your application.
- **Sharing of PCBs between applications.** Multiple users can share the same PCBs, reducing the number of duplicate PCBs in a PSB and minimizing overhead.
- **IMS SET ? query command.** DBCTL enables you to view current settings (PSB, IMSSEC, IMSCLASS, IMSMODE, IMSPZP) by issuing the IMS SET ? query command.
- **Read/write capabilities.**
- **Creation of Master and Access files using the Web Console.**

Preparing the IMS Environment

This section describes steps for preparing the IMS DBCTL environment.

Before configuring the Adapter for IMS verify that your site is running an IBM-supported version of IMS and that all APPLCTN macros describing PSBs that will be accessed by multiple users specify SCHDTYP=Parallel. If necessary, modify the APPLCTN macros for such PSBs to include the attribute SCHDTYP=Parallel, and rerun the IMS SYSGEN to make the changes effective.

The Adapter for IMS connects using the DBCTL environment. For the connection to be made, the following libraries must be identified and allocated to the STEPLIB in the IRUNJCL JCL member of your server configuration file:

- The DFSPZP library.
- The SDFSRESL library.

Note: For example, for PDS deployment, the server configuration file is of the form *qualif*.*release*.*server_type*.DATA where *qualif* is provided by the user. The *release* and *server_type* vary with the release and license key being used. Refer to the Server Installation for z/OS in the *Server Installation* manual for further information on the configuration data set naming convention.

The PZP library must have a member that has been generated to identify the correct DBCTL environment for the connection. The following steps must be completed before the server can be configured, using the Web Console or Data Management Console, for the Adapter for IMS:

1. *How to Create the DRA Startup Table: DFSPZPxx*
2. *Assembling and Linking the DRA Startup Table*
3. *Establishing Security*

Syntax: How to Create the DRA Startup Table: DFSPZPxx

The Database Resource Adapter (DRA) is the interface between a user task and DBCTL. The DRA Startup Table contains values that define the characteristics of the DRA. The name of the DRA Startup Table is

```
DFSPZPxx
```

where:

xx

Is a two-character suffix that should be chosen to comply with your site standards.

Once this suffix has been chosen, its value is needed during the configuration phase using the Web Console or Data Management Console.

Example: Assembling and Linking the DRA Startup Table

This sample JCL illustrates how to assemble and link the DFSPZPxx member. You can normally find sample JCL in your IMS installation library.

```
//job card goes here
//ASSEMBLE EXEC  PGM=ASMA90,REGION=2M,PARM='OBJECT,NODECK'
//SYSLIB     DD DSN=IMS.MACLIB,DISP=SHR
//SYSLIN     DD UNIT=SYSDA,DISP=(,PASS),
//               SPACE=(80,(100,100),RLSE),
//               DCB=(BLKSIZE=80,RECFM=F,LRECL=80)
//SYSPRINT   DD SYSOUT=*,DCB=BLKSIZE=1089
//SYSUT1     DD UNIT=SYSDA,DISP=(,DELETE),
//               SPACE=(CYL,(10,5))
//SYSIN      DD    *
PRP      TITLE 'DATABASE RESOURCE ADAPTER STARTUP PARAMETER TABLE'
DFSPZPxx CSECT
         EJECT
         DFSPRP DSECT=NO,                                              X
               DBCTLID=IMSx,                                           X
               DDNAME=DFSRESLB,                                        X
               DSNAME=IMS.RESLIB,                                      X
               CNBA=150,                                               X
               MAXTHRD=150,                                            X
               MINTHRD=5
         END
/*
//*
//LINK     EXEC  PGM=IEWL,PARM='XREF,LIST',COND=(0,LT,ASSEMBLE),
//                 REGION=4M
//SYSLIN     DD DSN=*.ASSEMBLE.SYSLIN,DISP=(OLD,DELETE)
//SYSPRINT   DD SYSOUT=*,DCB=BLKSIZE=1089
//SYSUT1     DD UNIT=(SYSDA,SEP=(SYSLMOD,SYSLIN)),
//               SPACE=(1024,(100,10),RLSE),DISP=(,DELETE)
//SYSLMOD    DD DISP=SHR,DSN=qualif.outputlib
```

where:

x

Is the IMS version number.

qualif.outputlib

Is the output library where the PZP module (DRA Startup Table) will be stored.

xx

Is the two-character suffix chosen for the DRA Startup Table.

Note: The *qualif.outputlib* library must be concatenated ahead of IMS.RESLIB in the allocation for DDNAME STEPLIB in the IRUNJCL member of your server configuration file.

Reference: **Keywords for Generating the DFSPZP Library**

The following chart describes the keywords required to generate the DFSPZP library. Other keywords that affect your IMS environment, and may be required at your site, are described in the *IBM IMS System Definition Reference*.

Keyword	Description	Default
AGN	Is a 1 to 8 character application group name used as part of the DBCTL security function. For more information on DBCTL security, see the *IMS System Administration Guide*.	N/A
CNBA	Is the total number of Fast Path buffers for the server. For a description of Fast Path DEDB buffer usage, see the *IMS System Administration Guide*. You can omit this parameter if your site does not utilize Fast Path.	N/A
DBCTLID	Is the 4-character name of the DBCTL region. This is the same as the IMSID parameter in the DBC procedure. For more information on the DBC procedure, see the *IBM IMS System Definition Reference*.	SYS1

Keyword	Description	Default
DDNAME	Must be DFSRESLB. It is the DDNAME that will be allocated to the DBCTL RESLIB library (see the DSNAME keyword).	N/A
DSNAME	Is the 1- to 44-character data set name of the DBCTL RESLIB library. It must contain the DRA modules and be MVS authorized.	IMS.RESLIB
FPBOF	Is the number of Fast Path DEDB overflow buffers to be allocated per thread. For a description of Fast Path DEDB buffer usage, see the *IMS System Administration Guide*. You can omit this keyword if your site does not use Fast Path.	00
FPBUF	Is the number of Fast Path DEDB buffers to be allocated and fixed per thread. For a description of Fast Path DEDB buffer usage, see the *IMS System Administration Guide*. You can omit this parameter if your site does not utilize Fast Path.	00
FUNCLV	Is the level of the DRA that the CCTL supports. FUNCLV=1 means the CCTL uses the DRA at the IMS 3.1 level.	1
MAXTHRD	Is the maximum number of concurrent DRA threads. The value cannot exceed 255.	1
MINTHRD	Is the minimum number of concurrent DRA threads available. Since the number of threads specified by this keyword will be allocated at all times, regardless of whether they are used, be careful when selecting this value. The value cannot exceed 255.	1
SOD	Is the output class to use for a SNAP DUMP of abnormal thread termination.	A

Keyword	Description	Default
TIMEOUT	Is the number of seconds a CCTL should wait for the successful completion of a DRA TERM request. Specify this value only if the CCTL is coded to use it. This value is returned to the CCTL upon completion of an INIT request.	60
TIMER	Is the number of seconds between attempts of the DRA to identify itself to DBCTL during an INIT request.	60
USERID	Is the 8-character name of the CCTL region. No two CCTLs (servers accessing the same IMS region through DBCTL) can have the same USERID (address space ID).	N/A

Establishing Security

The DBCTL environment, when accessed through the server, enables the use of security systems through the standard SAF interface. With the SAF interface, your site can use security products such as RACF, CA TOP SECRET, and CA ACF2 to restrict access to PSBs. Before allowing access to a particular PSB, the security system verifies that the user is authorized to read the PSB.

Note: The DBCTL function is tested and verified with the RACF product. Other SAF products using identical calls should perform properly when installed and verified by your site's security administrator.

RACF comes with several predefined security classes. Customer sites can use an existing class (such as PCICSPSB) or define a resource class specifically for DBCTL use.

Syntax: How to Define a PSB Resource

The following syntax illustrates how to define a PSB resource through a PCICSPSB profile to RACF, and how to grant users permission to access the resource.

```
RDEFINE PCICSPSB (psbname) UACC(NONE) NOTIFY(sys_admin_userid)
PERMIT psbname CLASS(PCICSPSB) ID(user_or_group [user_or_group ...])
ACCESS(READ)
```

where:

psbname

Is a PSB name to be protected by RACF.

sys_admin_userid

Is the user ID of the system administrator.

user_or_group

Authorizes the user IDs and/or user groups listed in the PERMIT command to read the specified PSB. Separate items in the list with blanks.

At run time, after the PSB is selected, but prior to scheduling it, the server issues a call to the security system and verifies that the user is authorized to read the PSB.

Configuring the Adapter for IMS

This section describes configuration steps and parameters for the Adapter for IMS in the DBCTL environment.

Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note: Restart the server so the connection to DBCTL can be initialized.

Reference: Connection Attributes for IMS DBCTL

The IMS Adapter in under the *DBMS* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

IMS Sec

ON activates DBCTL security. This setting requires that the server be in authorized mode.

OFF does not implement DBCTL security.

IMS DBCTL

START.

IMS RECONNECT

The adapter uses the IMS DBCTL environment to connect to IMS databases. Reconnection to DBCTL is now handled automatically using the IMS RECONNECT parameter.

The default reconnection time interval is 2 minutes. However, if an ABEND occurs during an IMS shut down, you must increase the reconnection time interval.

Note: For best results, we strongly recommend that you use the IMS /CHECKPOINT FREEZE command as your mechanism for shutting IMS down.

If this parameter is set to 0, reconnection works as in previous releases, without automatic restart. In this case, you must restart the server to establish the connection to DBCTL.

IMS Class

Points to a valid class that contains the security rule. The Systems Administrator can define any class name required by the security implementation of the site. The default value is PCICSPSB.

IMS PZP

The suffix of the IBM/IMS DFSPZP module that is created during the IMS/DBCTL installation process. For more information, see in *How to Create the DRA Startup Table: DFSPZPxx* on page 1001.

Managing IMS Metadata

When the server accesses a data source, it needs information on how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the IMS data types.

You can create metadata entirely from the Web Console or the Data Management Console. The generated synonyms consist of a Master File and an Access File.

Creating Synonyms

Synonyms define unique names (or aliases) for each IMS PSB that is accessible from a server. Synonyms are useful because they hide location information and the identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

For the Adapter for IMS to access an IMS PSB, you must create a synonym for each IMS PSB you access. The logical description of an IMS file is stored in a Master File, which describes the field layout.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for IMS

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Filter PSB Name

Selecting this check box adds a Name input field that allows you to filter the PSB names for which you wish to create synonyms.

Enter a string for filtering the PSB names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter ABC% to select PSBs which begin with the letters ABC; %ABC to select PSBs which end with the letters ABC; %ABC% to select PSBs which contain the letters ABC at the beginning, middle, or end

DBD library name

Is the MVS library name that corresponds to the IMS DBDLIB. This must be a fully qualified MVS data set name.

PSB library name

Is the MVS library name that corresponds to the IMS PSBLIB. This must be a fully qualified MVS data set name.

PSB Selection

Select a member name from the drop-down list.

COBOL FD Selection Options

Map using COBOL FDs

Select this option if you have a Cobol FD library available that describes the PCB view. You have to select segments in this case.

If you do not select this option, the final screen opens without the option to select a Cobol FD entry. Create Synonym then creates a skeleton synonym using the Data Base Definition defined fields.

File System

Select one of the following from the drop-down list:

- *Fully qualified PDS name* to enter a fully qualified MVS Library in the entry box.
- *Absolute HFS directory pathname* to enter the HFS location that contains the COBOL FD.
- *Applications* to enter a pre-configured HFS directory.

PDS name or Directory name

Depending on your selection for File System, enter the fully qualified PDS name or absolute directory path that contains the COBOL FD.

Member Name or File Name

Depending on your selection for File System, enter the member name or file that contains the COBOL FD.

You can enter a string for filtering these names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter ABC% to select names which begin with the letters ABC; %ABC to select names which end with the letters ABC; %ABC% to select names which contain the letters ABC at the beginning, middle, or end.

File Extension

If you selected *Absolute HFS directory pathname* as the file system, enter the extension of the file that contains the COBOL FD.

COBOL FD

For each segment that you want to map using a COBOL FD, select the appropriate COBOL FD from the drop-down list.

Additional Options

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Example: Creating a Synonym

Use the following steps to create a synonym for the AIHDAM data source:

1. From the Web Console menu bar, click *Applications.*

   The Applications page opens.

2. Click the *New* button and select *Synonym* from the drop-down menu.

   The *Select adapter to configure* or *Select connection to create synonym* pane opens.

3. Click *IMS DBCTL*.

   Note: You can also create a synonym from the Adapters page by right-clicking the configured IMS connection and selecting *Create Synonym*.

4. Enter the fully qualified DBD library name in the DBD Library input box. For example:

   ```
   IMS.V7R1M0.B.DBDLIB
   ```

5. Enter the fully qualified PSB library name in the PSB Library input box. For example:

   ```
   IMS.V7R1M0.B.PSBLIB
   ```

6. Check Filter PSB Name and enter the following mask in the text box that displays:

   ```
   ai%
   ```

7. Click *Next*.

   The PSB Selection screen opens.

8. Select the appropriate PSB name from the drop-down list, for example: AIHDPSB.
9. If you have a COBOL FD for the database, check *Map using COBOL FDs*.
10. Click *Next*.

    The PCB Selection screen opens.

11. Select the appropriate PCB, for example, PCB number 5 (which has a secondary index defined).
12. Optionally, edit the name for the synonym in the Default Synonym Name column and select the application under which you want to create this synonym (the default application is baseapp).

13. If you checked *Map using COBOL FDs* in Step 9, enter the information about the COBOL FD for the file system you use for each segment:

    - If you select *Fully qualified PDS name*, enter the name of the PDS that contains the COBOL FD and the member name of the COBOL FD.
    - If you select *Absolute HFS directory pathname* enter the path to the COBOL FD and its file name and extension.
    - If you select *Applications*, choose from the provided HFS directories.

14. Click *Create Synonym*.

    You should get a message indicating that the synonym was created successfully.

15. To view the Master File created, go to the Metadata page, open the application under which you created the synonym, click the synonym name, and select *Edit as Text* from the context menu. This example resulted in the following Master File:

```
FILENAME=AIHDAM, SUFFIX=IMS     , $
  SEGMENT=LANGUAGE, SEGTYPE=S0, $
$  GROUP=AIHDAM_IO, ALIAS=E1, USAGE=A19, ACTUAL=A19, $
    FIELDNAME=EMPL6, ALIAS=EMPL6.HKY, USAGE=I11, ACTUAL=I4, $
    FIELDNAME=LANG6, ALIAS=LANG6.IMS, USAGE=A15, ACTUAL=A15, $
```

16. To view the Access File created, go to the Metadata page, open the application under which you created the synonym, click the synonym name, and select *Edit Access File as Text* from the context menu. This example resulted in the following Master File:

```
PSB=AIHDPSB, WRITE=NO, PCBNUMBER=5, PL1=NO, $
  SEGNAME=LANGUAGE, KEYTYPE=S0, $
      XDFLD=IXEMP6, SRCH=EMPL6, ALTPCBNUMBER=5, $
```

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Defining Subsets of DBD Segments and IMS Fields in Segments

The SENSEG parameter is used in a PCB description to define a subset of accessible DBD segments. CREATE SYNONYM produces Master File segments based on the SENSEG information obtained from the PSB, and not from the database definition.

The SENSFLD parameter is used in a PCB description to define a subset of accessible IMS fields in a segment. IMS fields are defined in the DBD. The list of fields in a Master File SEGMENT is generated based on the SENSFLD information, and not on the DBD field definitions.

SENSFLD macros can redefine the layout of an IMS database segment record by using the "START = xx" parameter. Different layouts can be defined in the DBD and SENSFLD. The Master File segment layout (field information) is derived from the SENSFLD.

Master File Attributes

Each Master File that provides access to an IMS data source describes the segments and fields that are available through one IMS PCB.

Note: You do not have to describe every segment from the PCB in the Master File. However, the portion of the hierarchy you describe must be a subtree starting from the root. Any segment or field that you do not describe in the Master File remains invisible to the server.

Reporting costs are largely a function of the volume of data transferred. Therefore, requests issued through the adapter are efficient and cost effective, because only segments referenced in your request are retrieved.

In a Master File, you can define as many segments as WebFOCUS supports as long as the cumulative length of all fields across all segments does not exceed 12,000 bytes (an IMS restriction). See *How to Specify IMS Field Attributes* on page 1015 for additional information about this limit.

Each Master File is stored as a member of a Master File PDS or HFS directory. The member name for a Master File must be the name assigned to that Master File in the Access File record for the corresponding PCB. At run time, the Master File data set is allocated to ddname MASTER.

A Master File consists of file, segment, and field declarations. Rules for declarations are:

- Each declaration must begin on a separate line and be terminated by a comma and dollar sign (,$). Text appearing after the comma and dollar sign is treated as a comment.
- A declaration can span as many lines as necessary as long as no attribute=value pair is separated. Commas separate attribute=value pairs.

Syntax: How to Identify Master Files for IMS

Each Master File begins with a file declaration that names the file and describes the type of data source, an IMS data source in this case. The file declaration has two attributes, FILENAME and SUFFIX.

```
FILE[NAME]=name, SUFFIX=IMS [,$]
```

where:

name

Is any 1- to 8-character name.

IMS

Indicates that the Adapter for IMS is required for data retrieval.

Syntax: How to Specify IMS Segment Attributes

Each IMS segment described in a Master File requires a segment declaration that consists of at least two attributes, SEGNAME and SEGTYPE. The SEGNAME value is the name of the corresponding IMS segment. The SEGTYPE value identifies the segment characteristics.

```
SEGNAME=segname, SEGTYPE=segtype [,PARENT=parent] [,$]
```

where:

segname

Is the 1- to 8-character IMS segment name from the NAME parameter of the SENSEG record in the IMS PCB.

segtype

Is S0 or U. U is used to identify unique segments that are data sensitive. A unique segment has no twins (PTR=NOTWIN in the IMS DBD). While a parent segment can have many *types* of unique children, it can have at most one *instance* of each type.

Note: In older releases of the adapter, the SEGTYPE attribute was also used to identify the segment's key type. While those SEGTYPE values are still supported by the adapter, new synonyms created using the Web Console or Data Management Console identify these characteristics using the KEYTYPE attribute in the Access File. For information, see *KEYTYPE in IMS* on page 1033.

parent

Is the name of the parent segment from the IMS data source. Its value comes from the PARENT parameter of the SENSEG record in the IMS PCB.

SEGNAME in IMS

The SEGNAME attribute identifies the IMS segments you can access. The SEGNAME value is the name of the IMS segment from the SENSEG record in the PCB.

The server retrieves segments in top-to-bottom left-to-right sequence as described by the Master File. Therefore, the order of segments in the Master File should be the same as their order in the PCB to maintain the correct hierarchical sequence.

SEGTYPE in IMS

The SEGTYPE attribute is either S0 or U. U is used to identify unique segments that are data sensitive. A unique segment has no twins (PTR=NOTWIN in the IMS DBD). While a parent segment can have many *types* of unique children, it can have at most one *instance* of each type.

Note: In older releases of the adapter, the SEGTYPE attribute was also used to identify the segment key type. While those SEGTYPE values are still supported by the adapter, new synonyms created using the Web Console or Data Management Console identify these characteristics using the KEYTYPE attribute in the Access File. For information, see *KEYTYPE in IMS* on page 1033.

PARENT in IMS

The PARENT attribute identifies the parent of the segment in the hierarchy. It appears in the PARENT parameter of the SENSEG record in the PCB. The only exception is in the root segment, where the PCB either omits the PARENT parameter or specifies PARENT=0. In the Master File, you can specify the PARENT attribute of the root segment as PARENT= , or you can omit it.

Syntax: How to Specify IMS Field Attributes

Each segment consists of one or more fields. The IMS DBD contains FIELD declarations for all sequence (key) and search fields, but other fields are optional.

If the PCB you are describing contains SENFLD records for a segment, the Master File can view only fields explicitly specified in those SENFLD records.

However, if the PCB does not contain any SENFLD records for a segment, you can describe the entire segment in the Master File. You can get information about sequence and search fields from the DBD. To describe other fields, you may have to refer to an external description of the segment, for example, a COBOL FD.

The Master File need not describe all fields from a segment, but it must include an initial subset of the segment (that is, it must start from the beginning and not contain any gaps).

To describe a field in the Master File, you must specify the primary attributes FIELDNAME, ALIAS, USAGE, and ACTUAL. These attributes are discussed in this topic. Note that the adapter does not support the MISSING attribute.

```
FIELD[NAME]=field,[ALIAS=]alias,[USAGE=]display,[ACTUAL=]imsformat ,$
```

where:

field

Is a 1- to 66-character field name. In requests, the field name can be qualified with the Master File and/or segment name. Although the qualifiers and qualification characters do not appear in the Master File, they count toward the 66-character maximum.

alias

Is the alias for a type of field. Possible values are:

imsfield.KEY, the alias for a field that is an IMS key field. Form the alias by appending the suffix KEY to the name of the IMS field.

imsfield.IMS, the alias for a field that is an IMS search field. Form the alias by appending the suffix IMS to the name of the IMS field.

imsfield.HKY, the alias for a field that is the key of the root segment in an HDAM data source. Form the alias by appending the suffix HKY to the name of the IMS field.

display

Is the server display format for the field.

imsformat

Is the server definition of the IMS field format and length (n).

You can omit the ALIAS, USAGE, and ACTUAL keywords from the field declaration if the values are specified in the standard order (FIELD, ALIAS, USAGE, ACTUAL). For example, the following declarations are equivalent:

```
FIELD = YEAR, ALIAS=, USAGE=A2, ACTUAL=A2,$
FIELD = YEAR, ,A2, A2,$
```

FIELD NAME in IMS

Field names can consist of a maximum of 66 alphanumeric characters. IMS field names are acceptable values if they meet the following naming conventions:

- Names can consist of letters, digits, and underscore characters. Special characters and embedded blanks are not advised.
- The name must contain at least one letter.
- Duplicate field names (the same field names and aliases) within a segment are not permitted.

Since field names appear as default column titles for reports, select names that are representative of the data.

Note: You can only specify field names in an SQL request. You cannot specify the ALIAS name.

ALIAS in IMS

The ALIAS value in the Master File distinguishes between fields that are defined in the IMS DBD and fields that are not defined to IMS. The adapter uses this information in constructing DL/I calls to IMS.

If a field name in a WHERE clause is a sequence or search field, the adapter may be able to create an SSA that instructs IMS to apply the screening test and return the appropriate records to the server. If the field is not defined in the DBD, the adapter must retrieve all records sequentially from IMS so that the server can screen them.

Note: In certain cases, the adapter can instruct IMS to screen values based on a secondary index. *Segment Redefinition in IMS: The RECTYPE Attribute* on page 1021 describes the technique for taking advantage of a secondary index.

The ALIAS value for a field defined in the DBD is composed of:

- The name of the field as specified in the IMS DBD (1- to 8-characters in length).
- A separation character, the period (.).
- A suffix value that describes whether the field is a sequence field (suffix KEY), a search field (suffix IMS), or the key of the root segment of an HDAM database (suffix HKY).

Except for certain types of control field entries (for example, ORDER and RECTYPE), fields not defined in the DBD should not be assigned ALIAS names. For more information on ORDER and RECTYPE control fields, see *Segment Redefinition in IMS: The RECTYPE Attribute* on page 1021.

USAGE in IMS

The USAGE attribute indicates the display format of the field. An acceptable value must include the field type and length and may contain edit options. The server uses the USAGE format for data display on reports. All standard USAGE formats (A, D, F, I, P) are available.

ACTUAL in IMS

The ACTUAL attribute indicates the server representation of IMS field formats.

For fields defined in the DBD (sequence and search fields), use the format specified in the DBD.

Use the following chart as a guide for describing ACTUAL formats of those fields not defined in the DBD:

COBOL Format	COBOL PICTURE	Bytes of Storage	ACTUAL Format	USAGE Format
DISPLAY	X(4)	4	A4	A4
DISPLAY	S99	2	Z2	P3
DISPLAY	9(5)V9	6	Z6.1	P8.1
DISPLAY	99	2	A2	A2
COMP	S9	4	I2	I1
COMP	S9(4)	4	I2	I4
COMP	S9(5)	4	I4	I5
COMP	S9(9)	4	I4	I9
COMP-1	-	4	F4	F6
COMP-2	-	8	D8	D15
COMP-3	9	1	P1	P1
COMP-3	S9V99	2	P2	P5.2
COMP-3	9(4)V9(3)	4	P4	P8.3
FIXED BINARY(7) (COMP-4)	B or XL1	4	I4	I7

Note: The USAGE lengths shown are minimum values. You can make them larger and add edit options. You must allow space for all possible digits, a minus sign for negative numbers, and a decimal point in numbers with decimal digits.

The cumulative length of all fields, across all segments, cannot exceed 12K bytes.

The following example illustrates the DI21PART Master File that provides access to the DI21PART data source.

```
FILE=DI21PART    ,SUFFIX=IMS,$
SEGNAME=PARTROOT ,PARENT=,SEGTYPE=S0,$
  FIELD=PARTKEY  ,ALIAS=PARTKEY.HKY  ,USAGE=A17   ,ACTUAL=A17   ,$
  FIELD=SKIP1    ,ALIAS=             ,USAGE=A33   ,ACTUAL=A33   ,$
SEGNAME=STANINFO ,PARENT=PARTROOT,SEGTYPE=S0,$
  FIELD=STANKEY  ,ALIAS=STANKEY.KEY  ,USAGE=A2    ,ACTUAL=A2    ,$
  FIELD=SKIP2    ,ALIAS=             ,USAGE=A83   ,ACTUAL=A83   ,$
SEGNAME=STOKSTAT ,PARENT=PARTROOT,SEGTYPE=S0,$
  FIELD=STOCKEY  ,ALIAS=STOCKEY.KEY  ,USAGE=A16   ,ACTUAL=A16   ,$
  FIELD=SKIP3    ,ALIAS=             ,USAGE=A124  ,ACTUAL=A124  ,$
SEGNAME=CYCCOUNT ,PARENT=STOKSTAT,SEGTYPE=S0,$
  FIELD=CYCCKEY  ,ALIAS=CYCCKEY.KEY  ,USAGE=A2    ,ACTUAL=A2    ,$
  FIELD=SKIP4    ,ALIAS=             ,USAGE=A23   ,ACTUAL=A23   ,$
SEGNAME=BACKORDR ,PARENT=STOKSTAT,SEGTYPE=S0,$
  FIELD=BACKEY   ,ALIAS=BACKEY.KEY   ,USAGE=A10   ,ACTUAL=A10   ,$
  FIELD=SKIP5    ,ALIAS=             ,USAGE=A65   ,ACTUAL=A65   ,$
```

Syntax: How to Issue a GROUP Field in IMS

IMS fields can consist of multiple elementary fields. In the Master File, you can break the IMS field into component parts using a GROUP field.

The GROUP record in the Master File describes the combined elementary fields. FIELD records immediately following the GROUP record describe the individual elementary fields.

Each element of the group can have a different format. However, retrieval is more efficient if each USAGE format is of the same type (for example, alphanumeric or packed) as its ACTUAL format; the lengths may differ.

```
GROUP=gname, ALIAS=alias, ELEMENTS=n,$
 FIELD=fld1,,usage1,actual1,$
 .
 .
 .
 FIELD=fldn,,usagen,actualn,$
```

where:

gname

Is the group name. It can be any name that complies with field naming conventions.

alias

Is the IMS field name from the DBD if the group field is a sequence or search field. Possible values are:

imsfield.KEY is the alias for a field that is an IMS key field. Form the alias by appending the suffix KEY to the name of the IMS field.

imsfield.IMS is the alias for a field that is an IMS search field. Form the alias by appending the suffix IMS to the name of the IMS field.

imsfield.HKY is the alias for a field that is the key of the root segment in an HDAM data source. Form the alias by appending the suffix HKY to the name of the IMS field.

Note: The keyword ALIAS is required.

n

Is the number fields in the group.

fld1,...,fldn

Are field names for the individual elements that compose the group.

usage1,...,usagen

Are USAGE formats for the individual elements. For efficient retrieval, each individual USAGE format must be of the same data type as its corresponding ACTUAL format, but their lengths can differ.

actual1,...,actualn

Are ACTUAL formats for the individual elements. For efficient retrieval, each individual USAGE format must be of the same data type as its corresponding ACTUAL format, but their lengths can differ.

Example: Defining a Group Key

The following is an example of a group key definition in the Master File:

```
GROUP=G1, ALIAS=FILEKEY.KEY, ELEMENTS=3 ,$
  FIELD=F1,,A4,A4,$
  FIELD=F2,,P6,P3,$
  FIELD=F3,,I9,I4,$
```

The GROUP in the example describes an IMS key named FILEKEY that is 11 bytes long and consists of a 4-byte alphanumeric field, a 3-byte packed number, and a 4-byte integer.

The ACTUAL length of the GROUP is 11 (4+3+4).

The USAGE length of the GROUP is 16 (4+8+4) because it counts the packed field as 8.

Since the group components are of mixed data types, you must use individual fields in the WHERE expression of the server query.

```
WHERE F1 = ABCD
WHERE F1 BETWEEN A AND B
WHERE F2 = 245
```

If you reference either the group or the first elementary field from the group in your request, the adapter generates qualified SSAs in its DL/I calls for retrieval. Thus, IMS does the screening and returns the segments that pass the screening test back to the server.

However, if you reference an elementary field that is not the first field in the group, the server constructs DL/I calls to retrieve the segments sequentially, and then the server applies the screening test to the returned data.

Note: The adapter does not support a group field within a group field. You may be able to use DEFINE fields in the Master File instead.

Segment Redefinition in IMS: The RECTYPE Attribute

An IMS segment can have multiple definitions. For instance, a segment may contain either shipment or order information, depending on the value of one of its fields. If the field that identifies the type of segment is at the same position and has the same format and length in each redefinition, you can use the RECTYPE attribute to define the different segment types in the Master File.

The record type (RECTYPE) field can be part of the key or of the body of the segment. When you issue a request, you do not have to know which segment definition is called for. The server retrieves the appropriate fields and values based on the value in the RECTYPE field.

In the Master File, you describe the one IMS segment with multiple server segments: a base segment describing the unchanging portion, and a child segment describing each redefinition:

- First define the constant portion of the segment as the base segment; give it the same name as the IMS segment. Include a filler field for the portion that will be redefined. The field that identifies the different types must be in the redefined portion.
- Describe each redefined portion as a child of the base segment. You can give these children any valid segment names, but do not assign them SEGTYPE values. Include a filler field in each child to occupy the positions of fields actually defined in the base segment.

  In each child segment, describe the field that identifies the segment type with FIELDNAME=RECTYPE. The value in the RECTYPE field is the value that identifies the type of segment. For example, the RECTYPE field could contain the value S for a shipment record, or O for an order record. The format of the RECTYPE field can be alphanumeric, integer, or packed.

  Assign the identifying value (for example, S or O) as the ALIAS for the RECTYPE field. If more than one value can identify the same record type, use the ACCEPT attribute instead.

  Describe the remaining fields of each child segment based on its contents and function.

Example: Illustrating an IMS DBD With a Redefined Segment

The following example illustrates an IMS DBD with a redefined segment. The CLIENT segment contains client ID, address, and other client information. The INFO segment contains either shipment information or order information, depending on the value in the INFOTYPE field. If INFOTYPE contains the value S, the segment is a shipment segment. If INFOTYPE contains the value O, the segment is an order segment.

The relevant portions of the DBD are:

```
SEGM NAME=CLIENT,BYTES=(200),PTR=(TWIN),PARENT=0
  FIELD=(CLID,SEQ,U),BYTES=8,START=1,TYPE=C
    .
    .
    .
SEGM NAME=INFO,BYTES=(200),PTR=(TWIN),PARENT=CLIENT
  FIELD=(IKEY,SEQ,U),BYTES=8,START=1,TYPE=C
  FIELD=(INFOTYPE),BYTES=1,START=09,TYPE=C
    .
    .
    .
```

The corresponding Master File represents the IMS INFO segment with three segments:

```
     FILE=IMS1,SUFFIX=IMS
      SEGNAME=CLIENT,SEGTYPE=S0
        FIELD=F1,CLID.KEY,A8,A8,$
1.    SEGNAME=INFO   ,SEGTYPE=S0,PARENT=CLIENT,$
        FIELD=F3,IKEY.KEY,A8,A8,$
        FIELD=,,          A20,A20,$
2.    SEGNAME=SHIP,SEGTYPE=,PARENT=INFO,$
        FIELD=,,          A8,A8,$
        FIELD=RECTYPE,S,  A1,A1,$
        FIELD=SHIPDATE,,  A6,A6,$
          .
          .
          .
        other shipment info
3.    SEGNAME=ORDER,SEGTYPE=,PARENT=INFO,$
        FIELD=,,         A8,A8,$
        FIELD=RECTYPE,O, A1,A1,$
        FIELD=ORDERDATE,,A6,A6,$
          .
          .
          .
        other order info.
```

Note:

1. The base segment is named INFO, like the IMS segment. It contains the key field. The redefined portion is described as a filler field.
2. The SHIP segment describes the shipment record type. The field that corresponds to the IMS INFOTYPE field has FIELDNAME=RECTYPE and ALIAS=S.
3. The ORDER segment describes the order record type. The field that corresponds to the IMS INFOTYPE field has FIELDNAME=RECTYPE and ALIAS=O.

Notice that each child segment has a filler for the key field defined in the base segment.

Syntax: How to Establish Multiple RECTYPE Values in IMS

If multiple values identify the same record type (for example, S or T for a shipment record), use the ACCEPT attribute to enumerate the list or range of acceptable values. In this case, define the ALIAS value as blank.

```
FIELDNAME=RECTYPE, ALIAS=, USAGE=usage, ACTUAL=actual,
   ACCEPT=val1 [OR] val2 [[OR] ...valn],$
```

or

```
FIELDNAME=RECTYPE, ALIAS=, USAGE=usage, ACTUAL=actual,
   ACCEPT=val1 to val2
```

where:

val1,val2,valn

Defines a list or range of values that identifies the record type. A list can be continued on more than one line. Enclose values that contain embedded blanks or special characters within single quotation marks.

The following examples illustrate the ACCEPT attribute:

```
ACCEPT=AAA TO RRR
ACCEPT=136 TO 1029
ACCEPT=RED OR WHITE OR BLUE
ACCEPT=RED WHITE BLUE
ACCEPT=6 OR 11 OR 922 OR 1000
ACCEPT=RED WHITE 'GREEN GREY'
```

Repeating Data in IMS Fields: The OCCURS Segment

In an IMS data source, segments can have repeating fields or repeating groups of fields. The number of repetitions:

- Can be a fixed number.

- Can depend on the value of a field from the parent segment or from the non-repeating portion of the variable segment.
- May have to be calculated from the segment length.

In the Master File, you define multiple segments to describe one IMS variable length segment:

- Define the fixed (single-occurrence) portion of the IMS segment as the base segment. Give it the same name as the IMS segment.
- Define each repeating field or group of fields from the IMS segment as a child segment whose parent is the base segment. The child segment definition has no SEGTYPE, but it includes the OCCURS attribute to specify how many times the field repeats.
- Define the ORDER field in the OCCURS segment if you need to associate a sequence number with each occurrence.

The OCCURS segment is a virtual segment (it does not physically exist) that describes the repetitions to the server. Permissible values for the OCCURS attribute are as follows:

OCCURS=	Description
n	The number of times the field repeats in the segment.
fieldname	The name of a field that contains a value indicating the number of times the field repeats in the segment. The repeating field must be at the end of the segment.
VARIABLE	Indicates that the number of repetitions must be computed from the length of the segment. In this case, the segment must contain a counter field as its first field; the counter field alias in the Master File must be IMS*name*.CNT. The repeating field must be at the end of the segment.

With a fixed number of occurrences, it is possible for the repeating field to be located between other fields in the segment rather than at the end of the segment. In this case, you must define a place-holder field at its position in the base segment. Then, in the OCCURS segment, identify the location of the repeating field by specifying the name of the place-holder field as the POSITION attribute.

Syntax: How to Describe Repetitions to the Server With an OCCURS Segment

```
SEGNAME=occseg, PARENT=imsseg, OCCURS=nfield                ,$
SEGNAME=occseg, PARENT=imsseg, OCCURS=n [,POSITION=posfield]  ,$
SEGNAME=occseg, PARENT=imsseg, OCCURS=VARIABLE              ,$
```

where:

occseg

Is the name of the OCCURS segment. It can be any valid segment name.

imsseg

Is the name of the base segment. It must be the IMS segment name.

nfield

Is the name of a field in the parent or non-repeating portion of the segment whose value is the number of times that the group repeats. You must define this field in the Master File whether or not it is a search field defined in the DBD.

n

Is the fixed number of times that the group repeats in the segment. It is an integer value from 1 to 4095.

posfield

Signals that the repeating field is embedded within the base segment rather than occurring at the end, and names a field in the base segment that marks the starting position of the repeating field.

VARIABLE

Indicates that the length of the repeating segment varies and that the number of occurrences can be computed from each segment. In this case, the (base) segment must contain a counter field as its first field; the counter field's alias value must be

IMS*name*.CNT

where:

IMS*name*

Is the name of the field in the IMS DBD.

In the IMS DBD, a variable length segment differs from a fixed length segment only in the BYTES parameter. For variable length segments, the BYTES parameter consists of two values: the maximum and minimum number of bytes. IMS cannot search for values among the repetitions within a segment. Therefore, in any request that references a field in a repeating group, the server searches and screens the OCCURS segments, not IMS.

Syntax: How to Describe the ORDER Field in IMS

Sometimes the sequence of fields within an OCCURS segment is significant. For example, each instance of the repeating field may represent one quarter of the year, but the segment may not have a field that specifies the quarter to which it applies.

ORDER is an optional counter used to identify the sequence number within a group of repeating fields. Specify it when the order of data is important. The ORDER field does not represent an existing field in the data source; it is used only for internal processing.

The ORDER field must be the last field described in the OCCURS segment.

```
FIELDNAME=name, ALIAS=ORDER, USAGE=In, ACTUAL=I4 ,$
```

where:

name

Is any valid field name.

I*n*

Is an integer format.

Note:

- The ALIAS value must be ORDER.
- The ACTUAL format must be I4.

The ORDER field must be the last field defined in the OCCURS segment.

In requests, you can use the value of the ORDER field. You can also specify a DEFINE statement in the Master File to translate it to more meaningful values. For example:

```
DEFINE QTR/A3 = DECODE ORDER(1 '1ST' 2 '2ND' 3 '3RD' 4 '4TH');
```

A subsequent request could include

```
SELECT TOT.TAXES WHERE QTR=1
```

or:

```
SELECT QTR,BALANCE,INTEREST
```

Example: Issuing OCCURS=n

In the following example, the IMS segment, IMS1, includes a group (consisting of the two fields MONTH and AMOUNT) that repeats 12 times. The COBOL FD for the segment is:

```
01  IMS1
    05  ACCOUNT  PIC X(9)
    05  TYPE     PIC XXX
    05  PAYMENT OCCURS 12 TIMES
        10 MONTH PIC 99
        10 AMT   PIC S9(3)V(99)COMP-3
```

The Master File uses two segments to describe this IMS variable length segment:

```
1. SEGNAME=IMS1,PARENT=,SEGTYPE=S0
     FIELD=ACT_NUM,ALIAS=ACCOUNT.KEY,A9,A9,$
     FIELD=TYPE,ALIAS=,A3,A3,$
2. SEGNAME=OCC1,PARENT=IMS1,OCCURS=12
     FIELD=MM, ALIAS=,A2,A2,$
     FIELD=AMT,ALIAS=,P6.3,P3,$
```

1. Segment IMS1 is the base segment. It has the same name as the IMS segment and describes the two non-repeating fields: ACT_NUM and TYPE.
2. The OCCURS segment, OCC1, identifies IMS1 as its parent. It has no SEGTYPE, and it includes the OCCURS attribute. The two repeating fields are described in this segment.

In the following example, the repeating group is not at the end of the segment. It is embedded in the segment before the LNAME field. The COBOL FD for this situation is:

```
01  IMS1
    05  ACCOUNT PIC X(9)
    05  TYPE    PIC XXX
    05  PAYMENT OCCURS 12 TIMES
        10 MONTH PIC 99
        10 AMT   PIC S9(3)V(99)COMP-3
    05  LNAME   PIC X(20)
```

The Master File must include LNAME in the base segment. It must also describe where the repeating fields fit into the base segment by defining a place-holder field before LNAME, equal to the length of the 12 occurrences, and by pointing to the place-holder field with the POSITION attribute:

```
    SEGNAME=IMS1,PARENT=,SEGTYPE=S0
     FIELD=ACT_NUM,ALIAS=ACCOUNT.KEY,A9,A9,$
     FIELD=TYPE,ALIAS=,A3,A3,$
1.   FIELD=HOLDIT,ALIAS=,A60,A60,$
     FIELD=LNAME,ALIAS=,A20,A20,$
2.  SEGNAME=OCC1,PARENT=IMS1,OCCURS=12,POSITION=HOLDIT
     FIELD=MM,ALIAS=,A2,A2,$
     FIELD=AMT,ALIAS=,P6.3,P3,$
```

1. The HOLDIT field is the place holder for the repeating group in the base segment (IMS1). Since the repeating group consists of 12 occurrences, each of which is 5 bytes long (A2 and P3, described in segment OCC1), the HOLDIT field is defined as A60.
2. The attribute POSITION=HOLDIT in the OCCURS segment declaration describes where the repeating group is located in the actual (base) segment.

Example: Issuing OCCURS=fieldname

In the next example, the number of occurrences is specified by the value in the TIMES field. The following COBOL FD describes this situation:

```
01  IMS1
    05  ACCOUNT PIC X(9)
    05  TYPE    PIC XXX
    05  TIMES   PIC S999  COMP-3
    05  PAYMENT OCCURS DEPENDING ON TIMES
        10 MONTH PIC 99
        10 AMT   PIC S9(3)V(99)COMP-3
```

The Master File attribute, OCCURS=TIMES, identifies the TIMES field as containing the number of repetitions. The Master File also defines the optional ORDER field as the last field in the OCCURS segment:

```
    SEGNAME=IMS1,SEGTYPE=S0
     FIELD=ACT_NUM,ALIAS=ACCOUNT.KEY,A9,A9,$
     FIELD=TYPE,ALIAS=,A3,A3,$
     FIELD=TIMES,ALIAS=,P4,P2,$
1.  SEGNAME=OCC1,PARENT=IMS1,OCCURS=TIMES
     FIELD=MM,ALIAS=,A2,A2,$
     FIELD=AMT,ALIAS=,P6.3,P3,$
2.   FIELD=WHICH,ALIAS=ORDER,I4,I4,$
```

1. The attribute OCCURS=TIMES identifies the value in the TIMES field as the number of instances of the repeating group.
2. The field named WHICH is the optional ORDER field (ALIAS=ORDER). It is an internal counter defined as the last field in the OCCURS segment. It associates a sequence number with each occurrence of the repeating group. With the ORDER field defined, a request can include a test that selects a specific occurrence. For example:

```
   WHERE WHICH = 3
```

Example: Issuing OCCURS=VARIABLE

This example describes a segment in which the number of occurrences must be calculated from the length of the segment. The first field in the segment must be a 2-byte counter field that contains the true length of the segment and is defined to IMS in the DBD. The COBOL FD for this variable length segment is:

```
01  IMS1
    05  COUNTER PIC 99 COMP
    05  ACCOUNT PIC X(9)
    05  TYPE    PIC XXX
    05  PAYMSCHED OCCURS 1 TO 12 TIMES
        10 MONTH PIC 99
        10 AMT   PIC 59(3)V(99)COMP-3
```

The Master File must specify OCCURS=VARIABLE and must describe the counter field with the attribute

```
ALIAS=IMSname.CNT
```

```
    SEGNAME=IMS1,SEGTYPE=S0
1.   FIELD=COUNTFLD,ALIAS=COUNTER.CNT,I2,I2,$
     FIELD=ACT_NUM,ALIAS=ACCOUNT.KEY,A9,A9,$
     FIELD=TYPE,ALIAS=,A3,A3,$
2.  SEGNAME=OCC1,PARENT=IMS1,OCCURS=VARIABLE
     FIELD=MM,ALIAS=,A2,A2,$
     FIELD=AMT,ALIAS=,P6.3,P3,$
```

1. The 2-byte counter field must be the first field in the base segment. Its alias is formed by appending the suffix CNT to the field name defined in the IMS DBD:

   ```
   ALIAS=COUNTER.CNT
   ```

2. In the OCCURS segment definition, the attribute OCCURS=VARIABLE indicates that the first field defined in the Master File contains the segment length and that the number of repetitions must be calculated from this length.

Syntax: How to Redefine Fields in IMS Databases

Support is provided for redefining record fields in IMS databases. This allows a field to be described with an alternate layout.

Within the Master File, the redefined field(s) must be described in a separate unique segment (SEGTYPE=U) using the POSITION=*fieldname* and OCCURS=1 attributes.

```
SEGNAME=segname,SEGTYPE=U,PARENT=parent,
OCCURS=1,POSITION=position ,$
```

where:

segname

Is the segment name.

parent

Is the name of the parent segment.

position

Is the field name of the field being redefined.

A one-to-one relationship is established between the parent record and the redefined segment. The following example illustrates redefinition of the IMS structure described in the COBOL file description:

```
01 ALLFIELDS.
  02 FLD1   PIC X(4).
  02 FLD2   PIC X(4).
  02 RFLD2  PIC 9(5)V99 COMP-3 REDEFINES FLD2.
  02 FLD3   PIC X(8).

FILENAME=REDEF, SUFFIX=IMS,$
  SEGNAME=ONE, SEGTYPE=S0,$
    GROUP=RKEY, ALIAS=KEY  ,USAGE=A4   ,ACTUAL=A4     ,$
      FIELDNAME=FLD1,      ,USAGE=A4   ,ACTUAL=A4     ,$
      FIELDNAME=FLD2,      ,USAGE=A4   ,ACTUAL=A4     ,$
      FIELDNAME=FLD3,      ,USAGE=A8   ,ACTUAL=A8     ,$
    SEGNAME=TWO, SEGTYPE=U, POSITION=FLD2, OCCURS=1, PARENT=ONE ,$
      FIELDNAME=RFLD2,     ,USAGE=P8.2 ,ACTUAL=Z4     ,$
```

The redefined fields may have any user defined name. ALIAS names for redefined fields are not required.

Use of the unique segment with redefined fields helps avoid problems with multipath reporting.

Note:

- Redefinition is a read-only feature and is used only for presenting an alternate view of the data. It is not used for changing the format of the data.
- A field that is being redefined must be equal in length to the field that it is redefining (same actual length).
- For integer and packed fields, you must know your data. Attempts to print numeric fields that contain alpha data will produce data exceptions or errors converting values.

- More than one field can be redefined in a segment.

Access File Attributes

Access Files store database access information used to translate report requests into the required IMS direct calls. For example, the Access File can contain the PSB name, the PCB name, the type of PCB, segment key types, and secondary index information.

In older versions of the adapter, some of these attributes were specified in the Master File instead of the Access File, and the Access File was optional. While those Master Files are still supported by the adapter, new synonyms created using the Web Console or the Data Management Console will have both a Master File and Access File, and the Access File will contain any of these attributes needed for accessing the IMS data source.

An Access File consists of 80-character records in comma-delimited format. A record in an Access File contains a list of attributes and values, separated by commas and terminated with a comma and dollar sign (,$). This list is free-form and spans several lines if necessary. You can specify attributes in any order.

The server reads blank lines, and lines starting with a dollar sign in column one, as comments.

Procedure: How to Select a PSB

You have two options for selecting a PSB within the session:

- You can issue the IMS SET PSB command in your server profile, or in a stored procedure.
- You can identify the PSB in the Access File. Each Access File corresponds to one Master File. It identifies the PSB associated with its corresponding Master File.

If you use an Access File, the adapter identifies the appropriate PSB when you reference a Master File in a request. The selection is automatic and transparent to you.

Syntax: How to Specify Access File Attributes

Each Access File will contain six or more attributes.

```
PSB=psbname,PCBNUMBER= pcb_number,PL1={NO|YES},WRITE={YES|NO},$
SEGNAME=segment_name, KEYTYPE=keytype,[NON_KEYED=NOMATCH,]$
ALTPCBNAME=index_name  , ALTPCBNUMBER=index_PCB_number,$
```

where:

psbname

Is the name of the PSB to use. If the PSB does not exist, the following message is (generated) displayed:

```
(EDA4261) PSB MEMBER NOT FOUND: psbname
```

pcb_number

The position within the PSB that points to the database to be processed.

PL1

Indicates whether the PSB was generated with LANG=(PL/I, COBOL or Assembler). YES indicates PL/I. NO indicates COBOL or Assembler.

WRITE

YES allows SQL update for this database.

NO does not allow SQL update for this database and is the default.

segname_name

Are the segment name(s) defined in the database definition.

keytype

Identifies the segment characteristics.

Possible values are:

S0 indicates that the segment is data sensitive and has no key.

S or S1 indicates that the segment is data sensitive and has a non-unique key.

S2 indicates that the segment is data sensitive and has a unique key.

SH or SH1 indicates that the segment is key sensitive and has a non-unique key.

SH2 indicates that the segment is key sensitive and has a unique key.

NON_KEYED=NOMATCH

Inserts records into a non-keyed child segment without first doing a MATCH on the segment. With this attribute, you can insert a segment instance containing data based on a Master File different from the one used to insert prior instances. Without this attribute, you would get a FOC200 message if the data being inserted did not conform to the original Master File, and the record would not be inserted.

index_name (Optional)

Identifies a secondary index database defined by the 'Procseq=' option within the PSB.

index_PCB_number (Optional)

Identifies the PCB number of the indexed database.

The member name of an Access File must be the same as the member name of the corresponding Master File.

Note: All participating files in a join must use the same PSB. Any attempt to join files that require different PSBs generates the following message:

```
(EDA4295) ACCESS POINTS TO DIFFERENT PSBS IN JOIN
```

Reference: KEYTYPE in IMS

The KEYTYPE attribute:

- Identifies the characteristics of the segment key field. A segment can have a unique key, a non-unique key, or no key.

  If a segment has a unique key, at least one FIELD record in the DBD must specify NAME=(fieldname,SEQ,U) or NAME=(fieldname,SEQ). Similarly, if the segment has a non-unique key, at least one FIELD record in the DBD must specify NAME=(fieldname,SEQ,M). If no FIELD record in the DBD specifies a SEQ attribute, the segment has no key.

  The characteristics of the segment key determine the types of SSAs and the number of DL/I calls the adapter must issue to satisfy a retrieval request. To handle keys made up of multiple fields, describe the multiple fields as a group in the Master File (for details, see *How to Issue a GROUP Field in IMS* on page 1019).

- Identifies whether the data from the segment can be retrieved (data sensitive) or if only the segment key is accessible (key sensitive). For a key sensitive segment, the SENSEG record in the PCB includes the parameter PROCOPT=K. Key sensitive segments are used for access to lower-level segments.

The following chart lists the valid KEYTYPE values.

KEYTYPE	Definition	PROCOPT=K In PCB?	NAME= From DBD
`S0`	Data sensitive, no key	No	(name)
`S or S1`	Data sensitive, non-unique key	No	(name,SEQ,M)
`S2`	Data sensitive, unique key	No	(name,SEQ,U) or (name,SEQ)

KEYTYPE	Definition	PROCOPT=K In PCB?	NAME= From DBD
SH or SH1	Key sensitive, non-unique key	Yes	(name,SEQ,M)
SH2	Key sensitive, unique key	Yes	(name,SEQ,U) or (name,SEQ)

Example: Sample Access File for DI21PART

The following is a sample Access File corresponding to the DI21PART Master File.

```
PSB=DI21PSB, WRITE=NO PCBNUMBER=2, PL1=NO,,$
SEGNAME=PARTROOT,  KEYTYPE=S2,$
SEGNAME=STANINFO,  KEYTYPE=S2,$
SEGNAME=STOKCOUNT, KEYTYPE=S2,$
SEGNAME=CYCCOUNT,  KEYTYPE=S2,$
SEGNAME=BAKORDR,   KEYTYPE=S2,$
```

Describing Secondary Indexes in IMS

If you want to access a segment through a field in a segment that is not its sequence field (primary key), IMS provides the option of creating a secondary index on the field. In some situations, using a secondary index improves performance. The secondary index is itself a separate data source. Each of its records contains a value of the field to be indexed and a pointer to the target segment of the data source record containing that value.

When using a secondary index, IMS locates a record by first reading the *index* data source to retrieve the appropriate pointer and then using the pointer to read the *data* source.

If a PCB includes the parameter

PROCSEQ=*index*DBD*name*

the named index is used as the main entry point into the data source.

One Master File and Access File can describe all primary and secondary indexes for a data source. Then, given a request, the adapter can examine all record selection tests to determine the best access path into the data source. The adapter can take advantage of this Auto Index Selection feature if:

- The PSB includes a PCB for each index you may need to access. Each such index PCB must contain a

  PROCSEQ=*index*DBD*name*

parameter that identifies the index DBD.

- The index targets the root segment in the Master File.

In the Master File, prior to the secondary index definitions, you must describe the entire segment of the data source. Every field listed in the DBD is an IMS sequence field or search field, and each secondary index is based on one or more of these fields. You must assign each secondary index field its appropriate alias, as described in *How to Specify IMS Field Attributes* on page 1015.

Note: IMS allows for system-defined sub-sequence fields to make an index unique. The Master File can completely ignore the presence and length of such fields.

Reference: **Using an IMS Secondary Index**

When you create a synonym, information about secondary indexes is placed in the Access File. No auxiliary virtual fields (that is, SKY groups/fields) are created in the Master File.

Note: Existing .sky field suffix-based definitions are supported to ensure compatibility.

Two segments belonging to the same root path might be connected by secondary indexes:

- A target segment has an associated special virtual search field (described in the Access File) to be used in the qualified SSA.
- A source segment has the real base fields to be used in the screening predicates to find the target segment instances.

One target segment may have many secondary indexes based on search fields from different source segments. The secondary index can be based on up to five base fields from the same segment.

Each PCB can be associated with only one index: primary or secondary. A secondary index is defined in the PROCSEQ parameter. When the synonym is created, a primary PCB number is chosen and placed in the PCBNUMBER attribute in the Access File PSB declaration. If the PSB contains several PCBs that define identical hierarchies, the primary PCB number is selected according to following rules:

- If all eligible PCBs have a PROCSEQ parameter, the primary PCB number is taken from the PCB you selected when creating the synonym.

  The root segment is determined, and hierarchical entries processed, in the sequence corresponding to the primary PCB secondary index when an area sweep is performed.
- If at least one of the eligible PCBs does not have a PROCSEQ parameter, the primary PCB number corresponds to the last encountered PCB without a PROCSEQ.

The root is processed in the sequence corresponding to the physical sequence of segment instances for the non-keyed segment, and in the key sequence for key segments when an area sweep is performed.

Sequential numbers of all other PCBs of identical hierarchies associated with the same DBD are stored in the ALTPCBNUMBER attribute in the XDFLD Access File declaration.

Each DBD may be associated with any number of PCBs. Each PCB may have a PROCSEQ parameter to indicate an index key. The segment to which this key refers becomes the tree root segment. Therefore, it is possible to have different hierarchical structures associated with the same database. All identical hierarchies (the only difference is in the PROCSEQ key name) are described by the same Master File. Different Master Files are generated for the various inverted hierarchies.

Access File XDFLD declarations are used to describe secondary indexes. There is a one-to-one relationship between XDFLD statements in the Access File and PROCSEQ parameters in the PCB.

There are two types of XDFLD declarations:

- The first type describes secondary indexing based on PROCSEQ.

  The XDFLD belongs to the tree root segment and must have an ALTPCBNUMBER parameter that refers to the appropriate PCB number. Each PROCSEQ parameter can represent an identical hierarchical structure. Multiple PROCSEQ parameters generate multiple XDFLD declarations in the Access File. Only one such XDFLD statement is needed to build a qualified SSA in the request.

- The second type describes secondary indexing based on the SENSEG INDICES parameter.

  A SENSEG INDICES parameter may be associated with any segment and must not have an ALTPCBNUMBER attribute in the Access File.

  The Access File may contain XDFLD declarations produced from information that is found in the INDICES parameter of the SENSEG macro in a PCB definition. Up to 32 different XDFLD declarations associated with a segment can be built from one SENSEG macro. Any number of such XDFLD declarations might be used to build a qualified SSA in the request. Both types of secondary indexes can be used simultaneously in the qualified SSA in the request. For related information, see *Defining Subsets of DBD Segments and IMS Fields in Segments* on page 1012.

Secondary indexes are physically stored in separate index databases. These databases are referenced by the PROCSEQ and INDICES parameters. One index database can be used to store up to 16 secondary indexes. Such a database, and the related indexes, is referred to as a shared secondary index.

Example: Describing a Shared Secondary Index DBD

You can use information from a shared secondary index DBD to create XDFLD declarations. The following files illustrate the required entries.

DBD and PSB

```
      DBD NAME=DIX1DBD,ACCESS=(HIDAM,VSAM)
      DATASET  DD1=DIX1KAPL,DEVICE=3380

Access File:

```
PSB=DIX1PSB, WRITE=NO, PCBNUMBER=5, PL1=NO, $
 SEGNAME=STOKSTAT, KEYTYPE=S2, $
 XDFLD=CYCLNUMX, SRCH=CNMB1/CNMB3/CNMB2, BASESEG=CYCCOUNT,ALTPCBNUMBER=5, $
 XDFLD=CYCLVALX, SRCH=CYCLVALU, BASESEG=CYCCOUNT, ALTPCBNUMBER=6, $
 SEGNAME=CYCCOUNT, KEYTYPE=S2, $
 SEGNAME=PARTROOT, KEYTYPE=S2, $
 XDFLD=PARTNAMX, SRCH=PARTNAME, $
 XDFLD=PARTFILX, SRCH=PARTFIL1, $
```

This example uses four secondary indexes:

- **PARTNAMX** is the secondary index used to find the segment PARTROOT by the value of the PARTNAME field. This is a SENSEG-type secondary index. Target and source segments are in the same PARTROOT.
- **PARTFILX** is the secondary index used to find the segment PARTROOT by the value of the PARTFIL1 field. This is a SENSEG-type secondary index. Target and source segments are in the same PARTROOT.
- **CYCLNUMX** is the secondary index used to find the segment STOKSTAT by the value of the CNMB1, CNMB3 and CNMB2 fields. This is a PROCSEQ-type secondary index. The target segment is STOKSTAT; the source segment is CYCCOUNT.
- **CYCLVALX** is the secondary index used to find the segment STOKSTAT by the value of the CYCLVALU field. This is PROCSEQ-type secondary index. The target segment is STOKSTAT; the source segment is CYCCOUNT.

Definition description:

1. Secondary index description associated with the target segment.
2. XDFLD parameter defines the secondary index name used to build the SSA.
3. BASESEG parameter defines the source segment name (if it is not the target segment).
4. SRCH parameter defines the names of one or more (up to five) base fields, and their order in the secondary index.

Note: A qualified SSA is built for the target segment if at least one eligible screening condition is provided for the associated primary key, search field, or secondary key base source field.

Example: The PATDB01 Sample Database

The PATDB01 database has a primary index because it is a HIDAM database. It is also defined with three secondary indexes.

Five DBDs are associated with PATDB01: the DBD for the database, the DBD for the primary index, and one DBD for each of the three secondary indexes.

Database DBD for PATDB01

PATDB01 DBD:

```
  PRINT NOGEN

Describing a Partition to the Server

IMS limits the size of its data sources. A site that needs a larger data source may be able to create several smaller data sources by partitioning the large data source based on root key values.

Using extended Access File attributes, you can describe a partition to the server, describe how to concatenate the parts, and assign a name to the concatenated PCB. When you issue a request, you can report from the concatenated PCB name or from any of the individual partitions, depending on the file name you reference in the request.

Syntax: How to Describe a Partition in the Access File

A partition assigns each record to a specific data source depending on its root key value. The first partition contains records with the lowest key values. The next partition contains records with higher key values, and so on. The last partition contains records with the highest key values. Each partition is a separate IMS data source and, therefore, has a separate PCB in the PSB.

To describe the key range in each partition to the server, add the LOWVALUE and HIGHVALUE attributes to the appropriate PCB records in the Access File.

```
PCBNAME=mfdname,PCBTYPE=DB,LOWVALUE={value1|0},HIGHVALUE={value2|FF},$
```

where:

mfdname

Is the name of the Master File for one partition of the large data source. Since the partition is a separate data source with its own DBD, it needs its own PCB and Master File.

value1

Is the lowest key value, in alphanumeric format, in the partition accessed with Master File *mfdname*. 0 is the default value.

value2

Is the highest key value, in alphanumeric format, in the partition accessed with Master File *mfdname*. Hexadecimal FF is the default value.

Note:

- The LOWVALUE and HIGHVALUE attributes are ignored if you do not define a corresponding concatenation of the PCBs.
- The number of partitions you can define for a data source is limited by the number of PCBs in the PSB.
- The partitioning field must be the key of the root segment.
- The partitioning field must have an alphanumeric format.

If the partitioning field is a group composed of multiple subfields, each subfield value must be alphanumeric, and you must specify the concatenated subfield values in the LOWVALUE and HIGHVALUE attributes. For example, if the root key low value is composed of F1=AAAA, F2=88, and F3=BBB, then LOWVALUE=AAAA88BBB.

Describing a Concatenated PCB

In an Access File, you can concatenate individual PCBs by assigning a name to the concatenation and issuing a request against it.

The PCBs that you concatenate do not have to be partitioned, that is, their Access File records do not have to include the LOWVALUE and HIGHVALUE attributes. However, if they do include the partitioning information, the adapter can examine the request and determine which PCBs satisfy the request. Without the partitioning information, the adapter must access every PCB that participates in the concatenation.

Syntax: **How to Describe a Concatenated PCB in the Access File**

The format of the Access File for the Adapter for IMS to provide extended support for concatenated databases is as follows:

1. The CONCATPCB statements provide the PCB number and the low and high value range for the root segment key.

   For example:

```
CONCATPCB=4,LOWVALUE=0,HIGHVALUE=0, $
CONCATPCB=6,LOWVALUE=1,HIGHVALUE=1, $
.............................................................
CONCATPCB=12,LOWVALUE=9,HIGHVALUE=9, $
```

2. The CONCPOSITION statement provides root segment key substring information. The substring value is compared with the key ranges defined in the CONCATPCB statements. Positions in the key are counted from 0 for the substring operation.

The key value is converted to alphanumeric format prior to the substring operation. The key format is taken from the ACTUAL description. A Packed or Zoned format number is processed as an unsigned one.

Conversion rules for the Packed format:

- Result buffer size for Pn is n*2-1 bytes.
- Converted number is adjusted to the right in the buffer with the leading 0.

Conversion rules for the Integer format:

- Only I1, I2, and I4 formats are supported.
- Result buffer size for I1 is 3 bytes; I2 is 5 bytes; I4 is 10 bytes.

For example:

```
CONCPOSITION=1,LENGTH=1, $
```

Example: **Describing a HDAM Concatenated PCB**

```
FILENAME=HDAM0, SUFFIX=IMS     , $
  SEGMENT=LANGUAGE, SEGTYPE=S0, $
    FIELDNAME=EMPL6, ALIAS=EMPL6.HKY, USAGE=P8,  ACTUAL=P4, $
    FIELDNAME=LANG6,  ALIAS=LANG6.IMS, USAGE=A15, ACTUAL=A15, $

PSB=PIHDPSB,PCBNUMBER= 4,PL1=NO,WRITE=NO,$
SEGNAME=LANGUAGE, KEYTYPE=S1  ,$
CONCATPCB=4,LOWVALUE=1,HIGHVALUE=1, $
CONCATPCB=6,LOWVALUE=2,HIGHVALUE=2, $
CONCATPCB=8,LOWVALUE=3,HIGHVALUE=3, $
CONCPOSITION=4,LENGTH=1, $
```

Note: PCBNUMBER in the PSB statement refers to the PCB associated with the root segment.

In the following request, we associate the 5th digit in the key (offset 4 in the key buffer) with the PCB to schedule.:

```
TABLE FILE HDAM0
PRINT *
WHERE EMPL6 EQ 9336
END
```

PCB number 8 will be used for the numeric qualifier 9336. The extracted value is 3 (since packed number 9336 is unpacked to the 7 bytes buffer and the result value is 0009336).

Example: Describing a HIDAM Concatenated PCB

EMPDB01, EMPDB02, and EMPDB03 are HIDAM data sources that illustrate partitioning and concatenation of PCBs in the Access File. The following topics illustrate:

- The EMPDB01, EMPDB02, and EMPDB03 DBDs for the three partitions of the data source, and, since these are HIDAM data sources, the EMPDBIX1, EMPDBIX2, and EMPDBIX3 DBDs for the index data sources.
- A PSB with three PCBs, each corresponding to one partition of the data source.
- The EMPDB01, EMPDB02, and EMPDB03 Master Files for the individual partitions, and the EMPDBJ Master File for the concatenation.
- The Access File corresponding to the PSB. It includes the LOWVALUE and HIGHVALUE attributes for each PCB and the CONCATNAME record to define the concatenation.

EMPDB01 DBD

Data source DBD:

Example: **Concatenating Partitioned PCBs**

The following example illustrates how to concatenate partitioned PCBs:

```
PSB=EMPPSBJ, WRITE=NO, PCBNUMBER=4, PL1=NO, $
 SEGNAME=EMPINFO, KEYTYPE=S2, $
PSB=EMPPSBJ, WRITE=NO, PCBNUMBER=5, PL1=NO, $
PSB=EMPPSBJ, WRITE=NO, PCBNUMBER=6, PL1=NO, $
CONCATPCB=4, LOWVALUE=000000001, HIGHVALUE=000001667, $
CONCATPCB=5, LOWVALUE=000001668, HIGHVALUE=000003334, $
CONCATPCB=6, LOWVALUE=000003335, HIGHVALUE=000005000, $
```

Consider the following request. (The key field is named SSNALPHA):

```
SELECT SSNALPHA ...
FROM EMPDBJ
WHERE SSNALPHA = '000001775';
```

The adapter satisfies the request using the EMPDB02 PCB only. If the WHERE clause had requested key values less than 000001775 (rather than equal to 000001775), the adapter would have used the EMPDB01 and EMPDB02 PCBs.

Note:

- If a retrieval request has no WHERE clause, or if the WHERE clause references a non-key field, the adapter accesses all PCBs.
- If any PCB listed in a concatenation lacks the LOWVALUE and HIGHVALUE key range specification, that PCB always participates in the retrieval.

WebFOCUS Reporting With IMS

You can issue any SQL or TABLE request through the Adapter for IMS. However, those requests whose record selection criteria can be applied at the IMS level (with qualified SSAs on .KEY, .IMS, or .HKY fields) result in many fewer DL/I calls and I/O operations than unoptimized requests. They can achieve performance improvements measured in orders of magnitude.

Note: Since IMS does not support the concept of missing data, all fields are considered not missing.

These topics include sample requests with corresponding trace results. You enable traces through Diagnostics on the home pane. In the trace, you get a dump of the SSA buffer setup for each request. For example, the following request contains a selection test on the SEQFIELD search field in the PATINFO segment of the PATDB01 data source:

```
SQL
SELECT LAST_NAME, FIRST_NAME, SEQFIELD, SALARY, SSN
FROM PATDB01
WHERE SEQFIELD = '100000' OR
      SEQFIELD = '100001'
END
```

It produces the following SSA in the trace file:

```
15.13.55 DU D7C1E3C9 D5C6D640 5C604DE2 C5D8C6C9      *PATINFO *-(SEQFI*
15.13.55 DU C5D3C47E 40F1F0F0 F0F0F04E E2C5D8C6      *ELD= 100000+SEQF*
15.13.55 DU C9C5D3C4 7E40F1F0 F0F0F0F1 5D40          *IELD= 100001)   *
```

The output is:

```
LAST_NAME  FIRST_NAME  SEQFIELD  SALARY   SSN

ROSANO     ANDRE       100000    1000.00  197548679
LOVELACE   LARRY       100001    1001.00  197548680
```

Note:

- The dump has a left side and a right side. The left side shows the hexadecimal values in the memory locations. The right side, delimited by *'s, contains the corresponding alphanumeric characters.

  Since not all hexadecimal values represent printable alphanumeric characters, those parts of the dump that correspond to non-printable characters appear as blanks on the right side. In particular, if a comparison value in an SSA is a packed number, it appears as blank on the right-hand side of the dump. In this example, the comparison values are alphanumeric, and therefore they appear.

- The logical operator AND is represented by an asterisk (*) in the SSA, and the logical operator OR is represented by a plus sign (+).

- The field names in the SSA are the alias names from the Master File, since these are the IMS names for the fields.

The SSA always includes the segment name. What distinguishes an optimized request from an unoptimized request is whether the SSA is qualified; a qualified SSA includes the selection test from the request, as in the previous example. An unqualified SSA contains the segment name with no selection criteria.

Whenever possible, the adapter translates screening conditions from the SQL request into qualified SSAs. However, not all server screening conditions can be translated into SSAs. Such conditions are still applied, but by the server, rather than by IMS. In those cases, the adapter retrieves the data sequentially and passes it to the server for screening.

IMS Access Method Restrictions

Some IMS access methods are limited in their ability to apply certain screening conditions. These restrictions can affect request optimization. The following considerations apply to specific access methods:

- Since HDAM data sources are stored randomly and accessed directly, IMS cannot retrieve their records in root key sequence. Therefore, with an HDAM data source, the adapter can only optimize equality conditions on the root key:

  KEY=*value*

  You can build a secondary index on the root key and use it to optimize sequential processing.

  Note: The NE condition is not optimized.

- With HIDAM data sources, the adapter optimizes LIKE tests with a mask by translating the LIKE into a range condition. For an example, see *Partial Key and Multi-Segment Requests in IMS* on page 1067.
- To take advantage of efficiencies available by limiting processing to one area of a Fast Path DEDB data source, the PSB must limit access to that area.

IMS Rules for Constructing SSAs From WHERE Tests

In order for the adapter to translate an SQL WHERE test into a qualified SSA:

- The field tested must be an IMS key field, search field, or a secondary index.
- The test relation must be one of the relations described in these topics.
- The tested field cannot be a floating point numeric or zoned field.

  Note: In order for the adapter to optimize selection tests on zoned key fields, you must describe the USAGE format of these fields as alphanumeric or packed in the Master File.
- The ACTUAL and USAGE formats of the tested field must be basically the same, so no format conversion is required. For example, extending with leading zeros or padding with trailing blanks is not a format conversion, but shifting the implied decimal point in a packed field is a format conversion.
- In an HDAM data source, the tests must use the equality (=) relation on the root key, with no value masking.

The following test relations can be translated to qualified SSAs:

- A comparison of a field to a list of values:

  ```
  fld relation value1 OR fld relation value2 ... OR fld relation valuen
  ```

  For a discussion of SSA generation when comparing a field to a list of values, see *Complex Screening Conditions in IMS* on page 1062.
- = <> < > <= >=
- IN
- NOT IN
- LIKE
- NOT LIKE

- BETWEEN

  The BETWEEN relation is treated as a pair of relations. For example:

  ```
  WHERE field GE . . . AND WHERE field LE . . .
  ```

  A search on a partial key (the high-order portion of a key) is also translated to a range condition and optimized.

- NOT BETWEEN

- Using WebFOCUS, INCLUDES and EXCLUDES on target segments in secondary index databases. For information, see *Qualifying Parent Segments Using INCLUDES and EXCLUDES* on page 1059.

Qualifying Parent Segments Using INCLUDES and EXCLUDES

Using WebFOCUS, you can test whether instances of a given field in a child segment include or exclude all literals in a list using the INCLUDES and EXCLUDES operators. You can also have additional screening conditions for any descendant of the INCLUDES/EXCLUDES parent segment.

Syntax: How to Qualify Parent Segments Using INCLUDES and EXCLUDES

You can connect the literals you are testing for with ANDs and ORs, however, you cannot create compound INCLUDES and EXCLUDES tests with logical AND and OR operators. The Adapter for IMS will always connect all literals used in an INCLUDES/EXCLUDES phrase with the AND condition regardless of the logical predicate used in the request.

A request that contains either of the following phrases returns stock records with cycle number instances for both 00003333 and 00001111:

```
WHERE CYCLNUMB INCLUDES 00003333 OR 00001111
```

or

```
WHERE CYCLNUMB INCLUDES 00003333 AND 00001111
```

For a record to be selected, its cycle number field must have values of both 00003333 and 00001111. If either one is missing, the record will not be selected for the report.

With the following selection criteria, every record that is not associated with the provided secondary index value is selected for the report.

```
WHERE CYCLNUMB EXCLUDES 00003333
```

An EXCLUDE request potentially results in erroneous report output if there is more than one secondary index value associated with the particular target record.

Reference: Usage Notes for INCLUDES and EXCLUDES

- INCLUDES and EXCLUDES are applicable only to the target segments in secondary index databases.
- INCLUDES and EXCLUDES cannot be used when a child segment has type U.
- Literals containing embedded blanks must be enclosed in single quotation marks.
- To use more than one INCLUDES or EXCLUDES phrase in a request, begin each phrase on a separate line.

Example: Using INCLUDES to Qualify Parent Segments

The secondary index database was created based on the IMS IVP sample database Parts.

The Stock Status record was indexed by the CYCLNUMB field in the Cycle Count record, which resulted in the following structural view of the new database:

```

```

The following request selects part keys and stock keys for all details that have requested cycle numbers.

```
TABLE FILE DIX1DBD
PRINT CYCLNUMB BY STOCKEY BY PARTKEY BY CYCLKEY
WHERE CYCLNUMB INCLUDES 00003333 AND 00001111
END
```

The output is:

```
STOCKEY     PARTKEY          CYCLKEY    CYCLNUMB
-------     -------          -------    --------
0025906026  02N51P3003F000   20         00003600
                             21         00001111
                             22         00002222
                             23         00003333
0028009126  02RC07GF273J     20         00000190
                             21         00001111
                             23         00003333
```

The report output contains extra CYCCOUNT records that are children of the selected STOCKEY record. To eliminate the extra child records, the request needs an extra screening condition to select only those CYLCNUMB fields that match one of the values in the INCLUDE condition:

```
IF CYCLNUMB EQ 00003333 OR 00001111
```

With this extra condition, the output is:

```
STOCKEY     PARTKEY          CYCLKEY    CYCLNUMB
-------     -------          -------    --------
0025906026  02N51P3003F000   21         00001111
                             23         00003333
0028009126  02RC07GF273J     21         00001111
                             23         00003333
```

Complex Screening Conditions in IMS

The general form for a complex screening condition is:

field1 relation1 value1 OR *field2 relation2 value2* OR ...

If the fields are search or sequence fields, the adapter can optimize the screening test subject to certain conditions. The adapter either constructs a single SSA or multiple SSAs, depending on the characteristics of the segment and the type of relation used.

Note: Specifying the AND operator between logical conditions in a selection test is equivalent to using multiple WHERE statements without the AND. The adapter constructs a qualified SSA that incorporates the AND operation in either case.

The following topics describe:

- The SSA buffer, and how the adapter processes SSAs that are too long to fit into the buffer.
- Conditions under which the adapter constructs a single SSA.
- Conditions under which the adapter constructs multiple SSAs.

Reference: The IMS SSA Buffer

Once the adapter constructs an SSA, it must place the SSA in the SSA buffer in order to submit it in a DL/I call. If the SSA is too long to fit into the buffer, the adapter makes the following choices between the individual screening conditions within the SSA:

- Tests on key fields have priority over all other tests.
- The remaining tests are given priority based on their order in the query statement. Since earlier tests are retained and later tests are eliminated from the SSA, you can control the SSA generation process by carefully constructing your screening conditions.

When an SSA does not fit into the SSA buffer, no error is generated. The selection tests that do not get passed to IMS in the SSA are still applied, but they are not optimized. That is, the server applies them, not IMS.

Note: The number of conditions that fit into the SSA buffer is not fixed. It varies depending on the lengths of the values in the comparisons.

Example: Constructing a Single SSA in IMS

The adapter constructs a single SSA that incorporates the entire complex logical condition if either:

- The segment has no key.
- There is a key, but it is not qualified.
- There is a qualified key, and the relation in the test on the key is the equality (=) relation or a single range.

If the entire SSA fits into the SSA buffer, it is submitted in the DL/I call. If the SSA is too long to fit into the SSA buffer, the adapter makes the choices described in *The IMS SSA Buffer* on page 1063.

The following example illustrates SSA generation when there is no equality test on the key field, but there are tests on a search field:

```
SQL
SELECT LAST_NAME, FIRST_NAME, SEQFIELD, SALARY, SSN
FROM PATDB01
WHERE SEQFIELD IN ('100000','100005') AND
      LAST_NAME IN ('BORRERO','JONES');
END
```

The trace produced is illustrated below. Note that because the sequentially ordered secondary index database is used in the search, the SQL IN condition for SEQFIELD is translated to a range test in the SSA. If the HDAM database itself had been used, the IN condition would have been translated to an equality test in the SSA:

```

14.25.42 DU FFFFFFFF FFFF5D40                        *......)         *
```

If this SSA did not fit into the SSA buffer, the adapter would retain as much of it as possible in a qualified call, after which the server would apply the remaining tests to the returned segments.

The output is:

```
LAST_NAME  FIRST_NAME  SEQFIELD  SALARY   SSN

JONES      CORNELIUS   100005    1005.00  197548684
```

Syntax: How to Construct Multiple SSAs in IMS

This topic describes how the adapter handles SSA generation when the condition in the SQL request compares a key field to a list of values. The key can be unique or non-unique. The form of such a condition is

```
WHERE key IN (value1, value2, ... ,valuen)
```

where:

key

Is a key field.

value1,...,valuen

Are the comparison values.

In this case, the adapter constructs a separate SSA for each value in the list (in ascending sort sequence) and transmits each one in turn to IMS:

```
(key EQ value1)
  .
  .
  .
(key EQ valuen)
```

The adapter first issues a DL/I call containing only the first SSA. If IMS locates a segment that satisfies the condition in the SSA, the adapter returns the segment to the server. Otherwise, the adapter issues a DL/I call that incorporates only the second SSA. It continues until IMS either locates a segment that satisfies one of the SSAs or exhausts the list of values.

Example: Constructing Multiple SSAs in IMS

In the following example, the adapter constructs three SSAs:

```
SQL
SELECT SSN, SEQFIELD, LAST_NAME
FROM PATDB01
WHERE SSN IN ('197548682', '197548685', '197548691')
END
```

The trace results show the three separate SSAs:

```
14.54.29 DU  set up SSA-Q:
14.54.29 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
14.54.29 DU 4040407E 40F1F9F7 F5F4F8F6 F8F25D40      *   = 197548682) *

14.54.29 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
14.54.29 DU 4040407E 40F1F9F7 F5F4F8F6 F8F55D40      *   = 197548685) *

14.54.29 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
14.54.29 DU 4040407E 40F1F9F7 F5F4F8F6 F9F15D40      *   = 197548691) *
```

The output is:

```
SSN        SEQFIELD  LAST_NAME

197548682  100003    SALEH
197548685  100006    JACA
197548691  100012    BOYCE
```

The next request illustrates an equality test on the key field and an additional test on a search field:

```
SQL
SELECT SSN, SEQFIELD, LAST_NAME
FROM PATDB01
WHERE SSN IN ('197548682', '197548685', '197548691') AND SEQFIELD <
'100012';
END
```

The corresponding trace shows the multiple SSAs that are generated:

```
15.14.05 DU  set up SSA-Q:
15.14.05 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
15.14.05 DU 4040407E 40F1F9F7 F5F4F8F6 F8F25CE2      *   = 197548682*S*
15.14.05 DU C5D8C6C9 C5D3C44C 40F1F0F0 F0F1F25D      *EQFIELD< 100012)*
15.14.05 DU 40                                       *                *

15.14.05 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
15.14.05 DU 4040407E 40F1F9F7 F5F4F8F6 F8F55CE2      *   = 197548685*S*
15.14.05 DU C5D8C6C9 C5D3C44C 40F1F0F0 F0F1F25D      *EQFIELD< 100012)*
15.14.05 DU 40                                       *                *

15.14.05 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
15.14.05 DU 4040407E 40F1F9F7 F5F4F8F6 F9F15CE2      *   = 197548691*S*
15.14.05 DU C5D8C6C9 C5D3C44C 40F1F0F0 F0F1F25D      *EQFIELD< 100012)*
```

The adapter constructs three SSAs and applies them one at a time:

```
(SSN EQ 197548682 AND SEQFIELD LT 100012)
(SSN EQ 197548685 AND SEQFIELD LT 100012)
(SSN EQ 197548691 AND SEQFIELD LT 100012)
```

The output is:

```
SSN        SEQFIELD  LAST_NAME

197548682  100003    SALEH
197548685  100006    JACA
```

If the SSA generated by combining the conditions in all the WHERE statements is too long to fit into the SSA buffer, the adapter retains as much of it as possible in a qualified call by applying the rules described in *The IMS SSA Buffer* on page 1063.

Reference: Sequentially Accessed Root Segments in IMS

If the root segment is the target of the SSA generated by a request, and if it has a unique key, the adapter assumes that IMS will use an index or randomizing scheme to locate the segment without an exhaustive search of the root segment chain. Therefore, the adapter retrieves the segment with qualified GET UNIQUE calls.

Even if the assumption that there is an index or randomizing scheme for IMS to use is not valid, as with HSAM data sources, each call starts its search at the first record in the data source. In this case, it is preferable to describe the root segment as having no key (SEGTYPE=S0), and not to describe any field's alias with the KEY suffix. This causes the adapter to issue qualified GET NEXT calls that access the roots sequentially and maintain the current data source position from one call to the next.

Partial Key and Multi-Segment Requests in IMS

The following topics illustrate SSAs for requests that select on a partial key and requests that access values from multiple segments.

Syntax: How to Optimize Selections on a Partial Key in IMS

Record selection on a partial key can be optimized as a range condition using GE and LE unless the data source is an HDAM data source. The partial key must be the high-order (leftmost) portion of the key. To search on a partial key, use a mask as the comparison value in the relation.

```
WHERE field LIKE 'xxx%'
```

where:

xxx

Are any number of characters that constitute the leftmost portion of the key.

%

Is a wildcard character indicating that any string of characters in this position and beyond satisfies the screening criteria.

Example: Optimizing Selections on a Partial Key in IMS

The adapter translates the LIKE condition in the following request to a range using GE and LE:

```
SQL
SELECT SSN, SEQFIELD, LAST_NAME
FROM PATDB01
WHERE SSN LIKE '1975486%';
END
```

The trace results show that the selection test is translated to a range condition:

```
DU ssa 1
10.09.21 DU D7C1E3C9 D5C6D640 5C604DE2 E2D54040      *PATINFO *-(SSN  *
10.09.21 DU 4040406E 7EF1F9F7 F5F4F8F6 00005CE2      *   >=1975486..*S*
10.09.21 DU E2D54040 4040404C 7EF1F9F7 F5F4F8F6      *SN     <=1975486*
10.09.21 DU FFFF5D40                                 *..)             *
```

To define the range of values, the adapter appends the lowest hexadecimal value (00) and the highest hexadecimal value (FF) to 1975486 (00 and FF are not alphanumeric representations of numbers; therefore they do not print as such on the right side of the dump).

The output is:

```
SSN        SEQFIELD  LAST_NAME

197548679  100000    ROSANO
197548680  100001    LOVELACE
197548681  100002    BORRERO
197548682  100003    SALEH
197548683  100004    SALGADO
197548684  100005    JONES
197548685  100006    JACA
197548686  100007    PENA
197548687  100008    FREEMAN
```

Example: Generating Multi-Segment Requests in IMS

When a request requires access to multiple segments, the adapter constructs one SSA for each segment. If the selection criteria for a particular segment can be optimized, its corresponding SSA is qualified.

The following request includes an equality test on PARTKEY, the root key of the DI21PART data source, but it contains no selection criteria for the STANKEY field in the STANINFO segment:

```
SQL
SELECT PARTKEY, STANKEY
FROM DI21PART
WHERE PARTKEY = '02AN960C10'
END
```

The SSA for the root segment, PARTROOT, is qualified, but the SSA for the STANINFO segment is not qualified:

```
10.53.47 DU  set up SSA-Q:
10.53.47 DU D7C1D9E3 D9D6D6E3 5C604DD7 C1D9E3D2      *PARTROOT*-(PARTK*
10.53.47 DU C5E8407E 40F0F2C1 D5F9F6F0 C3F1F040      *EY = 02AN960C10 *
10.53.47 DU 40404040 40405D40                        *      )         *

10.53.47 DU E2E3C1D5 C9D5C6D6 5C604040               *STANINFO*-      *
```

The output is:

```
PARTKEY     STANKEY

02AN960C10  02
```

Auto Index Selection

When the Access File defines secondary indexes for a data source, the adapter analyzes each request to determine the most efficient entry point into the data source.

The adapter scans each request to determine whether fields used in record selection tests are key fields, secondary indexes, or the high-order (leftmost) parts of either. Depending on the request criteria, the adapter selects the appropriate PCB for the most efficient access to the data.

Example: Using Auto Index Selection

The PATIENT data source has a secondary index named IXADMD on the ADMIT_DATE field.

In the following request, the field referenced in the WHERE condition is the field associated with the secondary index called IXADMD:

```
SQL
SELECT LAST_NAME,SALARY,ADMIT_DATE
  FROM PATINFO
WHERE ADMIT_DATE = '19920925'
END
```

The trace shows that the adapter generates a qualified SSA using the IXADMD index:

```
11.44.55 DU D7C1E3C9 D5C6D640 5C604DC9 E7C1C4D4      *PATINFO *-(IXADM*
11.44.55 DU C440407E 40F1F9F9 F2F0F9F2 F55D40        *D  = 19920925)  *
```

The output is:

```
LAST_NAME  SALARY   ADMIT_DATE

CAPPARELLI 1024.00  19920925
CAPPARELLI 16682.00 19920925
```

Reference: Selection Tests on Multiple Fields or a Field With Multiple Indexes

If a request includes record selection tests on more than one field, or if a field participates in more than one type of index, the adapter uses the following order of precedence in choosing the PCB to use:

1. .KEY field (primary index).

   If a field in a record selection test is both a .KEY field and the high-order portion of a secondary index, the adapter accesses the data source using the primary index on the .KEY field.

However, if the data source is an HDAM database, and if the request includes a range test on a field that is both an .HKY field and a secondary index field, the adapter accesses the data source through the secondary index field.

2. Secondary index field.
3. .IMS field (search field).

Example: Using Auto Index Selection to Generate a Qualified SSA

The following example demonstrates how secondary indexes and the Auto Index Selection feature affect SSA generation.

The following Master File, AIHDAM, describes an HDAM database. Without a secondary index, the adapter would generate an unqualified SSA on the key field. However, a secondary index is described in the Access File:

```
FILE=AIHDAM   ,SUFFIX=IMS   ,$
SEGNAME=LANGUAGE ,SEGTYPE=S0 ,$
 FIELD=EMPLOYEE_ID6  ,ALIAS=EMPL6.HKY   ,I9 ,I4  ,$
 FIELD=LANGUAGE      ,ALIAS=LANG6.IMS   ,A15 ,A15 ,$
```

The adapter can use the Auto Index Selection feature on the following request to generate a qualified SSA for the range test on the key field:

```
SELECT *
FROM AIHDAM
WHERE EMPLOYEE_ID6 BETWEEN 5248 AND 6393
```

```
14.46.43 DU  set up SSA-Q:
14.46.43 DU D3C1D5C7 E4C1C7C5 5C604DC9 E7C5D4D7      *LANGUAGE*-(IXEMP*
14.46.43 DU F640406E 7E000014 805CC9E7 C5D4D7F6      *6  >=....*IXEMP6*
14.46.43 DU 40404C7E 000018F9 5D40                   *  <=...9)       *
```

Maintaining IMS Data Sources

The Adapter for IMS supports SQL update commands to IMS data sources without the use of remote procedures. For example, UPDATE, INSERT, and DELETE will be translated into equivalent IMS DL/1 calls.

General Guidelines for Maintaining IMS Data Sources

The Structured Query Language (SQL) is intended to be used for access to relational tables, while IMS databases are hierarchical structures. The Adapter for IMS is designed to balance both, so that IMS data structures are treated as if they were relational tables. As this is not always possible, certain rules must be followed.

The adapter is designed to work against a single IMS segment in one path of the IMS database as the target of the SQL Data Manipulation Language (DML) statement. SQL set orientated behavior (multiple updates with one SQL statement) is not supported.

The WHERE clause of the SQL statement must contain all the key fields in the path to the target segment. If a segment does not have a key, at least one field from that segment must be specified in the WHERE clause. Any segment referenced in the SQL query must, using the WHERE clause, be a unique occurrence of that segment. For segments with unique keys, this is guaranteed by IMS, but for segments that have non-unique or no keys, additional fields must be specified in the WHERE clause to uniquely identify the segment. If additional fields are included in the WHERE clause for any segment, including uniquely keyed segments, they will be used in conjunction with the key, to qualify the segment.

Syntax: How to Issue SQL INSERT in IMS

```
INSERT INTO mfdname [(field1, field2 ...)] VALUES (value1, value2 ...)
```

General Rules

The following rules apply to SQL INSERT syntax:

- If you do not specify the field name list, the value list must contain values for all fields in all segments in the Master File as long as the Master File only specifies a single path IMS file.
- If the Master File is multi-path, the field name list must be included and only be for a single path.
- If you specify the field name list, the value list only needs to specify, in field name list order, the field names supplied. As a minimum, you must supply all the key fields for all the segments in the path to the target.
- If a segment is not present, default values will be generated for all non-key fields not supplied, and the missing path segment(s) will be inserted along with the target segment.

Unique Keyed Segment

For a segment with a unique key, the keyfield value is used to insert the target segment. If any additional *fieldname=value* pairs are supplied for a segment in the path, they are used to qualify that path segment.

Any fields not supplied for the target default to type.

Non-unique Keyed Segment

- For a segment with a non-unique key in the target segment or in the path to the target, the segment will be inserted, within keyfield range, according to the RULES=(,FIRST) or RULES=(,LAST) setting for the segment. All segment occurrences of this type whether in the path or target, will be checked for uniqueness, within keyfield range, using the values list.
- If a non-unique segment that is a match is found before the end of the keyfield range, the transaction will be rejected.
- If only the keyfield of the target is supplied, this must be the first segment in the keyfield range, otherwise the transaction will be rejected. No positioning calls will be made. Therefore, RULES=(,HERE) will not be honored. IMS will default to RULES=(,FIRST) for the keyfield value in this situation.

Non-keyed Segment

- A segment with no key or target, or a segment in the path, will be inserted according to the RULES=(,FIRST) or RULES=(,LAST) setting. All segment occurrences of this type, whether in the path or target, will be checked for uniqueness using the values list.
- If a segment is found not to be unique, that is no match is found before the end of the twin chain, the transaction will be rejected. No positioning calls will be made. Therefore, RULES=(,HERE) will not be honored. IMS will default to RULES=(,FIRST) in this situation.

Syntax: How to Issue SQL DELETE in IMS

```
DELETE FROM mfdname WHERE fieldname=value [ AND fieldname=value ... ]
```

General Rules

The following rules apply to SQL DELETE syntax:

- As a minimum, you must supply all the key fields for all the segments in the path to the target. Only one target segment will be deleted. IMS will cascade the delete to dependent segments.
- Additional *fieldname=value* pairs may be included for the target segment and any segment in the path that has no key or a non-unique key. It is recommended to use IMS search fields for any additional *fieldname=value* pairs.

Unique Keyed Segments

For a segment with a unique key, the keyfield value is used to delete the target segment. If you supply any additional *fieldname=value* pairs, they will be used to qualify the deletion.

Non-unique Keyed Segments

For a segment with a non-unique key, you must supply the keyfield. If the WHERE condition(s) for this type of segment, in the path or target, do not identify a unique occurrence, the transaction will be rejected.

Non-keyed Segments

For a segment with no key, you must supply at least one *fieldname=value* pair. If the WHERE condition(s) for this type of segment, in the path or target, do not identify a unique occurrence, the transaction will be rejected. The use of any IMS search fields for this type of segment is highly recommended for efficiency.

Syntax: How to Issue SQL UPDATE in IMS

```
UPDATE mfdname  SET fieldname=value [SET fieldname=value...]
WHERE fieldname=value
[AND fieldname=value]
```

General Rules

The following rules apply to SQL UPDATE syntax:

- As a minimum, in the WHERE condition, you must supply all the key fields for all the segments in the path to the target. Only one target segment will be updated.
- You may include additional *fieldname=value* pairs for the target or any segment in the path. When additional *fieldname=value* pairs are present for the target segment, these will be used for change verification protocol processing. If all target *fieldname=value* pairs that are present match the IMS segment field values, the segment will be updated with the SET *fieldname* values.

Unique Keyed Segments

For a segment with a unique key, the keyfield value and any additional *fieldname=value* pairs are used to qualify the target segment for update.

Non-unique Keyed Segments

For a segment with a non-unique key, you must supply the keyfield. If the WHERE condition(s) for this type of segment do not identify a unique occurrence, the transaction will be rejected. If the set values would result in the updated segment matching an existing segment, the transaction will be rejected.

Non-keyed Segments

For a segment with no key, you must supply at least one *fieldname=value* pair. If the WHERE condition(s) for this type of segment do not identify a unique occurrence, the transaction will be rejected. The use of any IMS search fields for this type of segment is highly recommended for efficiency. If the set values would result in the updated segment matching an existing segment, the transaction will be rejected.

Syntax: How to Obtain the Number of Records Affected by an SQL INSERT, UPDATE, or DELETE Command

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the right-click menu. The Change Settings pane opens.

```
*ENGINE* INT SET PASSRECS {ON|OFF}
```

where:

`INT`

Indicates that the PASSRECS setting in this command will be applied globally to all adapters that support SQL INSERT, UPDATE, and DELETE commands.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

In addition, the adapter updates the &RECORDS system variable with the number of rows affected. You can access this variable using Dialogue Manager.

Reference: Processing Not Supported for Maintaining IMS Data Sources

The following processing is not supported:

- Null data values.

- Embedded SELECT within INSERT.
- Cursor control, for example, WHERE CURRENT OF on UPDATE or DELETE processing.
- Positioning for RULES=(,HERE) on the SEGM statement for INSERT.
- SQL DML statements using IMS secondary indices.

Commit and Rollback Processing in IMS

IMS data sources can participate in transactions with other types of data sources. These transactions can be coordinated automatically by the XA Transaction Management feature or can be controlled by the user application program.

Commit and Rollback Processing Without XA Transaction Management

When the Adapter for IMS is used for any modification action, it automatically issues a COMMIT after each INSERT, UPDATE, or DELETE call. If the IMS segment processing is part of a logical unit of work (LUW) that involves any relational data sources, the relational transactions should not be committed until the single IMS process has completed successfully. No user rollback of the IMS process is supported. If the IMS process fails, a ROLLBACK is issued by the adapter, and the user application must issue a ROLLBACK of the relational transactions that are part of the LUW.

Commit and Rollback Processing With XA Transaction Management

Although IMS data sources are non-XA compliant, an IMS data source can participate in a two-phase commit handled by the Transaction Coordinator component of the XA Transaction Management feature if:

- The IMS data source is the last participant.
- The IMS data source is the only non- XA compliant participant.

For related information, see *XA Transaction Management* on page 2689.

Metadata Considerations for Maintaining IMS Data Sources

No changes to the Master File are required for maintaining IMS data sources.

Syntax: How to Enable Write Access for IMS

To enable Write access for an IMS data source, specify the WRITE=YES attribute in the Access File.

```
PSB=psbname, WRITE={YES|NO}
```

where:

psbname

Is the name of the FOCPSB library member to use. This name must be identical to the name of the actual PSB that IMS will access. If the member does not exist, the following message is generated:

```
(EDA4261) FOCPSB MEMBER NOT FOUND: psbname
```

YES

Allows SQL update for this database.

NO

Does not allow SQL update for this database. This value is the default.

Reference: Sample IMS Master File for Maintenance Examples

The following database and segment values will be used in all examples.

```
FILENAME=IMSUPDDB,SUFFIX=IMS,$
$
$SEGA has a unique KEY
SEGNAME=SEGA,SEGTYPE=S0,$
  FIELDNAME=FA1    ,ALIAS=FA1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FA2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FA3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
$
$SEGB has a unique KEY
SEGNAME=SEGB,SEGTYPE=S0,PARENT=SEGA,$
  FIELDNAME=FB1    ,ALIAS=FB1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FB2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FB3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
$
$SEGC has a unique KEY
SEGNAME=SEGC,SEGTYPE=S0,PARENT=SEGA,$
  FIELDNAME=FC1    ,ALIAS=FC1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FC2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FC3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
$
$SEGD has a non-unique KEY
SEGNAME=SEGD,SEGTYPE=S0,PARENT=SEGC,$
  FIELDNAME=FD1    ,ALIAS=FD1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FD2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FD3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$

SEGNAME=SEGB,SEGTYPE=S0,PARENT=SEGA,$
  FIELDNAME=FB1    ,ALIAS=FB1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FB2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FB3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
$
$SEGC has a unique KEY
```

```
SEGNAME=SEGC,SEGTYPE=S0,PARENT=SEGA,$
  FIELDNAME=FC1    ,ALIAS=FC1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FC2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FC3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
$
$SEGD has a non-unique KEY

SEGNAME=SEGD,SEGTYPE=S0,PARENT=SEGC,$
  FIELDNAME=FD1    ,ALIAS=FD1KEY.KEY    ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FD2    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
  FIELDNAME=FD3    ,ALIAS=              ,FORMAT=A5,ACTUAL=A5,$
```

Example: Inserting a Root Segment in IMS

The IMS database has one record. The following INSERT statement inserts a second root segment:

```
INSERT INTO IMSUPDDB (FA1,FA2,FA3) VALUES('A2','AAAAA','BBBBB')
```

Example: Inserting a Child Segment in IMS

The following INSERT statement inserts a new SEGB segment:

```
INSERT INTO IMSUPDDB (FA1,FB1,FB2,FB3)
VALUES('A2','A2B1','AAAAA','DDDDD')
```

Example: Inserting Three Segments Under a Root Segment in IMS

The following INSERT statements insert three SEGD segments for root A1.

```
INSERT INTO IMSUPDDB (FA1,FC1,FD1,FD2,FD3)
   VALUES('A1','A1C1','C1D1','D1111','D1111')

INSERT INTO IMSUPDDB (FA1,FC1,FD1,FD2,FD3)
   VALUES('A1','A1C1','C1D1','D2222','D2222')

INSERT INTO IMSUPDDB (FA1,FC1,FD1,FD2,FD3)
   VALUES('A1','A1C1','C1D2','D1111','D1111')
```

Example: Inserting Two Segments on a Single Path of the Data Source in IMS

The following INSERT statement inserts a new SEGC as well as a new SEGD. Default values of blanks or zeros will be used for SEGC for any column not in the values list.

```
INSERT INTO IMSUPDDB (FA1,FC1,FD1,FD2,FD3)
   VALUES('A1','A1C2','C2D2','D2111','D2111')
```

Example: Deleting a Root and Dependent Segments in IMS

The following DELETE statement deletes the root segment A2 and all dependents.

```
DELETE FROM IMSUPDDB WHERE FA1 = 'A2'
```

Chapter 39

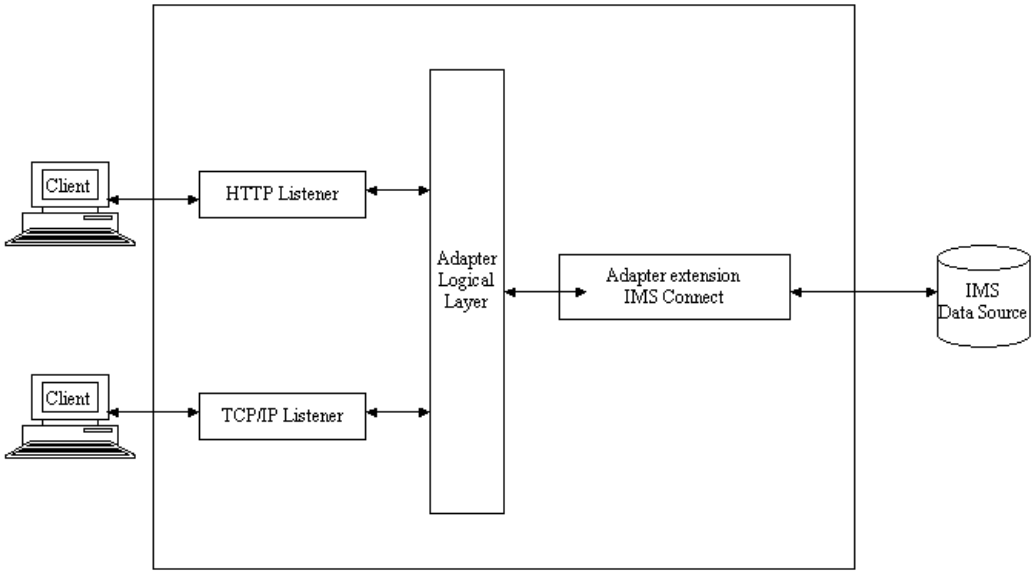
Using the Adapter for IMS Transactions

The Adapter for IMS Transactions processes input parameters, creates and sends requests to the IMS Transactions Server, and creates an answer set based on the received response.

In this chapter:

Preparing the IMS Transactions Environment

The following diagram illustrates the basic flow of the Adapter for IMS Transactions:



This diagram illustrates how the client application communicates with the Application Adapter Server using the TCP/IP or HTTP protocol. The communication to the IMS region uses IMS Connect.

To provide for transparent execution of IMS transactions, metadata describing the program input and output areas is held on the server. This metadata can be derived from COBOL copy book entries, if available.

A Web Console is available as the primary configuration and maintenance tool. It is used to add or change adapter communication parameters and in creating or maintaining the metadata associated with the programs to be executed.

IMS Transactions Adapter Supported Platforms and Release Information

The following platforms are supported:

- Microsoft Windows using IMS Connect/OTMA (any IBM supported version).
- UNIX using IMS Connect/OTMA (any IBM supported version).
- z/OS using OTMA.

Note:

- IBM IMS Connect provides high-performance communications for IMS between one or more TCP/IP or local/390 clients and one or more IMS systems.
- IMS(TM) Open Transaction Manager Access (OTMA) is a transaction-based, connectionless client/server protocol. Though easily generalized, its implementation is specific to IMS in an MVS(TM) sysplex environment. The domain of the protocol is restricted to the domain of the MVS Cross-System Coupling Facility (XCF).
- OTMA addresses the problem of connecting a client to a server so that the client can support a large network, or a large number of sessions, while maintaining high performance.

Configuring the Adapter for IMS Transactions

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to IMS Transactions, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one data source by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to IMS Transactions takes place when the first query that references that connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

For detailed instructions about declaring connection attributes for your operating system, see *Configuring the Adapter on Windows and UNIX* on page 1082 or *Configuring the Adapter on z/OS* on page 1086.

Configuring the Adapter on Windows and UNIX

The Adapter for IMS Transactions must be configured in order to gain access to IMS programs, create metadata and build the repository. The HWS command *viewers* can provide some of the information required for configuration. The setup information becomes the content of the Adapter for IMS Transactions communications nodes.

To configure the Application Adapter Server for IMS access, perform these steps:

1. Configure the Adapter for TCP/IP on Windows or UNIX.
2. Create Synonyms.

Before you begin this configuration process, you must start the Web Console.

Procedure: How to Configure the Adapter on Windows and UNIX

You can configure the adapter from the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for IMS Transactions on Windows and UNIX

The IMS Transaction adapter is under the *Procedures* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

CONNECTION NAME

1-8 character logical name. Select a name that reflects the IMS region you are configuring the connection for.

HOST

DNS name of the host LPAR of the target IMS region. You can also code the four part IP address.

PORT

Port number on which the IMS Connect is listening. This value may be obtained from viewhws. See *Output From Viewhws* on page 1085.

DATASTORE

ID of the IMS region that provides the transaction processing. This value may be obtained from viewhws. See *Output From Viewhws* on page 1085.

RACF GROUP

RACF Group for the user (when OTMA security is not none.)

SECURITY

There are two methods by which a user can be authenticated when connecting to an IMS Application:

- **Explicit.** If you require all connected users to connect to IMS using the same security profile, select *Explicit* and provide a User ID and Password.
- **Password Passthru.** If Password Passthru is selected, the user ID and password sent from the client application will be used to connect to IMS.

If Explicit security is selected, two additional input fields are shown for User and Password. Enter values that are valid for logging on to IMS.

For more information about available security models, see *Security on Microsoft Windows and UNIX* on page 1085.

User

A user ID that is valid for an IMS logon.

Password

The password associated with the user ID above.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually on Windows and UNIX

```
ENGINE IMSTRAN SET CONNECTION_ATTRIBUTES connection /,: "HOST dns_name
 COM PORT port DATASTORE IMS_region RACFGROUP RACF_Group"
```

where:

`IMSTRAN`

Indicates the adapter.

`connection`

1-8 character logical name. Select a name that reflects the IMS region you are configuring the connection for.

`dns_name`

DNS name of the host LPAR of the target IMS region. You can also code the four part IP address.

`port`

Port number on which the IMS Connect is listening. This value may be obtained from viewhws.

IMS_region

ID of the IMS region that provides the transaction processing. This value may be obtained from viewhws.

RACF_Group

RACF Group for the user.

For information about security options, see *Security on Microsoft Windows and UNIX* on page 1085.

Example: Declaring Connection Attributes

```
ENGINE IMSTRAN SET CONNECTION_ATTRIBUTES IMS8C /,: "HOST IBIMVS.IBI.COM
 PORT 6686 DATASTORE IMS8C RACFGROUP EDA"
```

Example: Output From Viewhws

```
IEE600I        REPLY TO 01 IS;VIEWHWS
HWSC0001I      HWS ID=HWSB Racf=N
HWSC0001I      Maxsoc=2000 Timeout=8888 23
HWSC0000I      *IMS CONNECT READY* HWSB
HWSC0001I      Datastore=IMS7B Status=ACTIVE
HWSC0001I          Group=IMSGRP7B Memb
HWSC0001I      Datastore=IMS6A Status=ACTIVE
HWSC0001I          Group=IMSGRP6A Member=HWSMEM6A
HWSC0001I          Target Member=TMEM6A
HWSC0001I      Datastore=IMS7A Status=NOT ACTIVE
HWSC0001I          Group=IMSGRP7A Member=HWSMEM7A
HWSC0001I          Target Member=TMEM7A
HWSC0001I          Port=6685 Status=ACTIVE
HWSC0001I          No active Clients
```

Reference: Security on Microsoft Windows and UNIX

If the adapter is deployed on Microsoft Windows or UNIX, starting the server without security is recommended. The client application should provide the User ID and Password to be used for the connection to IMS. This User ID and Password is passed through to IMS for validation. The server does not validate the User ID and Password with the operating system.

If the Explicit option is selected and security information is entered in the adapter configuration window, it overrides this security mode and a single User ID and Password are used for all connected users.

If the adapter is started with security, and Password Passthru is selected, the local security profiles must be synchronized with those of the IMS platform, thereby creating additional security maintenance overhead.

Configuring the Adapter on z/OS

Configuring the adapter consists of specifying connection and authentication information for each connection on z/OS.

Procedure: How to Configure the Adapter on z/OS

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for IMS Transactions on z/OS

The IMS Transaction adapter is under the *Procedures* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

CONNECTION NAME

1-8 character logical name. Select a name that reflects the IMS region you are configuring the connection for.

XCF Member

Target member name. This value may be obtained from /DIS OTMA. See *Output From /DIS OTMA* on page 1088.

XCF Member Group

Target member group name. This value may be obtained from /DIS OTMA. See *Output From /DIS OTMA* on page 1088.

XCF User ID

User ID.

RACF Group

RACF group.

SECURITY

There are two methods by which a user can be authenticated when connecting to an IMS Application:

- **Explicit.** If you require all connected users to connect to IMS using the same security profile, select *Explicit* and provide a User ID and Password.
- **Password Passthru.** If Password Passthru is selected, the user ID and password sent from the client application will be used to connect to IMS.

If Explicit security is selected, two additional input fields are shown for User and Password. Enter values that are valid for logging on to IMS.

For more information about available security models, see *Security on z/OS* on page 1089.

User

Is a user ID that is valid for an IMS logon.

Password

Is the password associated with the user ID above.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Example: Output From /DIS OTMA

```
R 20,/DIS OTMA
IEE600I REPLY TO 20 IS;/DIS OTMA
DFS000I     GROUP/MEMBER      XCF-STATUS   USER-STATUS    SECURITY
IM8C
DFS000I     IMSGRP8C
IM8C
DFS000I     -TMEM8C           ACTIVE       SERVER         NONE
IM8C
DFS000I     -HWSMEM8C         ACTIVE       ACCEPT TRAFFIC
IM8C
```

Syntax: How to Declare Connection Attributes Manually on z/OS

```
ENGINE IMSTRAN SET CONNECTION_ATTRIBUTES connection /,: "XCFMEMB
 target_member_name XCFGROUP target_member_group_name XCFUSMEMB userid
 RACFGROUP racf_group"
```

where:

connection

1-8 character logical name. Select a name that reflects the IMS region you are configuring the connection for.

target_member_name

Name of the target member. This value may be obtained from /DIS OTMA.

target_member_group_name

Name of the target member group. This value may be obtained from /DIS OTMA.

userid

User ID.

racf_group

RACF group.

For information about security options, see *Security on z/OS* on page 1089.

Example: Declaring Connections Attributes on z/OS

```
ENGINE IMSTRAN SET CONNECTION_ATTRIBUTES IMS8C /,: "XCFMEMB TMEM8C
  XCFGROUP IMSGRP8C XCFUSMEMB EDAERH RACFGROUP EDA"
```

Reference: Security on z/OS

If the adapter is deployed on z/OS, you must start the server with security turned on (the default).

The client application must provide a valid User ID and Password that is authenticated by the Adapter for IMS Transactions with calls to security packages (RACF, ACF2 and Top Secret). If the User ID and Password are valid, the subsequent connection to IMS is Trusted.

Managing IMS Transactions Metadata

When the server invokes a transaction or procedure, its needs to know how to build the request, what parameters to pass, and how to format an answer set from the response. For each transaction the server will execute, you must create a synonym that describes the layout of the request/response area.

Creating Synonyms

Synonyms define unique names (or aliases) for each transaction or procedure that is accessible from the server. Synonyms are useful because they hide the underlying transaction or procedure from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows the input parameters and the response layout to be moved while allowing client applications to continue functioning without modification. For example, moving a transaction or procedure from a test region to production. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.

- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for IMS Transactions on Windows and UNIX

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Collection of Cobol definitions

Directory

Enter a directory name to display all members in the directory path.

File name/File extension

If you wish to limit retrieval, you can enter a file name and/or file extension:

- In the File name box, enter a full name or a partial name with a wildcard symbol %. A full name returns just that entry. A name with a wildcard symbol may return many entries.
- In the File extension box, enter an extension with or without the wildcard symbol %.

Synonym name

Type the name of the synonym.

Program name

Type the name of the IMS Transactions program or APPC transaction.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Input Segment Definition

Is the name of the COBOL FD file that contains information about input parameters.

There can be no more than one set of input COBOL Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Output Segment Definition

Is the name of the COBOL FD file that contains information about output parameters.

There can be no more than one set of output Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Reference: Synonym Creation Parameters for IMS Transactions on z/OS

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

File System Selection

Choose one of the following options from the drop-down list:

- *Fully qualified PDS name* to indicate a partitioned dataset on MVS.

  In the input boxes provided, type a PDS name preceded by // and a Member name containing the location of the COBOL FD source. If you wish, you can filter the member name using a wildcard character (%).

  or

- *Absolute HFS directory pathname* to indicate a hierarchical file structure on USS.

  In the input boxes provided, type a Directory name to specify the HFS location that contains the COBOL FD and a File name and File extension. If you wish, you can filter the file and extension using a wildcard character (%).

- *Applications* to indicate a pre-configured HFS directory.

Synonym name

Type the name of the synonym.

Program name

Type the name of the IMS Transactions program or APPC transaction.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Customize

Optionally, select *Customize COBOL FD conversion options* to customize how the COBOL FD is translated. If you do not select the check box, default translation settings are applied.

For more information, see *Customization Options for COBOL File Descriptions* on page 2700.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Input Segment Definition

Is the name of the COBOL FD file that contains information about input parameters.

There can be no more than one set of input COBOL Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Output Segment Definition

Is the name of the COBOL FD file that contains information about output parameters.

There can be no more than one set of output Copybooks per synonym. You can choose the same Copybook or different Copybooks for input and output parameters.

Example: Master File for IMS TRAN Adapter

```
FILENAME=IMSTPART, SUFFIX=IMSTRAN , $
  SEGMENT=SEG1, SEGTYPE=S0, $
$  GROUP=PARTKEY_INPUT, USAGE=A50, ACTUAL=A50, $
    FIELDNAME=PARTKEY, USAGE=A50, ACTUAL=A50, $
  SEGMENT=SEG11, SEGTYPE=S0, PARENT=SEG1, $
$  GROUP=PARTROOT_OUTPUT, USAGE=A268, ACTUAL=A268, $
    FIELDNAME=FILLER, USAGE=A3, ACTUAL=A3, $
    FIELDNAME=RECTYPE, USAGE=A1, ACTUAL=A1, $
    FIELDNAME=FILLER, USAGE=A22, ACTUAL=A22, $
    FIELDNAME=PARTNUM, USAGE=A12, ACTUAL=A12, $
    FIELDNAME=FILLER, USAGE=A18, ACTUAL=A18, $
    FIELDNAME=DESCRIPTION, USAGE=A20, ACTUAL=A20, $
    FIELDNAME=FILLER, USAGE=A26, ACTUAL=A26, $
    FIELDNAME=PROCCODE, USAGE=A12, ACTUAL=A12, $
    FIELDNAME=FILLER, USAGE=A18, ACTUAL=A18, $
    FIELDNAME=INVCODE, USAGE=A8, ACTUAL=A8, $
    FIELDNAME=FILLER, USAGE=A26, ACTUAL=A26, $
    FIELDNAME=MAKEDEPT, USAGE=A12, ACTUAL=A12, $
    FIELDNAME=FILLER, USAGE=A18, ACTUAL=A18, $
    FIELDNAME=PREVNO, USAGE=A8, ACTUAL=A8, $
    FIELDNAME=FILLER, USAGE=A26, ACTUAL=A26, $
    FIELDNAME=MAKETIME, USAGE=A12, ACTUAL=A12, $
    FIELDNAME=FILLER, USAGE=A18, ACTUAL=A18, $
    FIELDNAME=COMMCODE, USAGE=A8, ACTUAL=A8, $
```

SEG1, the input segment, was generated from the following COBOL FD:

```
01  PARTKEY-INPUT.
           05 PARTKEY             PIC X(50).
```

SEG11, the output segment, was generated from the following COBOLFD:

```
01  PARTROOT-OUTPUT.
           05 FILLER       PIC X(3).
           05 RECTYPE      PIC X(1).
           05 FILLER       PIC X(22).
           05 PARTNUM      PIC X(12).
           05 FILLER       PIC X(18).
           05 DESCRIPTION  PIC X(20).
           05 FILLER       PIC X(26).
           05 PROCCODE     PIC X(12).
           05 FILLER       PIC X(18).
           05 INVCODE      PIC X(8).
           05 FILLER       PIC X(26).
           05 MAKEDEPT     PIC X(12).
           05 FILLER       PIC X(18).
           05 PREVNO       PIC X(8).
           05 FILLER       PIC X(26).
           05 MAKETIME     PIC X(12).
           05 FILLER       PIC X(18).
           05 COMMCODE     PIC X(8).
```

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Access File Attributes

Keyword	Description
SEGNAME	Is the name of the input segment in the Master File.
CONNECTION	Indicates the connection_name as previously specified in a SET CONNECTION_ATTRIBUTES command. Defaults to the default connection.
TRANSACTION	Is the name of transaction to be executed.

Example: Access File for Transaction/Program

```
SEGNAME=SEG1, CONNECTION=IMS8C, TRANSACTION=part, $
```

Note: Do not change the FLOAT or INTEGER parameter values.

Invoking an IMS Transaction

To invoke a IMS Transactions transaction, you issue a Data Manipulation Language (DML) request, also known as a TABLE command, an SQL SELECT statement, or an EX command. (DML is the WebFOCUS internal retrieval language.) For information about the Data Manipulation Language, see the *Stored Procedures Reference* manual.

Syntax: How to Invoke a Transaction Using TABLE

```
TABLE FILE synonym
PRINT [parameter [parameter] ... | *]
[IF in-parameter EQ value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the IMS Transactions transaction you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

IF/WHERE

Is used if you want to pass values to input parameters.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

Syntax: How to Invoke a Transaction Using SELECT

```
SQL
SELECT [parameter [parameter] ... | *] FROM synonym
[WHERE in-parameter = value]
  .
  .
  .
END
```

where:

synonym

Is the synonym of the IMS Transactions transaction you want to invoke.

parameter

Is the name of a parameter whose values you want to display. You can specify input parameters, output parameters, or input and output parameters.

If the transaction does not require parameters, enter an * in the syntax. This displays a dummy segment, created during metadata generation, to satisfy the structure of the SELECT statement.

*

Indicates that you want to display all indicated parameters.

WHERE

Is used if you want to pass values to input parameters.

You must specify the value of each parameter on a separate line.

in-parameter

Is the name of an input parameter to which you want to pass a value.

value

Is the value you are passing to an input parameter.

Syntax: How to Invoke a Transaction Using EX

```
EX [app_name_space/]syn_name  1=parm1_val,..., N=parmN_val

EX [app_name_space/]syn_name prm1_name=prm1_val,... ,
                             prmN_name=prmN_val

EX [app_name_space/]syn_name [, parm1_val [,...[, parmN_val]]]
```

where:

app_name_space

Is the apps directory name under which the synonyms are stored. This value is optional.

syn_name

Is the user friendly name of a repository entry that represents the object to be executed in the vendor environment.

parmname

Is the name of the parameter taken from the input metadata description.

1=parm1_val

N=parmN_val

prm1_name

prm1_val

parmN_val

Are the parameter values that match the input metadata description.

Example: Invoking the IMSTRAN Transaction

The following requests produce identical output:

```
TABLE FILE IMSTPART
PRINT PARTNUM DESCRIPTION PROCCODE INVCODE MAKEDEPT PREVNO MAKETIME
COMMCODE
IF PARTKEY EQ 'an960c10'
END

SQL
SELECT
PARTNUM,DESCRIPTION,PROCCODE,INVCODE,MAKEDEPT,PREVNO,MAKETIME,COMMCODE
FROM IMSTPART
WHERE PARTKEY='an960c10'
END
```

The output is:

```
PARTNUM  DESCRIPTION PROCCODE INVCODE MAKEDEPT REVNO MAKETIME COMMCODE
-------  ----------- -------- ------- -------- ----- -------- --------
AN960C10 WASHER      74       2       1        2-00  63       14
```

The following EX commands invoke the IMSTRAN transaction:

```
EX IMSTPART 'AN960C10'

EX IMSTPART PARTKEY='AN960C10'

EX IMSTPART 1='AN960C10'
```

The IMSTPART transaction returns the data associated with PARTKEY 'AN960C10':

```
FILE=SQLOUT ,SUFFIX=FIX ,$ SEGNAME=SQLOUT ,$ FIELD=FILLER , E2 ,A3 ,A3 ,
,$ FIELD=RECTYPE , E3 ,A1 ,A1 , ,$ FIELD=FILLER , E4 ,A22 ,A22 , ,$
FIELD=PARTNUM , E5 ,A12 ,A12 , ,$ FIELD=FILLER , E6 ,A18 ,A18 , ,$
FIELD=DESCRIPTION , E7 ,A20 ,A20 , ,$ FIELD=FILLER , E8 ,A26 ,A26 , ,$

```

Invoking an IMS Stored Procedure

This topic contains overview, configuration, and installation information (as applicable) for the following IMS/TM procedures:

- **CALLIMS LU6.2 for IMS/TM.** This procedure connects to IMS/TM using an IMS/APPC connection from a server for z/OS.
- **CALLITOC OTMA for IMS/TM.** This procedure is available on all servers beginning with Version 5 Release 1.0.

The CALLIMS and CALLITOC procedures for IMS/TM hide the complexity of accessing IMS/TM transactions from the client application. The client application uses any major *standard* access protocol to connect to a server and invoke the adapter to access the IMS/TM transaction. The standard protocols include ODBC, JDBC, OLE DB, or any enabled client or connector.

The Adapter for IMS Transactions allows any client or connector to invoke a transaction running under the control of an IMS/TM transaction-processing monitor. It provides a means of building on existing applications that perform transaction processing against IMS/TM, to create new Web or client/server applications while reusing existing IMS transactions and program logic.

For related information, refer to the *API Reference* manual for API method calls and the *Stored Procedure Reference* manual for details about writing Dialogue Manager procedures.

CALLIMS Procedure for IMS/TM

The CALLIMS procedure is part of the server for z/OS. It is attached to and extended from any compatible API environment, including client applications and Hub Servers.

The CALLIMS procedure uses LU6 communications from a server for z/OS to execute IMS/TM transactions, and passes the output to any client that connects to that server.

CALLITOC OTMA Procedure for IMS/TM

The OTMA procedure fully utilizes the IMS TOC functionality. The IMS TCP/IP Connector (ITOC) and its equivalent product, IMS Connect, is available with IMS Version 7.1 and higher, and allows client TCP/IP communications to and from one or more IMS/TM regions. TOC and IMS Connect are IBM's implementation for allowing the execution of IMS/TM transactions from TCP/IP clients.

Transaction Processing With CALLIMS or CALLITOC

The following steps are performed when a client application calls an IMS/TM transaction using either the CALLIMS or CALLITOC procedure. The difference between the CALLIMS and the CALLITOC procedures is the communications method used to connect to the IMS/TM region from the client application. Also, CALLIMS requires a server for z/OS to initiate the IMS/TM request. Any client on any platform can connect to the server for z/OS.

1. The client application issues the API method call, EDARPC, to run a Dialogue Manager procedure residing on a server (either a Hub Server or a Full-Function Server).

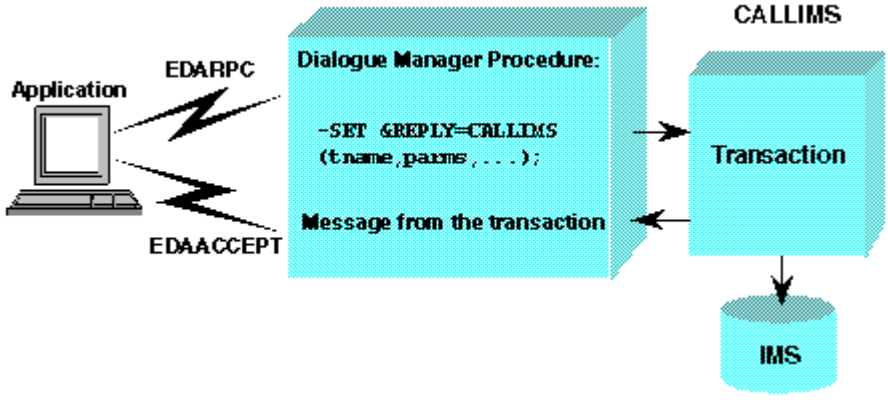
   Parameters are sent as part of the calling sequence for use by the procedure.

2. The Dialogue Manager procedure contains the command -SET, which executes CALLIMS or CALLITOC.
3. CALLIMS or CALLITOC establishes a connection to the IMS/TM environment and invokes the transaction, passing an IMS message as a parameter.
4. The IMS transaction receives and then processes the input message. It then passes one IMS message back to the server. The CALLIMS or CALLITOC procedure returns the message to the client application.
5. The client application issues the method call, EDAACCEPT, to accept the message.

For details on the syntax and use of API method calls, see the *API Reference* manual.

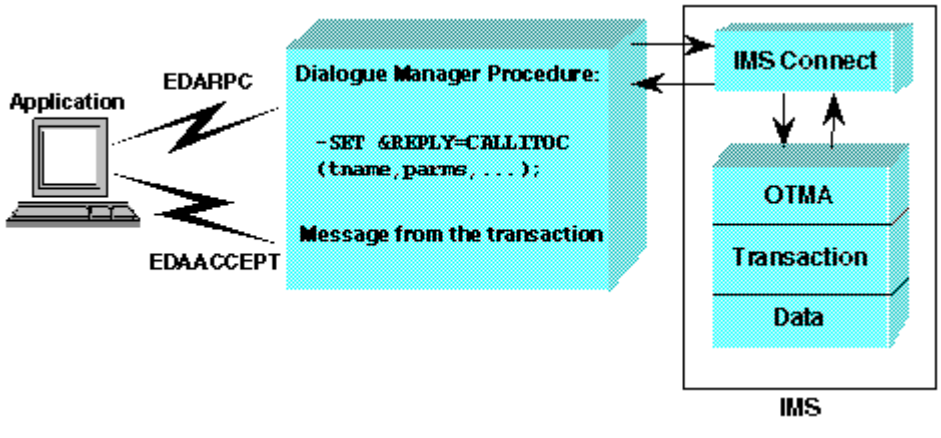
Example: Processing a Transaction With CALLIMS

The following figure illustrates transaction processing as initiated by the client application running a CALLIMS request.



Example: Processing a Transaction With CALLITOC OTMA

The following figure illustrates transaction processing as initiated by the client application running a CALLITOC OTMA request.



Using CALLIMS and CALLITOC

To call an IMS/TM transaction, execute either CALLIMS or CALLITOC from a Dialogue Manager procedure:

- CALLIMS invokes an IMS/TM transaction through the use of APPC/IMS. CALLIMS requires IMS Version 4.1 or higher (IMS/TM) and APPC.
- CALLITOC invokes an IMS/TM transaction through the use of IMS TOC or IMS Connect. CALLITOC requires IMS Version 5.1 or higher (IMS/TM) and a TOC or IMS connection to an IMS OTMA address space.

A sample RPC called CALLIMSC is supplied with the Server. It executes the IMS/TM PART transaction for verification and installation purposes.

Reference: Differences Between CALLIMS and CALLITOC

There are several differences between the CALLIMS and the CALLITOC procedures:

- The communications method used to connect to the IMS/TM region from the client application. CALLIMS uses LU6.2, CALLITOC uses TCP/IP to the mainframe using IMS Connect.
- CALLIMS requires a server for z/OS to initiate the IMS/TM request.
- For CALLIMS, you must run a separate link job to allow CALLIMS to communicate with APPC. For details, see *Installing CALLIMS* on page 1103.

How Data Is Returned With CALLIMS and CALLITOC

CALLIMS and CALLITOC return codes and data to the client application in a series of 72-byte messages. To retrieve the messages, the client application issues the method call EDAACCEPT.

Repeated calls to EDAACCEPT retrieve all messages from CALLIMS and CALLITOC.

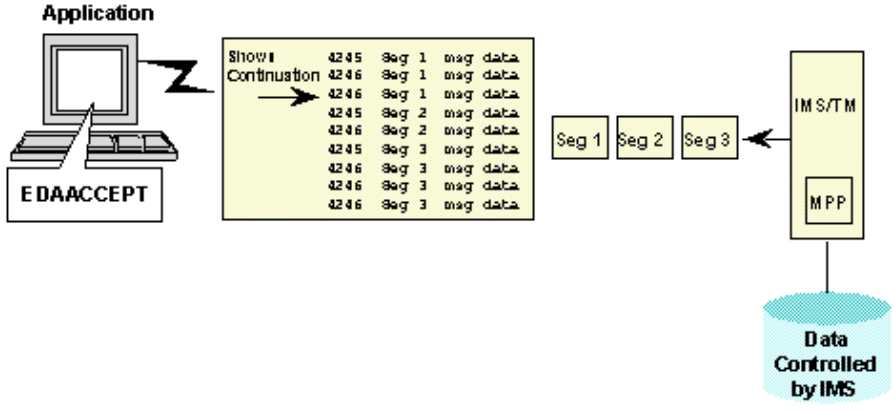
The client application must check the message code in the field scb.msg_code. (The session control block contains several fields pertaining to message processing. For example, scb.msg_code contains a message code and scb.msg_text contains the message text.)

A code of 4245 indicates that the message is coming from CALLIMS or CALLITOC.

For the client application to detect multiple output segments, the Adapter for IMS Transactions returns a message code of 4246 following the 4245, until the end of the segment. At that time, the message code is again 4245, indicating the beginning of a new segment.

Example: **Viewing Message Codes From CALLIMS or CALLITOC**

The following figure illustrates the message codes from CALLIMS or CALLITOC when there are multiple output segments. The client application normally changes the received format to a format acceptable to the end user.



Installing CALLIMS

Complete the following installation steps:

1. *Step 1: Ensure That You Have the Required Hardware and Software*
2. *Step 2: Determine the APPC Setup*
3. *Step 3: Set the Security Level*
4. *Step 4: Link-edit the API*
5. *Step 5: Confirm Interaction With IMS/TM*

Step 1: Ensure That You Have the Required Hardware and Software

CALLIMS requires the following hardware and software:

- ❑ An IBM or IBM-compatible mainframe running z/OS 1.7 or higher. For the latest release information see Information Builders Technical Support web site.
- ❑ APPC Services.
- ❑ An IBM Supported version of IMS.

Step 2: Determine the APPC Setup

CALLIMS communicates with APPC to execute IMS/TM transactions. APPC includes an interface to IMS called APPC/IMS. The APPC/IMS interface must be correctly configured to support IMS/TM transactions.

APPC components that may be used by CALLIMS include:

- **APPLID for the IMS region.** This APPLID identifies applications executing IMS/TM transactions from LU6.2 devices.
- **APPC side information data set.** This data set contains records keyed by a symbolic destination name. This is a client/server feature of APPC that enables a site to establish default information for an application attempting to execute IMS/TM transactions. Each record may contain default APPLIDs, log mode table names, and IMS transaction names.
- **TP profile data set.** This data set enables a site to substitute application-oriented transaction names with a real IMS transaction name. For example, assume that an application refers to a transaction named NAMECHG. The actual transaction (translated in the TP Profile Data set) may be SSNUPDT.

Note: The APPC Transaction Scheduler (ASCH) must be fully configured and running in order for CALLIMS to communicate successfully with APPC/IMS. See the appropriate IBM APPC documentation for configuration instructions.

Step 3: Set the Security Level

To establish conversation security with APPC/IMS, define the environment under which the partner (the other end of the conversation with IMS/TM) will run.

The two possible security levels are:

- **Security Same.** Specifies that the transaction invoked by CALLIMS be run under the same security environment as the calling function (CALLIMS). The security environment includes the user ID and possibly the security profile name of the application.

  This security level is the default if no security information is explicitly provided in the CALLIMS function.
- **Security Program.** Specifies that the application provide a user ID, password, and security profile name to establish the security environment. This security level allows the partner to verify the information, and occurs when the information is provided to the Dialogue Manager procedure in which CALLIMS is invoked.

Step 4: Link-edit the API

The CALLIMS subroutine communicates with APPC using the APPC API. To establish communication between CALLIMS and APPC, you must link-edit the API.

To link-edit the API, submit the following job

qualif.HOME.DATA(GENEAPPC)

where:

qualif

Is the high-level qualifier for the data sets.

Example: Installing CALLIMS

The following JCL is located in member GENEAPPC in the library qualif.HOME.DATA. It must be modified and run.

```
//*******************************************************************
//* NAME:     GENEAPPC JCL
//*
//* FUNCTION: LINKEDIT APPC STUBS INTO CALLIMS
//*
//* PROC SYMBOLIC PARAMETERS:
//*       1. qualif MUST BE CHANGED TO THE HIGH LEVEL QUALIFIER
//*          USED FOR THE PROGRAM DATASETS UNLOAD FROM THE MEDIA
//*
//*******************************************************************

//APPROC  PROC PREFIX='qualif'
//*
//LKED    EXEC PGM=IEWL,PARM='RENT,LIST,NOXREF,LET'
//SYSLIB   DD DISP=SHR,DSN=SYS1.CSSLIB
//SYSIN    DD DISP=SHR,DSN=&PREFIX..HOME.LOAD
//SYSLMOD  DD DISP=SHR,DSN=&PREFIX..HOME.LOAD
//* Switch the above two lines with the following for PDS deployment
//*SYSIN    DD DISP=SHR,DSN=&PREFIX..P.HOME.LOAD
//*SYSLMOD   DD DISP=SHR,DSN=&PREFIX..P.HOME.LOAD
//SYSUT1   DD UNIT=SYSDA,SPACE=(100,(50,50))
//SYSPRINT DD SYSOUT=A
//*
//APPROC   PEND
//GENFAPPC EXEC APPROC
//LKED.SYSLIN   DD *
  INCLUDE SYSIN(CALLIMS)
  INCLUDE SYSLIB(ATBPBI)
  MODE AMODE(31),RMODE(ANY)
  ENTRY CALLIMS
  NAME CALLIMS(R)
/*
```

Step 5: Confirm Interaction With IMS/TM

The Transaction Server for IMS provides a sample REXX EXEC that helps confirm the successful installation of APPC and APPC/IMS. The EXEC will invoke an existing MPP.

To use the sample EXEC, which is located in *qualif*.HOME.DATA(APPCIVP):

1. You may need to change the default EXEC values to execute the IMS IVP PART transaction.

   The following table lists and describes the default values:

Values	Description
`TP_name = 'PART'`	The name of the transaction to invoke.
`Sym_dest_name = 'IMSDEST'`	The symbolic destination name found in the side information data set.
`Mode_name = 'LU62APPC'`	The log mode table entry name used by the LU6.2 APPLID supplied on the next keyword.
`Partner_LU_Name = 'SCMI41AX'`	The LU6.2 APPLID defined for use by APPC/IMS.
`Partnumber = 'AN960C10'`	The input data for the transaction.

2. In case of errors, APPCIVP calls a standard REXX EXEC named IRXCKRC, so you must copy the EXEC from SYS1.SAMPLIB to *qualif*.HOME.DATA.
3. After you make the necessary changes to APPCIVP and copy IRXCKRC, run the EXEC from TSO:

   ```
   EX 'qualif.HOME.DATA(APPCIVP)' EXEC
   ```

   This routine confirms that APPC/IMS is correctly configured to operate in a client/server environment. The next step enables the server to initiate an IMS connection.

Executing CALLIMS and CALLITOC

CALLIMS or CALLITOC is executed from a Dialogue Manager procedure with the command -SET.

Any of the variables described in the syntax that follows may be implicitly set in the Dialogue Manager procedure using the command -DEFAULTS, or explicitly set on the CALLIMS or CALLITOC call. The variables work the same way, whether set implicitly or explicitly. If both ways are used, the explicit setting takes precedence over the implicit setting. For examples of implicit settings, see *Using -SET to Execute CALLITOC* on page 1111 and *Using -SET to Execute CALLIMS* on page 1110.

Syntax: How to Execute CALLIMS

The dash (-) in the syntax below is used to allow multiple lines for a parameter list in a Dialogue Manager command, as in -SET

```
-SET &REPLY = CALLIMS(&SYM,&TP,&MLEN,&MSG,&DELIM,&OPT,&UID,
- &PW,&SG,&PLU,&LMODE,&HEXCONV,'A1') ;
```

where:

&SYM

Is the symbolic destination name. This is a key value for the side information data set configuration file defined to APPC. APPC supports a symbolic destination name for determining the default APPLID for the IMS/TM region, with a log mode and transaction name. If a value is supplied for &SYM, either implicitly or explicitly, then &TP, &PLU, and &LMODE may be left blank. This field must be 8 characters in length.

&TP

Is the name of the IMS MPP transaction. This field must be 8 characters in length. Set &TP to blanks if you supply a value for &SYM.

&MLEN

Is the length of the IMS MPP message for the transaction. This is set with the Dialogue Manager LENGTH function in a -SET command.

&MSG

Is the input message for the IMS transaction. This message must exactly match the layout expected by the transaction.

&DELIM

Is a non-blank character string used to delimit individual segments in this IMS message. Each delimited segment has its own SEND. This variable is designed for MPP transactions that expect to retrieve multiple segments from the message queue. The length of &DELIM must be 4 characters.

&OPT

Specifies whether CALLIMS waits for a response. Possible values are:

REPL assumes synchronous operation. CALLIMS waits for a return code or other response from IMS/TM.

NORP sends the message, then immediately returns control to the server. CALLIMS does not wait for a response.

The length of &OPT must be 4 characters.

The following parameters are optional. If not used, the parameters must be padded with blanks.

&UID

Is the user ID that invokes the IMS MPP transaction. The length of &UID must be 8 characters.

&PW

Is the password used to invoke the IMS MPP transaction. The length of &PW must be 8 characters.

&SG

Is the security group that the user ID belongs to or is part of. The length of &SG must be 8 characters.

&PLU

Is the LU6.2 APPLID for the IMS/TM region. The length of &PLU must be 8 characters. Set &PLU to blanks if you supply a value for &SYM.

&LMODE

Is the log mode table entry name. The length of &LMODE must be 8 characters. Set &LMODE to blanks if you supply a value for &SYM.

HEXCONV

A value of ON will truncate the message returned after any hex character data. OFF is the default.

'A1'

Sets the format of the response to alphanumeric. It is required by -SET.

Syntax: How to Execute CALLITOC OTMA

The dash (-) in the syntax below is used to allow multiple lines for a parameter list in a Dialogue Manager command, as in -SET

```
    -?SET &REPLY = CALLITOC(&HOST, &PORT, &DSID, &TPNAME, &MLEN, &MESSAGE,
-? &USERID, &RUSERID, &RGROUP, &PASSWD, &DELIM, &HEXCONV, &OPTION, &OTMAEX 'A1');
```

where:

`&HOST`

Is the symbolic destination name. TCP/IP is the host address where IMS Connect or ITOC is running. *&host* is the value in the HOSTNAME=*host* in the HWS configuration file.

`&PORT`

Is the port number that IMS Connect or ITOC is listening on. *&port* is the value in the PORTID=*port* in the HWS configuration file.

`&DSID`

Is the value in the DATASTORE ID=*dsid* in the HWS configuration file.

`&TPNAME`

Is the name of the IMS MPP transaction. This field must be 8 characters in length.

`&MLEN`

Is the length of the IMS MPP message for the transaction. This is set with the Dialogue Manager LENGTH function in a -SET command.

`&MESSAGE`

Is the input message for the IMS transaction. This message must exactly match the layout expected by the transaction.

`&USERID`

Is the ITOC user ID. This user ID is reserved for future use.

`&RUSERID`

Is the user ID that is validated by RACF based on the RGROUP value.

`&RGROUP`

Is the XCF group validated by RACF. *&rgroup* is the value in the GROUP=*rgroup* in the HWS configuration file.

`&PASSWD`

Is the RACF password based on the RUSERID value.

`&DELIM`

Is a non-blank character string used to delimit individual segments in this IMS message. Each delimited segment has its own SEND. This variable is designed for MPP transactions that expect to retrieve multiple segments from the message queue. The length of &DELIM must be 4 characters.

`&HEXCONV`

A value of ON will truncate the message returned after any hex character data. OFF is the default.

`&OPTION`

Specifies whether CALLITOC waits for a response. Possible values are:

`REPL` assumes synchronous operation. CALLITOC waits for a return code or other response from IMS/TM.

`NORP` sends the message, then immediately returns control to the server. CALLITOC does not wait for a response.

The length of &OPT must be 4 characters.

`&OTMAEX`

Specifies which user message exit to use:

- *SAMPLE* indicates HWSSMPL0
- *SAMPL1* indicates HWSSMPL1

The sample user exits enable users to assign their own message formats to fit their business needs. See the IBM documentation for further information about sample user exits.

`'A1'`

Sets the format of the response to alphanumeric. It is required by -SET.

Example: Using -SET to Execute CALLIMS

The following is a sample Dialogue Manager procedure that uses the command -SET to execute CALLIMS. It is member CALLIMS of the data set.

In this example, values for variables are padded with blanks as required. The command -DEFAULTS enables you to specify default values in the Dialogue Manager procedure, but may be overridden by a client application:

```
-DEFAULTS &SYM    = '        '
-DEFAULTS &TP     = 'PART    '
-DEFAULTS &MSG    = 'AN960C10'
-DEFAULTS &DELIM  = '    '
-DEFAULTS &OPT    = 'REPL'
-DEFAULTS &UID    = '        '
-DEFAULTS &PW     = '        '
-DEFAULTS &SG     = '        '
-DEFAULTS &PLU    = 'SCMI41AX'
-DEFAULTS &LMODE  = 'LU62APPC'
-SET &MLEN  = &MSG.LENGTH;
-SET &REPLY =
CALLIMS(&SYM,&TP,&MLEN,&MSG,&DELIM,&OPT,&UID,&PW,&SG,&PLU,&LMODE,'A1');
```

Example: **Using -SET to Execute CALLITOC**

The following is a sample Dialogue Manager procedure that uses the command -SET to execute CALLITOC. For a server for MVS, it is member CALLIMS of the data set.

In this example, values for variables are padded with blanks as required.

```
-DEFAULT   &HOST=    'IBIMVS.IBI.COM ';
-DEFAULT   &PORT=     6683;
-DEFAULT   &DSID=    'IMS61          ';
-DEFAULT   &TPNAME=  'PART           ';
-DEFAULT   &OPTION=  'REPL           ';
-DEFAULT   &MESSAGE= 'AN960C10       ';
-DEFAULT   &USERID=  '               ';
-DEFAULT   &RUSERID= '               ';
-DEFAULT   &RGROUP=  'IMSGRP61       ';
-DEFAULT   &PASSWD=  '               ';
-DEFAULT   &DELIM=   '               ';
-DEFAULT   &HEXCONV= '               ';
-DEFAULTS  &OTMAEX = '*SAMPLE*'

-SET &MLEN = &MESSAGE.LENGTH;

-SET &REPLY = CALLITOC(&HOST,
-                     &PORT,
-                     &DSID,
-                     &TPNAME,
-                     &MLEN,
-                     &MESSAGE,
-                     &USERID,
-                     &RUSERID,
-                     &RGROUP,
-                     &PASSWD,
-                     &DELIM,
-                     &HEXCONV,
-                     &OPTION,
-                     &OTMAEX,
-                     'A1') ;
```

Storing Multiple Messages In a Server File for Later Queries

If you are using a front-end application, such as PowerBuilder, which cannot handle multiple messages, a method is needed to convert the messages into an answer set. This is especially important when using CALLIMS or CALLITOC, which only return messages.

Example: Storing Multiple Messages for Later Execution

The following stored procedure executes a CALLIMS procedure that returns 5 messages. Instead of sending the messages directly to the client, the stored procedure stores the messages in a file. A subsequent SELECT is performed to extract data, as an answer set, from the file. The stored procedure statements required for saving messages in the file are highlighted.

```
-SET &EMGSRV = 'FILE';
DYNAM ALLOC FILE EMGFILE DA qualif.EMGFIL SPACE 2,2 TRACKS UNIT SYSDA -
RECFM FB LRECL 80 BLKSIZE 1600
SET EMGSRV=&EMGSRV
SET PAUSE=OFF
-RUN
-DEFAULT &SYM  = '        '
-DEFAULT &TP   = 'PART    '
-DEFAULT &MSG  = 'AN960C10'
-DEFAULT &DELIM= '        '
-DEFAULT &OPT  = 'REPL    '
-DEFAULT &UID  = '        '
-DEFAULT &PW   = '        '
-DEFAULT &SG   = '        '
-DEFAULT &PLU  = 'SCMI41AX'
-DEFAULT &LMODE= 'LU62APPC'

-SET &MLEN = &MSG.LENGTH ;
-SET &REPLY = CALLIMS(&SYM,&TP,&MLEN,&MSG,&DELIM,&OPT,&UID,
- &PW,&SG,&PLU,&LMODE,'A1') ;

DYNAM FREE DDN EMGFILE
-RUN
DYNAM ALLOC FILE EMGSRV1 DA qualif.EMGFIL SHR REU
-RUN
SQL
SELECT COL1 FROM EMGSRV1;
TABLE
ON TABLE PCHOLD FORMAT ALPHA
END
DYNAM FREE DDN EMGSRV1
-RUN
```

For the SELECT COL1 FROM EMGSRV1 statement to work, a Master File has to be predefined for the file. The following is the Master File, EMGSRV1, used for this example:

```
FILENAME=EMGSRV1,SUFFIX=FIX
SEGNAME=ORIGIN,SEGTYPE=S1
 FIELDNAME=COL1,FIRST40,A40,$
 FIELDNAME=COL2,LAST40,A40,$
```

The following is the output, from CALLIMS, which is placed into the file:

```
(FOC4245)  :      Part...........     AN960C10; Desc.......... WASHER
(FOC4246)  :
(FOC4245)  :      Proc Code......           74; Inv Code.......        2
(FOC4245)  :      Make Dept......        12-00; Plan Rev Num...
(FOC4245)  :      Make Time......           63; Comm Code......       14
```

Note: The second line is a FOC4246 message line, which indicates a continuation of the previous line. The sample stored procedure returns the first 40 bytes of all 5 records to the client. The stored procedure can be set to return the entire message.

Chapter 40

Using the Adapter for Informix

The Adapter for Informix allows applications to access Informix data sources. The adapter converts application requests into native Informix statements and returns optimized answer sets to the requesting application. This adapter has read/write capabilities, which enables the adapter to insert the data from an application to the data source.

In this chapter:

Preparing the Informix Environment

The Adapter for Informix minimally requires the installation of the Informix Client SDK software. The Informix Client SDK software allows you to connect to a local or remote Informix database server.

In order to support a greater range of Informix DBMS releases, the current server release uses Informix Client SDK in its Adapter for Informix. All the current Informix Client SDKs support connectivity to wide range of Informix databases. For example, SDK 2.6 will support connectivity to Informix releases 5.1 through 9.3.

Note: Always check the Informix SDK documentation for supported releases of Informix databases.

The following environment settings apply when configuring the server with the Adapter for Informix.

Procedure: How to Set Up the Environment on Windows

On Windows, the Informix environment is set up during the installation of the Informix Server and Informix Client SDK.

If necessary, change the environment variable DBDATE. DBDATE determines how Informix handles conversion between character strings and relational columns of DATE type. If you want to code SQL statements containing date literals in any format other than Y4MD- you must:

1. Ensure that the exported DBDATE value is set to the required date format. Use the Registry Editor (regedit) to search for and clear all registry keys that refer to DBDATE, and then assign the new value to DBDATE using the Informix SDK SetNet program.
2. Specify DBDATE_OVERRIDE OFF in the server profile to ensure that the Adapter for Informix does not override the exported DBDATE value.

   By default, the adapter overrides the values of DBDATE with the value of Y4MD-.

   For more information about DBDATE_OVERRIDE, see *How to Change the Way the Adapter Handles DBDATE* on page 1117.

For example, if you want to code an SQL statement containing a date literal formatted as mm/dd/yyyy (such as 12/31/2006) and execute it using Direct SQL Passthru, you would change the value of DBDATE to 'MDY4/'.

However, it is strongly advised that your applications use the ISO-compatible format Y4MD- for date literals (for example, '2005-12-31'). By doing so, you avoid the need to export DBDATE and to set DBDATE_OVERRIDE.

Procedure: How to Set Up the Environment on UNIX

1. Identify the Informix Client SDK using the UNIX environment variable $INFORMIXDIR. For example, to use SDK 2.9, you would assign its home directory, /rdbms4/isdk29, to INFORMIXDIR:

   ```
   INFORMIXDIR=/rdbms4/isdk29
   export INFORMIXDIR
   ```

2. Identify the server name, as it is specified in the SDK's SQLHOSTS file, using the UNIX environment variable $INFORMIXSERVER:

   ```
   INFORMIXSERVER=server_name
   export INFORMIXSERVER
   ```

3. Specify the path to the Informix shared library using the UNIX environment variable $LD_LIBRARY_PATH. For example:

   ```
   LD_LIBRARY_PATH=$INFORMIXDIR/lib:$LD_LIBRARY_PATH
   export LD_LIBRARY_PATH
   ```

4. If necessary, change the environment variable DBDATE.

   DBDATE determines how Informix handles conversion between character strings and relational columns of DATE type. If you want to code SQL statements containing date literals in any format other than Y4MD- you must:

   a. Ensure that the exported DBDATE value is set to the required date format.

   b. Specify DBDATE_OVERRIDE OFF in the server profile to ensure that the Adapter for Informix does not override the exported DBDATE value.

      By default, the adapter overrides the values of DBDATE with the value of Y4MD-.

      For more information about DBDATE_OVERRIDE, see *How to Change the Way the Adapter Handles DBDATE* on page 1117.

   For example, if you want to code an SQL statement containing a date literal formatted as mm/dd/yyyy (such as 12/31/2006) and execute it using Direct SQL Passthru, you would change the value of DBDATE to 'MDY4/':

   ```
   DBDATE=MDY4/
   export DBDATE
   ```

   However, it is strongly advised that your applications use the ISO-compatible format Y4MD- for date literals (for example, '2005-12-31'). By doing so, you avoid the need to export DBDATE and to set DBDATE_OVERRIDE.

Syntax:

How to Change the Way the Adapter Handles DBDATE

It is recommended that you do not change the way the Adapter for Informix works with the DBDATE environment variable. However, if it is necessary, you can do so by issuing the following command

```
SQL SQLINF SET DBDATE_OVERRIDE {ON|OFF}
```

where:

ON

Sets the DBDATE environment variable to 'Y4MD-' at the moment that the adapter connects to an Informix database.

ON is the default value.

OFF

Ensures that the DBDATE value, at the moment that the adapter connects to an Informix database, is the same value that was in effect immediately after the adapter's environment was set up.

It is recommended that you issue SET DBDATE_OVERRIDE only in the server profile. If it is absolutely necessary to change the value of DBDATE within an individual procedure, one must understand exactly when the new value for DBDATE actually takes effect.

The current value of DBDATE is communicated to the Informix database by the Informix client at the moment that it connects to the database, and remains in effect until the Informix client disconnects from the database. The Adapter for Informix supports multiple concurrent connections. The adapter connects to the Informix database when the adapter starts executing a command that references objects that reside in that database. By default, the adapter does not disconnect until the end of the server agent's session. Setting DBDATE does not affect current connections to the database unless you force the adapter to reconnect. You can force it to reconnect by issuing the following commands:

```
SQL SQLINF SET AUTODISCONNECT ON COMMAND
SQL SQLINF END SESSION
```

Accessing a Remote Informix Server

Using the standard rules for deploying the Informix Client, the server supports connections to:

- Local Informix database servers.
- Remote Informix database servers. To connect to a remote Informix database server, the sqlhosts file on the source machine must contain an entry pointing to the target machine and the listening process must be running on the target machine.

Informix SQL ID (for Informix SE only)

When you access Informix SE, you are identified by your UNIX login ID. The UNIX ID becomes the owner ID for any Informix objects (such as tables or indexes) created with immediate SQL commands. Immediate commands are non-parameterized SQL statements that are passed directly to the data source. The UNIX ID is also used as the sole authorization ID for Informix GRANT and REVOKE statements.

Other types of requests, such as SQL SELECTs, sponsor an Informix search for the necessary privileges to act on the particular tables and views in a data source using the UNIX ID. All Informix security rules are respected.

The following table shows the UNIX privileges required in order to specify certain SQL statements.

Statement	Requires
SELECT	Read permission for the Informix data and index files. UNIX write and execute (search) privileges for the data source directory.
UPDATE	Write permission for the Informix data and index files. UNIX write and execute (search) privileges for the data source directory.

ANSI-Compliant Data Sources

If you create a data source to be ANSI-compliant, owner naming is enforced by Informix. Therefore, to preserve any lowercase owner name, you must enclose it in double quotation marks. Otherwise, Informix will default to uppercase for the owner name. For example:

```
ENGINE SQLINF
SELECT * FROM "user1".test
END
```

For additional information, see the *Informix Guide to SQL*.

XA Support

Read/write applications accessing Informix data sources are able to perform transactions managed in XA-compliant mode.

To activate the XA Transaction Management feature, the server has to be configured in Transaction Coordination Mode, using the Web console configuration functions. Using Transaction Coordination Mode guarantees the integrity of data modification on all of the involved DBMSs and protects part of the data modifications from being committed on one DBMS and terminated on another.

For complete documentation on XA compliance, see *XA Support* on page 2689.

Configuring the Adapter for Informix

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to an Informix database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one Informix database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to Informix Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Informix

The *Informix* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

Informix server name, as defined by the dbservername field in the sqlhosts file.

Security

There are three methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.
- **Trusted.** The adapter connects to the database using the database rules for an impersonated process that are relevant to the current operating system.

User

Name by which the user is known to Informix.

Password

Password associated with the user name.

Database name

Informix database name. For:

- **Informix SE,** specify the entire path to the location of the database files including the database name, but without the dbs extension.
- **Informix Online and Informix Dynamic Server,** specify the database name, but without the dbs extension.

DB_LOCALE

Specifies the database locale, which is what the database server uses to process locale-sensitive data.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

Explicit authentication. The user ID and password are explicitly specified for each connection and passed to Informix, at connection time, for authentication.

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES [connection]
 [datasource]/userid,password ;dbname
```

Password passthru authentication. The user ID and password are explicitly specified for each connection and passed to Informix, at connection time, for authentication.

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES [connection]
 [datasource]/;dbname
```

Trusted authentication. The adapter connects to Informix as a Windows login using the credentials of the Windows user impersonated by the server data access agent.

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES [connection]
 [datasource]/,;dbname
```

where:

SQLINF

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is a logical name (or a data source name) used to identify this particular set of attributes.

If you plan to have only one connection to Informix, this parameter is optional. If not specified, the local database server serves as the default connection.

datasource

Is the name of the database server as defined by the dbservername field in the sqlhosts file.

If datasource is not specified, the Informix default server (value of the INFORMIXSERVER environment variable) is used. You can also specify the default server with two consecutive single quotation marks.

userid

Is the primary authorization ID by which you are known to Informix.

password

Is the password associated with the primary authorization ID.

dbname

Also referred to as schema, is the name of the Informix database used for this connection. For:

- **Informix SE,** specify the entire path to the location of the database including the database name, but without the dbs extension. Enclose the entire value in single quotation marks.
- **Informix Online and Informix Dynamic Server,** specify the database name, but without the dbs extension.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command allows the application to access the Informix database mydir1/mydir2/sampdb on the Informix database server named SAMPSERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

- For Informix SE:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES SAMPSERVER/MYUSER,PASS; 'mydir1/
mydir2/sampdb'
```

- For other versions of Informix:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES SAMPSERVER/MYUSER,PASS; SAMPDB
```

The following SET CONNECTION_ATTRIBUTES command connects to the Informix database server named SAMPLESERVER using Password Passthru authentication:

- For Informix SE:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES SAMPSERVER/; 'mydir1/mydir2/
sampdb'
```

- For other versions of Informix:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES SAMPSERVER/; SAMPDB
```

The following SET CONNECTION_ATTRIBUTES command connects to a local Informix database server using operating system authentication:

- For Informix SE:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES /,;'mydir1/mydir2/sampdb'
```

- For other versions of Informix:

```
ENGINE SQLINF SET CONNECTION_ATTRIBUTES /,; SAMPDB
```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLINF SET DEFAULT_CONNECTION connection
```

where:

`SQLINF`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLINF SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLINF SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

SQLINF

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN

Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Informix Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the data source structure and the server mapping of the Informix data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Informix table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for the extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.

- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Informix

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Database selection

To specify a database from which you can select a table or other object, do one of the following:

- Check *Use current database* to use the database that has been set as the default database.
- Select a database from the *Select database* drop-down list, which lists all databases in the current DBMS instance.

  Before selecting a database, if Use current database is checked, uncheck it.

This option does not apply to Informix SE, for which *Use current database* must be checked.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.
- In the *Document Name* field, enter the file name with or without wild card characters.
- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  ```
  /QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE
  ```

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Informix synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLINF ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,     DIVISION4,     I9,  I4,  MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON  ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9,  I4,  MISSING=ON  ,$
```

Generated Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=qatst:"edaqa".nf29004,
CONNECTION=conn_inf,KEYS=1,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Attribute	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Informix table name. The table name can be fully qualified as follows: TABLENAME=[[*database*.]*owner*.]*table*

Attribute	Description
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local Informix database server. Absence of the CONNECTION attribute indicates access to the default database server.
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Attribute	Description
AUTO INCREMENT	Set to Yes to enable autoincrementing.
START	Initial value in incrementing sequence
INCREMENT	Increment interval.
INDEX_NAME INDEX_UNIQUE INDEX_COLUMNS INDEX_ORDER	Indicate a name of the index in a database, uniqueness, name, and order of the indexed column(s).

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Informix Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Controlling the Mapping of Variable-Length Data Types

The SET parameter VARCHAR controls the mapping of the Informix data types VARCHAR, VARCHAR2, and NVARCHAR2. By default, the server maps these data types as variable character (A*n*V).

The following table lists data type mappings based on the value of VARCHAR:

Informix Data Type	Remarks	VARCHAR ON		VARCHAR OFF	
LVARCHAR (*n*)		A2048V	A2048V	A2048	A2048

Informix Data Type	Remarks	VARCHAR ON		VARCHAR OFF	
NVARCHAR (*n*)		A255V	A255V	A255	A255

Syntax: How to Control the Mapping of Variable-Length Data Types

```
ENGINE SQLINF SET VARCHAR {ON|OFF}
```

where:

SQLINF

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Maps the Informix data types VARCHAR, VARCHAR2, and NVARCHAR2 as variable-length alphanumeric (A*n*V). ON is the default value.

OFF

Maps the Informix data types VARCHAR, VARCHAR2, and NVARCHAR2 as alphanumeric (A).

Trailing Blanks in SQL Expressions

The new SQL Expression generator in the TABLE Adapter by default preserves literal contents, including trailing blanks in string literals and the fractional part and exponential notation in numeric literals. This allows greater control over the generated SQL.

In some rare cases when trailing blanks are not needed, the following syntax

```
ENGINE SQLINF SET TRIM_LITERALS ON
```

is available to ensure backward compatibility.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the Informix Environment

The Adapter for Informix provides several parameters for customizing the environment and optimizing performance.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLINF SET PASSRECS {ON|OFF}
```

where:

`SQLINF`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Activating NONBLOCK Mode

The Adapter for Informix has the ability to issue calls in NONBLOCK mode. The default behavior is BLOCK mode.

This feature allows the adapter to react to a client request to cancel a query while the adapter is waiting on engine processing. This wait state usually occurs during SQL parsing, before the first row of an answer set is ready for delivery to the adapter or while waiting for access to an object that has been locked by another application.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Activate NONBLOCK Mode

```
ENGINE SQLINF SET NONBLOCK {0|n}
```

where:

`SQLINF`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

n

Is a positive numeric number. 0 is the default value, which means that the adapter will operate in BLOCK mode. A value of 1 or greater activates the NONBLOCK calling and specifies the time, in seconds, that the adapter will wait between each time it checks to see if the:

- Query has been executed.
- Client application has requested the cancellation of a query.
- Kill Session button on the Web Console is pressed.

Note: A value of 1 or 2 should be sufficient for normal operations.

Using a Quoted Identifier

The QUOTED_IDENTIFIER setting enables the adapter for Informix to set the Informix environment variable DELIMIDENT, which determines whether the database server interprets strings enclosed in double quotation marks as SQL identifiers or as literal strings.

When the DELIMIDENT environment variable is set to ON, the adapter generates SQL with double quotation marks around identifiers such as table names and column names, when necessary. (For details about the effects of setting the DELIMIDENT environment variable, refer to the Informix documentation.)

The DELIMIDENT environment variable is passed to the Informix database by the Informix client at the moment the client connects to the database; the variable remains in effect until the Informix client disconnects from the database. The adapter connects to the Informix database when the adapter starts executing a command that references objects residing in that database. By default, the adapter does not disconnect until the end of the server agent session. Setting DELIMIDENT does not affect current connections to the database unless you force the adapter to reconnect. You can force it to reconnect by issuing the following commands:

```
SQL SQLINF SET AUTODISCONNECT ON COMMAND
SQL SQLINF END SESSION
```

Tip: You can change this setting manually, or change it from the Web Console by clicking Data Adapters in the menu bar, clicking the name of a configured adapter, and choosing *Change Setting*s from the menu.

Note: The DELIMIDENT variable is supported by the Dynamic, XPS, and SE Informix Servers. However, it is not supported by Informix Online.

Syntax: How to Enable Quoted Identifiers Around Strings

```
ENGINE SQLINF SET QUOTED_IDENTIFIER {OFF|ON}
```

where:

`SQLINF`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`OFF`

Indicates that strings enclosed in double quotation marks are to be interpreted as literal strings. OFF is the default value.

`ON`

Indicates that strings enclosed in double quotation marks are to be interpreted as SQL identifiers.

Informix Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109 and *Optimizing Requests to Pass Virtual Fields Defined as Constants* on page 112.

Calling an Informix Stored Procedure Using SQL Passthru

Informix stored procedures are supported using SQL Passthru. These procedures need to be developed within Informix using the CREATE PROCEDURE command.

The adapter supports all scalar parameters: IN, OUT, and INOUT.

Example: Calling a Stored Informix Procedure

The supported syntax to call a stored procedure is shown below. It is recommended that you use the syntax below instead of the previously supported CALLINF syntax.

```
ENGINE SQLINF
EX SAMPLE PARM1,PARM2,PARM3...;
TABLE ON TABLE PCHOLD
END
```

Example: Informix Stored Procedure

```
CREATE PROCEDURE SAMPLE()
RETURNING CHAR(11), CHAR(20), CHAR(15), DATE, CHAR(1);
DEFINE a1 CHAR(11);
DEFINE b1 CHAR(20);
DEFINE c1 CHAR(15);
DEFINE d1 DATE;
DEFINE e1 CHAR(1);
FOREACH entry FOR SELECT ssn5, last_name5, first_name5, birthdate5, sex5
INTO
a1,b1,c1,d1,e1 FROM 'edaqa'.NF29005
RETURN a1,b1,c1,d1,e1 WITH RESUME;
CONTINUE FOREACH;
END FOREACH
END PROCEDURE;
```

The following syntax is used to call the above stored procedure:

```
SQL SQLINF
EX SAMPLE;
TABLE ON TABLE PCHOLD
END
```

Chapter 41

Using the Adapter for Ingres

The Adapter for Ingres allows applications to access Ingres data sources. The adapter converts application requests into Ingres calls and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the Ingres Environment

In order to use the Adapter for Ingres, you must install the Ingres JDBC Driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the Ingres JDBC Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and check the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server EDAPRINT log. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for Ingres

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a Ingres data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf), if supported on your platform.

You can declare connections to more than one Ingres data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Ingres

The *Ingres* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the Ingres data source. It uses the following syntax:

```
jdbc:ingres://lnxx64r6:21071/qatst;TZ=GMT-5;DATE=INGRESDATE
```

where:

`TZ`

Specifies the Ingres time zone associated with the client's location. It corresponds to the Ingres environment variable II_TIMEZONE_NAME and is assigned the same value. This property is not used directly by the driver, but is sent to the DBMS and affects the processing of dates.

DATE

Specifies the data type of the columns created using the alias keyword *date*. Valid values are: *ansidate* or *ingresdate*. The default value is *ansidate* if the *send_ingres_dates* property is set to false, otherwise it is *ingresdate*. This value is not used directly by the driver, but is sent to the DBMS and affects the processing of query text.

Driver name

Name for the Ingres JDBC driver.

For example: com.ingres.jdbc.IngresDriver

See Ingres documentation for the specific driver release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLING SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

`SQLING`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection name.

`URL`

Is the URL to the location of the Ingres data source.

`userid`

Is the primary authorization ID by which you are known to the target database.

`password`

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the Ingres JDBC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMS will encrypt the password before adding it to the server profile.

Note: Consult vendor documentation for the exact name, port, and path.

```
ENGINE SQLING SET CONNECTION_ATTRIBUTES CON1
  'jdbc:ingres://lnxx64r6:21071/qatst;DATE=INGRESDATE;TZ=GMT-5'/uid,pwd
```

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLING SET DEFAULT_CONNECTION connection
```

where:

`SQLING`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLING SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLING SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

SQLING

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN

Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Ingres Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLING to identify the Adapter for Ingres.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLING [,$]
```

where:

file

Is the file name for the Master File. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLING

Is the value for the adapter.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server's metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Ingres

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.
- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Ingres Data Type Support* on page 1151.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Ingres synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLING ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Ingres table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Range is 0 to 64. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Ingres Data Type Support

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the Ingres Environment

The Adapter for Ingres provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to Ingres.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLING SET TIMEOUT {nn|0}
```

where:

`SQLING`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLING SET PASSRECS {ON|OFF}
```

where:

`SQLING`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Ingres Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 42

Using the Adapter for Interplex

The Adapter for Interplex allows applications to access Interplex data sources. The adapter converts application requests into native Interplex statements and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the Interplex Environment

Prior to configuring the Adapter for Interplex, the following must be installed:

- A middleware product on the Unisys platform.
- An ODBC driver on UNIX or Microsoft Windows/NT.

Configuring the Adapter for Interplex

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to the Interplex database server, the adapter requires connection and authentication information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

You can declare connections to more than one Interplex database server by including multiple SET CONNECTION_ATTRIBUTES commands. The actual connection to the Interplex Server takes place when the first query that references the connection is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Interplex

The *Interplex* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Datasource

The data source name (DSN). There is no default data source name. You must enter a value.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLIPX SET CONNECTION_ATTRIBUTES connection
DSN_name/userid,password
```

where:

`SQLIPX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the logical name used to identify this particular set of connection attributes.

Note that one blank space is required between *connection* and DSN_*name*.

`DSN_`*`name`*

Is the Interplex Data Source Name (DSN) you wish to access. It must match an entry in the odbc.ini file.

`userid`

Is the primary authorization ID by which you are known to Interplex.

`password`

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command declares connection CON1 to the Interplex DSN named SAMPLESERVER with an explicit user ID (MYUSER) and password (PASS). To ensure security, specify connection attributes from the Web Console, which encrypts the password before adding it to the server profile.

```
ENGINE SQLIPX SET CONNECTION_ATTRIBUTES CON1 SAMPLESERVER/MYUSER,PASS
```

Reference: Updating the Connection String

The syntax for the CONNECTION_ATTRIBUTES command for this adapter has been enhanced to include a logical connection name that is designed to support the porting of applications from development to production environments. This enhanced syntax may necessitate the migration of existing CONNECTION_ATTRIBUTES commands.

The Web Console's Migrate option migrates your server settings to the newer release. To access this option, select *Workspace*, then *Configuration/Monitor* from the menu bar. Right-click *Migrate* from the *Server* folder in the navigation pane, and select *Configure*. On the Migrate pane, type the full path of the configuration instance directory (EDACONF) and click the *Migrate* button. This is the recommended approach.

If you choose *not* to use the Migrate option, please note the following information:

- Connection names declared prior to Version 7 Release 6.1 are supported.
- If you create a new connection for the purpose of creating new synonyms, your existing connections are re-saved in a new format, and the existing synonyms continue to work without any changes.
- If you add a new connection for the purpose of using an existing synonym, you must change the default logical connection name to match the value that is stored in the existing Access File attribute CONNECTION=*value*.

  For example, suppose that prior 7.6.1 the connection was defined as:

  ```
  ENGINE SQLIPX SET CONNECTION_ATTRIBUTES DSN_A/uid,pwd
  ```

  When synonyms based on objects stored in this DSN_A are created, the Access Files contains the following description:

  ```
  CONNECTION=DSN_A
  ```

  If you then add a new connection, you must change the connection name from the default CON01 to DSN_A and save it as DSN_A in order to reuse the existing synonym. The connection is stored in the profile as:

  ```
  ENGINE SQLIPX SET CONNECTION_ATTRIBUTES DSN_A DSN_A/uid,pwd
  ```

Overriding the Default Connection

Once connections have been defined, the connection named in the first SET CONNECTION_ATTRIBUTES command serves as the default connection. You can override this default using the SET DEFAULT_CONNECTION command.

Syntax: How to Change the Default Connection

```
ENGINE SQLIPX SET DEFAULT_CONNECTION connection
```

where:

SQLIPX

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLIPX SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLIPX SET AUTODISCONNECT ON {FIN|COMMAND|COMMIT}
```

where:

SQLIPX

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

FIN

Disconnects automatically only after the session has been terminated. FIN is the default value.

COMMAND

Disconnects automatically after each request. Depending on how often the event occurs, the SET AUTODISCONNECT command may result in considerable overhead. Almost all of this overhead is not related to the server. It is related to the operating system and the data source.

COMMIT

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing Interplex Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Interplex data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Interplex table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.

- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Interplex

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for Interplex synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Generated Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLIPX ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4,    I9,  I4,  MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION_NA4, A25, A25, MISSING=ON  ,$
FIELD=DIVISION_HE4, DIVISION_HE4, I9,  I4,  MISSING=ON  ,$
```

Generated Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=DSN_A,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the Interplex table. The value assigned to this attribute can include the name of the owner (also known as schema). and the database link name as follows: TABLENAME=[*owner*.]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local database server. Absence of the CONNECTION attribute indicates access to the default database server.
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support

Data types are specific to the underlying data source.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the Interplex Environment

The Adapter for Interplex provides several parameters for customizing the environment and optimizing performance.

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: **How to Obtain the Number of Rows Updated or Deleted**

```
ENGINE SQLIPX SET PASSRECS {ON|OFF}
```

where:

`SQLIPX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

Interplex Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 43

Using the Adapter for iWay Adapter Framework (IWAF)

The Adapter for iWay Adapter Framework allows application to access IWAF enabled data sources.

In this chapter:

Preparing the IWAF Environment

The IWAF adapter has the following requirements:

- **Java:** To use these Java-based adapters, you must have a Java Virtual Machine (JVM) installed and in the path on the server. The JVM can be downloaded from *http://www.java.com.*

  On a Windows server, the JVM location must be added to the PATH. For example:

  ```
  C:\Program Files\Java\jre6\bin\client;C:\Program Files\Java\jre6\bin;
  ```

- **Connectors:** The iWay Connector jar files must be obtained from Information Builders. Please contact Information Builders Technical Support to obtain these files.

- **Adapter files:** These are the jar files for any applications being accessed and are obtained from the application vendor.

  Note: The location of the jar files should be specified in the IWAF_HOME environmental variable.

Procedure: How to Configure the IWAF_HOME Environmental Variable

1. From the Workspace menu, select *Configuration/Monitor*.

   or

   From the Data Management Console, open the *Workspace* and *Configuration/Monitor* folders.

2. On the navigation tree, open the *Configuration Files* and *Miscellaneous* folders.

3. From the *Miscellaneous* folder, right-click *Environment – edaenv.cfg* and select *Edit*.

   The Edit Environment Configuration page opens, showing the location of the file in the window title.

4. Enter the location of the iWay connector and application jar files. For example, if you had placed those files in the c:\ibi\iwaf directory, you would enter:

   ```
   IWAF_HOME=c:\ibi\iwaf
   ```

5. Click the *Save* button to save the file.
6. Stop and restart the server.

Configuring the Adapter for IWAF

Configuring the adapter consist of specifying connection and authentication information for each of the connections you want to establish.

Note: You can declare connection attributes for an adapter that will allow you to create synonyms for either a service or an event.

Procedure: How to Configure the IWAF Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Click *OK* to allow changes to the server configuration.

   The IWAF Successfully added to configuration window appears.

6. Click *Restart Java Services* and then click *OK*.

Procedure: How to Declare Connection Attributes for an IWAF Adapter

You can declare connection attributes for an IWAF adapter from either the Web Console or the Data Management Console.

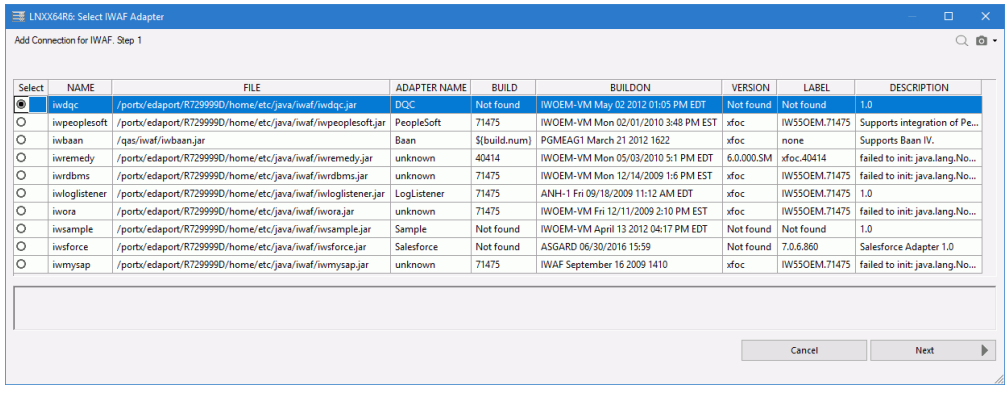
1. From the Web Console menu bar, click *Adapters*

   or

   From the Data Management Console, expand the *Adapters* folder.

   The Adapters folder opens.
2. Expand the *Available* folder, if it is not already expanded.
3. Expand the *Configured* folder, right-click *IWAF*, and select *Add Adapter*.
4. From the list of IWAF adapters, check the radio button for the one you want and click *Next*.

   This list of IWAF adapters will vary from the illustration below depending on what has been installed on your server.



Select	NAME	FILE	ADAPTER NAME	BUILD	BUILDON	VERSION	LABEL	DESCRIPTION

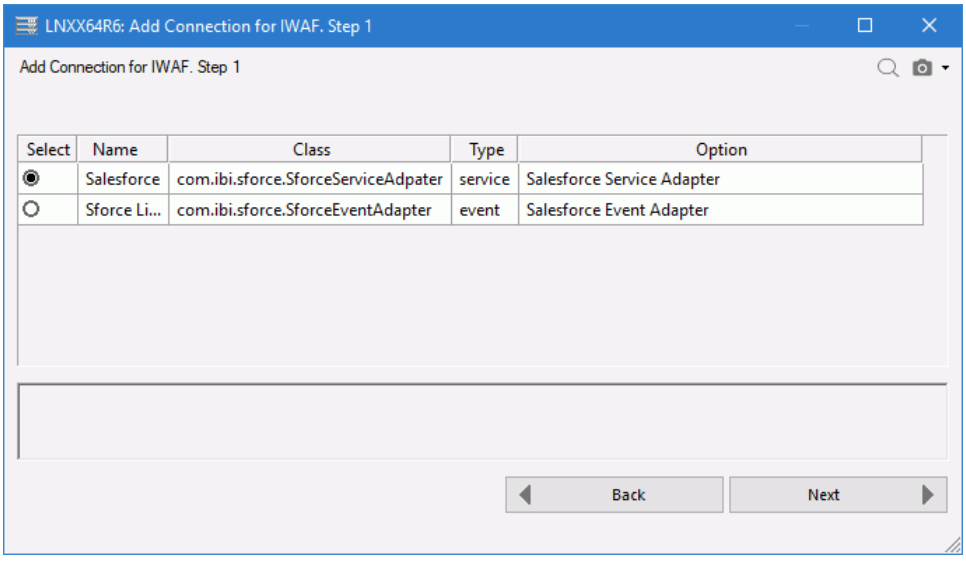
   For an explanation of the information in the adapters list, see *IWAF Adapter Information* on page 1174.
5. Select the connection type and click *Next*.

The following image shows the dialog box for Salesforce.com with the Salesforce Service Adapter selected (*service* type). The parameters required will depend on whether you select a *service* or *event* adapter.

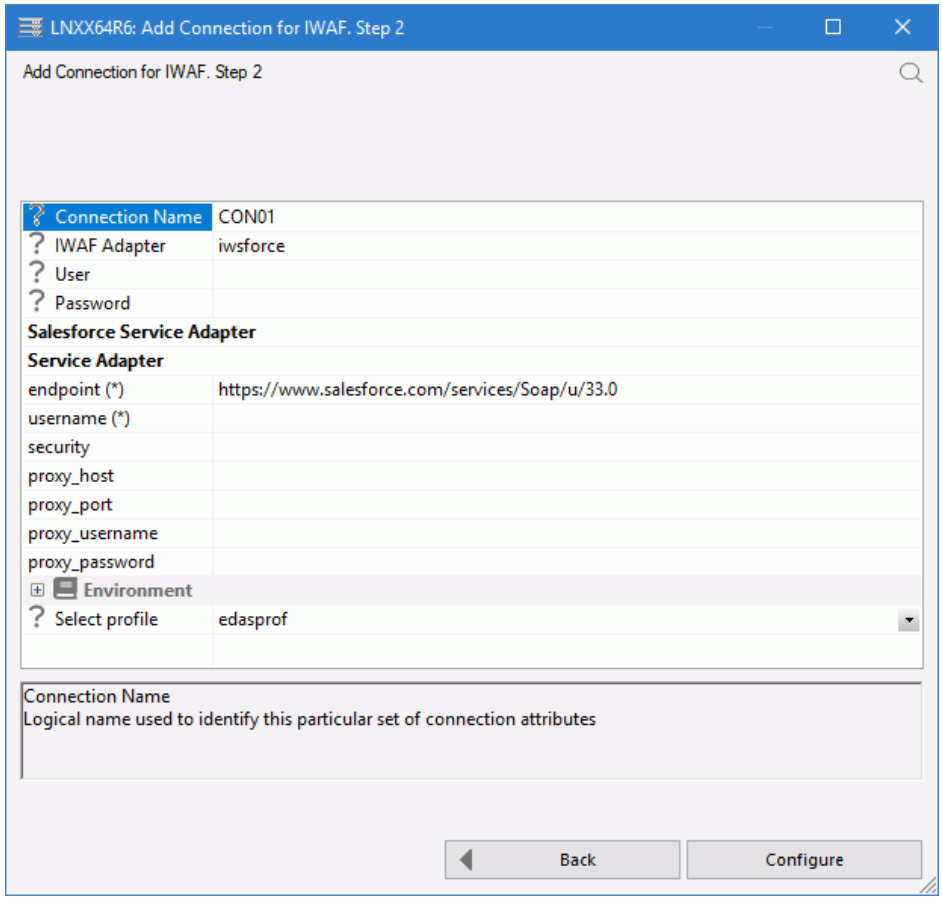


For an explanation of the information in the adapters list, see *IWAF Connection* on page 1175.

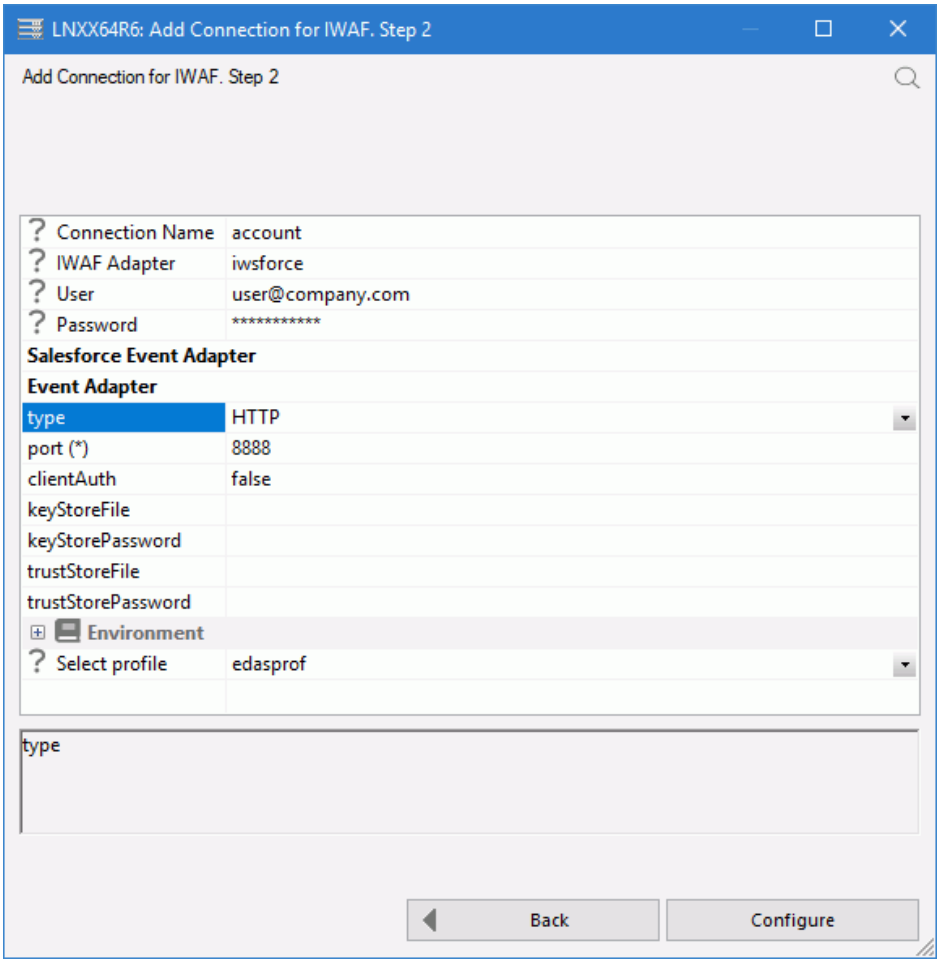
6. Enter values for the parameters required by the adapter and click *Configure*.

   For a description of these parameters, see *IWAF Connection Parameters* on page 1175.

The following illustration shows sample connection parameters for a Salesforce.com service adapter.



The following illustration shows sample connection parameters for a Salesforce.com event adapter.



Reference: IWAF Adapter Information

The following list describes the information in Select IWAF Adapter dialog box.

Name

Internal name of the Adapter.

File

Full path and location of the jar file for this adapter.

Adapter Name

Name of the adapter as it will appear in the Metadata tree.

Build

iWay build number.

Build on

Date and time the adapter was built.

Version

iWay internal build number.

Label

iWay Subversion number.

Description

Adapter description.

Reference: IWAF Connection

The following list describes the information in the Select IWAF Adapter dialog box.

Name

Name of the IWAF adapter.

Class

Name of the class file.

Type

Name of the Java class.

Option

Description of the adapter type.

Reference: IWAF Connection Parameters

The following list describes the information in the Add Connection to IWAF dialog box. Not all options appear for all applications.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

iWAF Adapter

Name of the IWAF adapter.

username (UserName)

User name for this connection.

security (Security Token)

The value provided by salesforce.com.

type (Listener Type)

HTTP or HTTPS.

User

Authorization ID to connect to the source.

Port (listener port)

The port number that will listen for SOAP messages from the application.

Password

Password associated with the authorization ID.

Adapter Specific

Additional options depending on the adapter selected.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Creating Synonyms With iWay Adapter Framework (IWAF)

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note: If you are creating a synonym for a SQLBase data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

Procedure: How to Create a Synonym for a Service

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Procedure: How to Create a Synonym for an Event

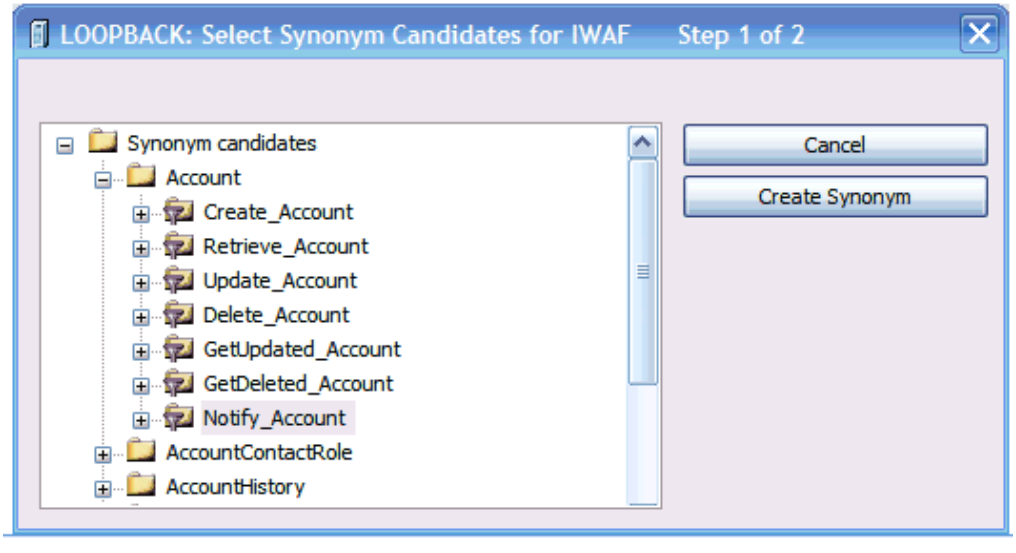
To create a synonym for an event, you must have previously configured the adapter for both the general service and a specific event. You can create a synonym from the Applications or Adapters pages of the Web Console.

1. From the Web Console *Applications* page, click *Get Data*.
2. Click the *New* button and select *Synonym* from the drop-down menu.

   The Select adapter to configure or Select connection to create synonym pane opens.
3. Click a connection to the configured adapter.

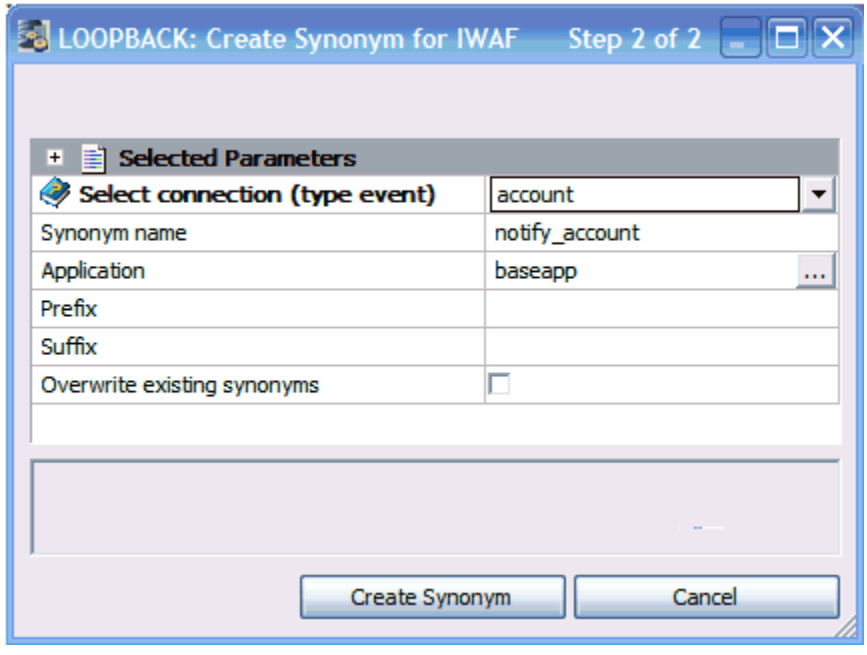
   Note: Even though you are creating a synonym for an event, you must select the associated service to create a synonym.

   The select synonym candidate for IWAF screen opens.
4. Expand a folder, select an event, and click *Create Synonym*. The following image shows the selection of *Notify_Account* from the *Account* folder.



The Create synonym for IWAF screen opens.

5. From the *Select connection (type event)* drop-down menu, select the connection for the event, in this example account.



6. Click *Create Synonym*.

The Status pane indicates that the synonym was created successfully.

Chapter 44 Using the Adapter for JBoss Application Server

The Adapter for JBoss Application Server allows applications to access JBoss data sources. The adapter converts application requests into JBoss calls and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the JBoss Application Server Environment

In order to use the Adapter for JBoss Application Server, you must install the JBoss driver, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the JBoss Teiid JDBC driver JAR files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for Teiid JDBC Driver files:

   ```
   CLASSPATH=/usr/jboss/teiid-client.jar:/usr/jboss/teiid-hibernate
   -dialect-7.4.1.jar:$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=C:\jboss-soa-p-5\*\teiid-client.jar;C:\jboss-soa-p-5\*\teiid-
   hibernate-dialect-7.4.1.jar;%CLASSPATH%
   ```

   See JBoss Application Server documentation for specific file names and their locations.

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and check the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server's EDAPRINT. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for JBoss Application Server

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a JBoss data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one JBoss data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for JBoss Application Server

The JBoss Application Server adapter in under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the JBoss data source.

Driver name

Name for the JBoss Teiid JDBC driver.

For example: org.teiid.jdbc.TeiidDrive

See JBoss Application Server documentation for the specific driver release you are using.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLMMX SET CONNECTION_ATTRIBUTES connection 'URL'/userid,password
```

where:

`SQLMMX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection name.

`URL`

Is the URL to the location of the JBoss data source.

userid

Is the primary authorization ID by which you are known to the target database.

password

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to a data source using the JBoss Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

Note: Consult vendor documentation for the exact name, port, and path.

```
ENGINE SQLMMX SET CONNECTION_ATTRIBUTES CON1
  'jdbc:jboss:Tmix_Vdb@mm://hostname:31000'
```

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLMMX SET DEFAULT_CONNECTION connection
```

where:

SQLMMX

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

```
FOC1671, Command out of sequence.
```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLMMX SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLMMX SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

`SQLMMX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing JBoss Application Server Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLMMX to identify the Adapter for JBoss Application Server.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLMMX [,$]
```

where:

file

Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLMMX

Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using the JBoss Application Server, you must locally install the RDBMS JBoss Driver.

The Server can access third-party database tables across the JBoss Application Server network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server global profile or in a user profile.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note: If you are creating a synonym for a JBoss data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for JBoss Application Server

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support* on page 1194.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for JBoss Application Server synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLMMX ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the JBoss table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support

Data types are specific to the underlying data source.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the JBoss Application Server Environment

The Adapter for JBoss Application Server provides several parameters for customizing the environment and optimizing performance.

Specifying a Payload to Pass to JBoss Application Server

PAYLOAD specifies a JBoss Application Server trusted payload as one or more comma-delimited pairs (represented as '*Key*','*Value*') that you can pass to the JBoss Application Server.

Syntax: How to Specify a Payload to Pass to the JBoss Application Server

```
ENGINE SQLMMX SET PAYLOAD
'KEY1','VALUE1','KEY2','VALUE2',...,'KEYn','VALUEn'
```

Note: Payload can be any 'KEY','VALUE' pair that the JBoss Application Server accepts. There is no limit to the number of pairs that can be sent.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to the JBoss Application Server.

Syntax: How to Issue the TIMEOUT Command

```
ENGINE SQLMMX SET TIMEOUT {nn|0}
```

where:

`SQLMMX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a time-out occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLMMX SET PASSRECS {ON|OFF}
```

where:

`SQLMMX`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

ON

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

OFF

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

JBoss Application Server Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 45

Using the Adapter for JDBC

The Adapter for JDBC allows applications to access specific JDBC data sources. The adapter converts application requests into JDBC calls and returns optimized answer sets to the requesting application.

For details about JDBC-supported data sources, see the *Server Release Notes*.

In this chapter:

Preparing the JDBC Environment

In order to use the Adapter for JDBC, you must install the JDBC driver for whichever data source you would like to access, set its CLASSPATH value before server startup, and ensure that the JSCOM3 service is running.

For example, if you want to access a UniData database, you must install a JDBC driver for UniData. You can configure only one generic JDBC adapter per server instance.

Note:

- If Information Builders offers an adapter for a specific data source type, you should use that adapter to access that type. The Adapter for JDBC does not support data source types for which a specific adapter already exists. For example, Information Builders provides the Adapter for Db2 to access Db2 databases, so you should not use the Adapter for JDBC to access Db2.

- If Information Builders does not currently offer a specific adapter for a data source type, you may use the Adapter for JDBC with a vendor-provided JDBC driver. Note that the adapter conforms to generic JDBC standards. Vendors, on the other hand, may have interpreted or extended those standards for their specific data source requirements. If this introduces an incompatibility, you may experience inconsistent behavior when using the adapter for that vendor's data source type. If this occurs please contact Customer Support Services for assistance. Information Builders will work with your enterprise to try and support your data access needs.

Procedure: How to Set Up the Environment on Windows and UNIX

1. Identify the location of the JDBC Driver files by adding them to the environment variable CLASSPATH before server startup.

   For example, to set a UNIX or IBM i location for some JDBC Driver files to /usr/driver_files/mydriver.jar, issue the commands:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   Similarly, on Windows, you would issue the command:

   ```
   set CLASSPATH=c:\usr\driver_files\mydriver.jar:%CLASSPATH%
   ```

   Note that if you run the server workspace as a Windows service, you must set the CLASSPATH as a system-wide environment variable.

   Similarly, on UNIX, to ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

2. Start (or restart) the server.

   (Note that you also need to restart the server if the driver has changed.)

3. Verify that the JSCOM3 service is active by issuing the following command in the server workspace

   ```
   edastart -show
   ```

   and checking that the special services section displays "JSCOM3 active".

   If the JSCOM3 service is not active, a "fail to start" message will typically also be in the server EDAPRINT log. To resolve the problem, review the JDBC listener requirements in the chapter for your operating system in the *Server Installation* manual.

Configuring the Adapter for JDBC

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to a JDBC data source, the adapter requires connection and authentication information.

You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration pane. The consoles add the command to the server profile you select: global (edasprof.prf), user (user.prf), or group (group.prf) if supported on your platform.

You can declare connections to more than one JDBC data source using the SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query is issued. If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.
- If more than one SET CONNECTION_ATTRIBUTES command contains the same connection name, the adapter uses the attributes specified in the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for JDBC

The *JDBC* adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Location URL for the JDBC data source.

Driver name

Name for the JDBC driver.

See driver documentation for the specific release you are using.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.

- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE SQLJDBC SET CONNECTION_ATTRIBUTES connection
'URL'/userid,password
```

where:

`SQLJDBC`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection name.

`URL`

Is the URL to the location of the JDBC data source.

`userid`

Is the primary authorization ID by which you are known to the target database.

`password`

Is the password associated with the primary authorization ID.

Example: Declaring Connection Attributes

The following SET CONNECTION_ATTRIBUTES command connects to data source using the JDBC Driver, with an explicit user ID (MYUSER) and password (PASS). To ensure security, specifying connection attributes from the Web Console or DMC will encrypt the password before adding it to the server profile.

```
ENGINE SQLJDBC SET CONNECTION_ATTRIBUTES CON1
  'jdbc:xxxxxxx://hostname:port/datasource
```

Overriding the Default Connection

If multiple connections have been defined, the connection named in the *first* SET CONNECTION_ATTRIBUTES command serves as the default connection.

Syntax: How to Change the Default Connection

```
ENGINE SQLJDBC SET DEFAULT_CONNECTION connection
```

where:

`SQLJDBC`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

Is the connection defined in a previously issued SET CONNECTION_ATTRIBUTES command. If this name was not previously declared, the following message is issued:

```
FOC1671, Command out of sequence
```

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the *last* command serves as the default connection.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, the following message is issued:

  ```
  FOC1671, Command out of sequence.
  ```

Example: Selecting the Default Connection

The following SET DEFAULT_CONNECTION command selects the database server named SAMPLE as the default database server:

```
ENGINE SQLJDBC SET DEFAULT_CONNECTION SAMPLE
```

Controlling the Connection Scope

The SET AUTODISCONNECT command controls the persistence of connections when using the adapter for each of the connections you want to establish.

Syntax: How to Control the Connection Scope

```
ENGINE SQLJDBC SET AUTODISCONNECT ON {FIN|COMMIT}
```

where:

`SQLJDBC`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`FIN`

Disconnects automatically only after the session has been terminated. FIN is the default value.

`COMMIT`

Disconnects automatically only after COMMIT or ROLLBACK is issued as a native SQL command.

Managing JDBC Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each object the server will access, you create a synonym that describes its structure and the server mapping of the data types.

Identifying the Adapter

The SUFFIX attribute in the Master File identifies the adapter needed to interpret a request. Use the SUFFIX value SQLJDBC to identify the Adapter for JDBC.

Syntax: How to Identify the Adapter

```
FILE[NAME]=file, SUFFIX=SQLJDBC [,$]
```

where:

file

Is the file name for the Master File. The file name without the .mas extension can consist of a maximum of eight alphanumeric characters. The file name should start with a letter and be representative of the table or view contents. The actual file must have a .mas extension, but the value for this attribute should not include the extension.

SQLJDBC

Is the value for the adapter.

Accessing Database Tables

If you choose to access a remote third-party table using JDBC, you must locally install the RDBMS' JDBC Driver.

The Server can access third-party database tables across the JDBC network. You must specify a URL for the data source and, possibly, a user ID and/or password for the database you are accessing. You can define these parameters in either the server's global profile or in a user profile.

Creating Synonyms

Synonyms define unique names (or aliases) for each object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

Note: If you are creating a synonym for a JDBC data source, you must first add the syntax SET SYNONYM=BASIC to the edasprof.prf file.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for JDBC

The following list describes the synonym creation parameters for which you can supply values.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Filter by Owner/Schema and Object name

Selecting this option adds the Owner/Schema and Object Name parameters to the screen.

- **Owner/Schema.** Type a string for filtering the selection, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner/schema begin with the letters ABC; %ABC to select tables or views whose owner/schema end with the letters ABC; %ABC% to select tables or views whose owner/schema contain the letters ABC at the beginning, middle, or end.

- **Object name.** Type a string for filtering the object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Location of External SQL Scripts

If you specify *External SQL Scripts* in the *Restrict Object type to* field, these additional fields are displayed.

The following standard naming conventions apply for UNIX, IBM i IFS, and z/OS HFS:

- In the *Base Location* field, specify the physical directory location of the file that contains the SQL Query. You can type a directory name or click on the ellipsis. This opens the Select Base Location dialog box.

- In the *Document Name* field, enter the file name with or without wild card characters.

- In the *Document Extension* field, enter the extension of the script files to filter the list of candidates.

On IBM i, you can use alternative IFS naming conventions to access library members. The following entry illustrates this method:

- In the *Base Location* field, enter:

  `/QSYS.LIB/MYLIBRARY.LIB/MYSRC.FILE`

- The *Document Extension* is understood to be MBR. You can enter this value explicitly or leave the input box blank.

During synonym generation, the adapter issues native API calls to obtain a list of elements in the select list and builds the Master File with a field for each element. The generated Access File references the location of the SQL script in the DATASET attribute, which contains the full path, including the name and extension of the file containing the SQL Query. For example,

```
DATASET=/ul/home2/apps/report3.sql
```

When a WebFOCUS report is created, the SQL Query is used to access data.

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

For information about customizable mappings, see *Data Type Support Report* on page 1211.

Update or Create Metadata

Select *Create* to overwrite any existing synonym with the same fully-qualified name, or *Update* to synchronize the metadata with an existing synonym. If you select *Update*, the next screen will show a list of attributes from the DBMS catalog that you can check to allow attributes from the DBMS catalog to override attributes from the existing synonym.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Owner/Schema

The user account that created the object or a collection of objects owned by a user.

Table name

Is the name of the underlying object.

Type

The object type (Table, View, and so on).

Select tables

Select tables for which you wish to create synonyms:

- To select all tables in the list, select the *Select All* check box.
- To select specific tables, select the corresponding check boxes.

Example: Sample Generated Synonym

An Adapter for JDBC synonym comprises a Master File and an Access File. This is a synonym for the table nf29004.

Master File nf29004.mas

```
FILE=DIVISION, SUFFIX=SQLJDBC ,$
SEGNAME=SEG1_4, SEGTYPE=S0 ,$
FIELD=DIVISION4,    DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_NA4, DIVISION4, I9, I4, MISSING=OFF ,$
FIELD=DIVISION_HE4, DIVISION4, I9, I4, MISSING=OFF ,$
```

Access File nf29004.acx

```
SEGNAME=SEG1_4,TABLENAME=EDAQA.NF29004,
CONNECTION=CON1,KEYS=1,WRITE=YES,$
```

Reference: Access File Keywords

This chart describes the keywords in the Access File.

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.
TABLENAME	Identifies the JDBC table. The value assigned to this attribute can include the name of the owner (also known as schema) and the database link name as follows: TABLENAME=[*owner.*]*table*
CONNECTION	Indicates a previously declared connection. The syntax is: CONNECTION=*connection* CONNECTION=' ' indicates access to the local data source. Absence of the CONNECTION attribute indicates access to the default database server.

Keyword	Description
KEYS	Indicates how many columns constitute the primary key for the table. Corresponds to the first *n* fields in the Master File segment. See the KEY attribute below for information about specifying the key fields without having to describe them first in the Master File.
KEY	Specifies the columns that participate in the primary key without having to describe them as the first fields in the Master File. The syntax is: KEY=*fld1/fld2/.../fldn*
WRITE	Specifies whether write operations are allowed against the table.
KEYFLD IXFLD	Supply the names of the primary key and foreign key fields that implement the relationships established by the multi-table Master File. Together, KEYFLD and IXFLD identify the field shared by a related table pair. ❑ KEYFLD is the FIELDNAME of the common column from the parent table. ❑ IXFLD is the FIELDNAME of the common column from the related table. KEYFLD and IXFLD must have the same data type. It is recommended, but not required, that their lengths also be the same. **Note:** An RDBMS index on both the KEYFLD and IXFLD columns provides the RDBMS with a greater opportunity to produce efficient joins. The columns must have the same data type. If their length is the same, the RDBMS handles the join more efficiently.

Reference: **Managing Synonyms**

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Data Type Support Report

SQL Data Type mapping options are available in a report available from the Web Console.

For more information, see *How to Access the Data Type Report* on page 95.

Changing the Precision and Scale of Numeric Columns

You can alter the length and scale of numeric columns returned by a SELECT request to the server by creating different specifications in your login profile or in a stored procedure. The conversion settings are reflected in the Master File in the USAGE and ACTUAL formats of the fields generated by CREATE SYNONYM. This affects how the fields are processed and formatted by the server.

Tip: You can change this setting manually or from the Web Console.

For more information, see *How to Override the Default Precision and Scale* on page 96.

Customizing the JDBC Environment

The Adapter for JDBC provides several parameters for customizing the environment and optimizing performance.

Specifying a Timeout Limit

TIMEOUT specifies the number of seconds the adapter will wait for a response after you issue an SQL request to JDBC.

Syntax: **How to Issue the TIMEOUT Command**

```
ENGINE SQLJDBC SET TIMEOUT {nn|0}
```

where:

`SQLJDBC`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

nn

Is the number of seconds before a timeout occurs. 30 is the default value.

`0`

Represents an infinite period to wait for a response.

Cancelling Long Requests

You can cancel long running requests from the Web Console. Depending on the capabilities of the native JDBC driver, this action will either cancel the request entirely or break out of the fetch cycle.

Procedure: How to Cancel Long Requests

1. From the Web Console menu bar choose *Workspace*, *Configuration/Monitor*, *Java Services*, DEFAULT. Right-click on *DEFAULT* and select *Agents*.
2. In the Java Services Agents pane, highlight a row with the jscomid you wish to kill, right-click on it and select *Stop.*

Obtaining the Number of Rows Updated or Deleted

PASSRECS returns the number of rows affected by a successfully executed SQL Passthru INSERT, UPDATE, or DELETE command.

Tip: You can change this setting manually or from the Web Console by clicking *Data Adapters* on the menu bar, clicking a configured adapter, and choosing *Change Settings* from the menu. The Change Settings pane opens.

Syntax: How to Obtain the Number of Rows Updated or Deleted

```
ENGINE SQLJDBC SET PASSRECS {ON|OFF}
```

where:

`SQLJDBC`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`ON`

Provides the number of rows affected in the application program SCB count member after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command. ON is the default value.

`OFF`

Provides no information after the successful execution of an SQL Passthru INSERT, UPDATE, or DELETE command.

JDBC Optimization Settings

Adapter optimization allows the RDBMS to perform the work for which it is best suited, reducing the volume of RDBMS-to-server communication and improving response time. It also enables the RDBMS to exploit its own internal optimization techniques.

For more information, see *Optimizing Requests* on page 109.

Chapter 46 Using the Adapter for JD Edwards EnterpriseOne

The Adapter for JD Edwards EnterpriseOne allows WebFOCUS and other applications to access JD Edwards EnterpriseOne data sources. With this adapter, data in the JD Edwards EnterpriseOne DBMS is displayed using rules contained in dictionary files, thereby ensuring that valid information is returned to the requesting program.

This adapter is available for the Windows and IBM i environments. It is intended for use with WebFOCUS Version 7 Release 7 and higher.

In this chapter:

Preparing the JD Edwards EnterpriseOne Environment

Although no environment preparation steps are required, ensure that your system complies with all software specifications.

You must also disable Automatic Passthru to ensure proper processing of JD Edwards EnterpriseOne data.

Reference: Software Requirements

- Any JD Edwards EnterpriseOne Application installation.
- DBMS connectivity, as required by the installed EnterpriseOne environment. The following DBMSs are currently supported:
  - Oracle

- Microsoft SQL Server
- DB2

Note: This adapter can only be configured with reporting servers on the Windows and IBM i operating systems.

Syntax: How to Disable Automatic Passthru

To turn Automatic Passthru off, enter the following command in the server profile, edasprof.prf:

```
SQL
   SET APT = OFF;
END
```

Overview of the Setup Process

The setup process for the Adapter for EnterpriseOne is comprised of the following basic steps:

1. **Create the JD Edwards EnterpriseOne synonyms.** You use the synonym creation facility for Db2, Microsoft SQL Server, or Oracle.

   Note: For IBM i, see *How to Create Synonyms for JD Edwards EnterpriseOne Under IBM i* on page 1219
2. **Configure the Adapter for JD Edwards EnterpriseOne.** This indicates whether you will be using Group-based or Role-based security.
3. **Refresh security extracts.** You will need to perform this step initially, and repeat it only if security information changes.
4. **Refresh the metadata repository.** You will need to perform this step initially, and repeat it only if there are changes in the metadata for tables. This occurs infrequently at most sites.
5. **Convert the synonyms for JD Edwards EnterpriseOne.**
6. **Set UDCDIC parameters (Windows only).** This step is required before you can run reports.

Configuring the Adapter for JD Edwards EnterpriseOne

This process defines connection and authentication information.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Configuration Parameters and Tasks for JD Edwards EnterpriseOne

The *JD Edwards EnterpriseOne* adapter is under the *ERP* group folder.

The following list describes the connection attributes for which you can supply values, and additional tasks you must perform to complete the configuration for this adapter.

Security Authentication

- Check this box if the reporting server is secured. This option applies if every JD Edwards EnterpriseOne user has a user ID on the reporting server system.
- Leave the box unchecked if the reporting server is unsecured. This option applies if every JD Edwards EnterpriseOne user's user ID and password are stored and are being authenticated by Managed Reporting and/or a self-service application:
  - For Managed Reporting, the user ID must be the JD Edwards EnterpriseOne user ID.
  - For Self-Service requests, the JD Edwards EnterpriseOne user ID must be passed to the server.

  In either case, the IBI_REPORT_USER variable must be set to the JD Edwards EnterpriseOne user ID.

ROLE-based security

When you configure the JD Edwards EnterpriseOne adapter, Group-based security is used by default. Leave the box unchecked, if you wish to use Group-based security.

Check this box if you wish to use Role-based security.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

When you click the *Configure*, the adapter is added to the Adapters list in the Web Console or the Adapters folder of the Data Management Console.

Creating Synonyms for JD Edwards EnterpriseOne

Before you can use the Adapter for JD Edwards EnterpriseOne, you must create synonyms for the data you will be reporting against using one of the data adapters that is supported on your platform, and set the paths required to access those synonyms:

- In the Windows environment, you can create synonyms using the Adapters for Db2, Oracle, or Microsoft SQL Server.
- In the IBM i environment, you can create synonyms using Db2.

Procedure: How to Create Synonyms for JD Edwards EnterpriseOne

Note: To create a synonym under IBM i, see *How to Create Synonyms for JD Edwards EnterpriseOne Under IBM i* on page 1219

From the Web Console or the Data Management Console:

1. Configure the adapter you wish to use to create synonyms for the JD Edwards EnterpriseOne data.
2. Use the configured adapter to create synonyms for the JD Edwards EnterpriseOne tables you wish to use. During this process, you will select the tables for which you wish to create synonyms and specify the application in which the tables will be stored.

For details about configuration and synonym creation steps for supported data adapters, see *Using the Adapter for Db2* on page 497, *Using the Adapter for Microsoft SQL Server* on page 1399, or *Using the Adapter for Oracle* on page 1769.

Procedure: How to Create Synonyms for JD Edwards EnterpriseOne Under IBM i

1. From the Web Console *Applications* page, click *Get Data*.
2. Double-click a Db2 connection.

   The first of a series of synonym creation panes opens.
3. Enter values for the parameters required by the adapter as described in *Synonym Creation Parameters for JD Edwards EnterpriseOne Under IBM i* on page 1219.
4. After entering the parameter values, click *Create Synonym*.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Reference: Synonym Creation Parameters for JD Edwards EnterpriseOne Under IBM i

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Select Synonym Candidates for Db2 (CON) Step 1

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Library

Type a string for filtering the Library (or Db2 Collection), inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner IDs begin with the letters ABC; %ABC to select tables or views whose owner IDs end with the letters ABC; %ABC% to select tables or views whose owner IDs contain the letters ABC at the beginning, middle, or end.

Object Name

Type a string for filtering the table, view, or object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all tables, views, or objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Note: When you create a synonym for Db2 on the IBM i platform, standard IBM i naming conventions apply to the target data source. Therefore, the Adapter for Db2 supports the use of double-quotation marks around any library name and/or file name that contains lowercase or NLS characters.

Create Synonym for Db2 (CON) Step 2 of 3

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

One-part name

On the IBM i platform, the *One-part name* check box is unchecked by default. The unchecked behavior generates a table name that includes the explicit name of the library containing the table. For example, if you specified a library on the first Create Synonym pane, a qualified name like the following is automatically created in the Access File:

```
TABLENAME=MYLIB/MYTABLE
```

With this explicit type of entry in the Access File, at run-time the library is directly located and searched for the table name. If you select the check box, the explicit library name is not stored in the metadata (Access File). When the synonym is generated, the library portion of the table name is omitted from the Access File, and appears as follows:

```
TABLENAME=MYTABLE
```

With this type of entry in the Access File, at run time the library path of the user is searched until the table name is located.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Create Synonym for Db2 Step 3 of 3

Select date format

The options are: YMD, YYMD, DMY, MDY, MDYY, DMYY, MYY,YYM. (YYMD is the default setting.) The selected format will be used only if the field is described as a DATE in the DataDictionary.

Presumptive Join

Select the *Presumptive Joins* check box to include additional DEFINEs (virtual fields) for presumptive join fields in the synonym.

The default setting is *ON*.

Field Names

Select the *Long Fieldname* radio button (the default) to display the field descriptions as names on reports. Select the *Short Fieldname* radio button to use the JDE aliases as field names on reports. The default setting is *Long Fieldname*.

Language Code

Enter the appropriate Language Code, which exists in the JDE F9292 file. (Leave the field blank for English.)

UDC

Select the *UDC* check box to ensure that UDC description fields are generated as DEFINEs (virtual fields) in the synonym. The default setting is *ON*.

Combine UDC

Select the *Combine UDC* check box to Combine User Defined Code. The default setting is *OFF*.

Reference: Ensuring Master File Compatibility Between IBM i and Windows

Before you begin the configuration procedure, it is advisable to consider whether you have procedures that were designed to run on the IBM i platform, which you may wish to run in a Windows environment. If you anticipate this need, your first task is to synchronize the Master Files generated on Windows with those generated on IBM i using the amper variable &MFDCOMP in the jdegdinc.fex file.

The default variable setting is:

```
-DEFAULT &MFDCOMP='N';
```

To ensure matching field names on IBM i and Windows, revise the setting to:

```
-DEFAULT &MFDCOMP='Y';
```

Refreshing the Metadata Repository

The Metadata repository contains the dictionary information for the JD Edwards EnterpriseOne tables.

You must refresh the repository the first time you set up the adapter and repeat the process each time the JD Edwards EnterpriseOne tables change. (At most sites, changes occur infrequently.)

Important: This step must be done before you convert any Master Files (synonyms).

Procedure: How to Refresh the Metadata Repository on Windows

From the Adapters list in the navigation pane on the Web Console or the Adapters folder of the Data Management Console:

1. Right-click the configured JD Edwards EnterpriseOne adapter.
2. Choose *Refresh Metadata Repository* from the menu. The Refresh Metadata Repository pane opens. The JDE tables required for this procedure are listed in the first column.
3. For *each* table, select the suffix of a previously configured DBMS from the drop-down list.

   Note: The listed tables may be associated with different DBMSs.
4. In the Qualifier input boxes enter the qualifier associated with each table, using the syntax required for the selected DBMS:
   - For SQLMSS: `[database.]owner`
   - For Db2: `[location.]owner`
   - For SQLORA: `owner`
5. In the Connection input boxes, enter the same connection name you used when configuring the selected DBMS.
6. Click *Refresh Now*. The refresh occurs transparently. A message indicates the process was successful.

Procedure: How to Refresh the Metadata Repository on IBM i

From the Adapters list in the navigation pane on the Web Console or the Adapters folder of the Data Management Console:

1. Right-click the configured JD Edwards EnterpriseOne adapter and select *Refresh Metadata Repository*.

You will need to perform this step initially, and repeat it only if there are changes in the metadata for tables. This occurs infrequently at most sites.

The Refresh Metadata Repository pane opens. The JDE tables required for this procedure are listed in the first column.

2. For *each* table, select the suffix of a previously configured DBMS from the drop-down list.

   Note: The listed tables may be associated with different DBMSs.

3. Click *Refresh Now*.

Refresh Security Extracts

This process creates security extract files that are stored as FOCUS files in the JOWSEC application that is created when you configure the adapter.

You must repeat this step whenever security extract information needs to be updated.

Procedure: How to Refresh Security Extracts on Windows

From the Adapters list in the navigation pane or the Adapters folder of the DMC:

1. Right-click the configured JD Edwards EnterpriseOne adapter.
2. Select *Refresh Security Extracts*.

   The Refresh Security Extracts pane opens, indicating the Security mode you selected during adapter configuration: ROLE-based or GROUP-based (see *Configuration Parameters and Tasks for JD Edwards EnterpriseOne* on page 1217). Note that the required JDE tables that are listed in the first column vary depending on the Security mode that is in effect.

3. For each table, select the suffix of a previously configured DBMS from the drop-down list.

   Note: The listed tables may be associated with different DBMSs.

4. In the Qualifier input boxes enter the qualifier associated with each table, using the syntax required for the selected DBMS:

   - For SQLMSS: `[database.]owner`
   - For Db2: `[location.]owner`
   - For SQLORA: `owner`

5. In the Connection input boxes, enter the same connection name you used when configuring the selected DBMS.
6. Click *Submit*.

   The refresh occurs transparently. A message indicates the process was successful.

Procedure: How to Refresh Security Extracts on IBM i

From the Adapters list in the navigation pane or the Adapters folder of the DMC:

1. Right-click the configured JD Edwards EnterpriseOne adapter.
2. Select *Refresh Security Extracts*.

   The Refresh Security Extracts pane opens, indicating the Security mode you selected during adapter configuration: ROLE-based or GROUP-based (see *Configuration Parameters and Tasks for JD Edwards EnterpriseOne* on page 1217).

   The JDE tables required for this procedure are listed. Note that the list varies depending on the Security mode that is in effect.
3. In the input boxes provided, enter a library name for each of the JDE tables.
4. Click *Submit*.

   The refresh occurs transparently. A message indicates that the process has been successful.

Converting Synonyms for JD Edwards EnterpriseOne (Non IBM i Platforms Only)

You are now ready to convert synonyms. The conversions of the synonyms are affected by your option entries on the Master File Conversion pane. The following entries are added to the Master File:

- UDC (user-defined code) descriptor fields (if you check UDC on the Master File Conversion pane).
- Date fields are redefined as Gregorian dates, with the data format you select on the Conversion pane.
- Numeric fields are redefined with the correct decimal precision, as defined in the data dictionary repository.

Procedure: How to Convert Synonyms

1. From the Adapters list in the navigation pane, right-click *JD Edwards EnterpriseOne*, and select *Convert Master Files*. The Master Files Conversion pane opens at Part 1 of 2.
2. From the drop-down list, select the application in which you created the synonyms, then click *Next*.
3. On the second Master Files Conversion pane, select the option you wish to use.

The following image shows the second part of the Master Files Conversion pane.

- Select a date format from the drop-down list. The options are: YMD, YYMD, DMY, MDY, MDYY, DMYY, MYY, YYM. (YYMD is the default setting.) The selected format will be used only if the field is described as a DATE in the Data Dictionary.
- Select *N* for *Redefine*. IBM i only: *Y* is used for compatibility with earlier releases.
- Check the *UDC* box to ensure that UDC description fields are generated as DEFINEs (virtual fields) in the synonym.
- Do not check the Combine UDC box. IBM i only: It is used only for compatibility with earlier releases.
- Leave the *Hybrid* box unchecked (the default). (Windows only.)
- Under Options, do one of the following:

  Click the *Select Master File from a list* radio button, then from the drop-down list either select a file or choose *All*.

  or

  Click the *Enter specific filename to process* radio button and type a file name in the box provided.

4. Click *Convert Master File(s)* to start the conversion.

   A message is displayed when the process is successfully completed.

   Tip: You can click the *Back* button if you wish to return to the first synonym Conversion pane.

Except on Windows, you are now ready to report against these tables. On Windows, proceed to *Setting the UDCDIC Environment Variable (Windows only)* on page 1226.

Setting the UDCDIC Environment Variable (Windows only)

On Windows, before you can run reports against your synonyms, you must set the UDCDIC environment variable to locate a file that stores codes which are mapped to field names. This mapping provides significant data input benefits. For information about this variable, see *How to Set the UDCDIC Environment Variable on Windows* on page 1226.

Syntax: How to Set the UDCDIC Environment Variable on Windows

This step is required only on the *Windows* platform to ensure that the server can locate the udcdic.ftm file, which stores codes that are mapped to field names. This mapping provide significant data display benefits.

You can set the UDCDIC environment variable in a Managed Reporting user profile, outside of Managed Reporting as a variable in a procedure, or as a Windows environment variable where the server is installed.

Method 1: To set the variable in a Managed Reporting user profile or a procedure, use the following syntax

```
SETENV UDCDIC=reference_dir
```

where:

reference_dir

Is the path to the reference directory that contains the appropriate udcdic.ftm file.

For example,

```
SETENV UDCDIC=C:\ibi\apps\jowsec
```

This method is more flexible than method 2 because you can quickly change the path designation to point to a different udcdic.ftm file. (For example, this technique would be useful if you need to report against multiple UDC environments).

Method 2: To set UDCDIC as a Windows environment variable, navigate to the Windows facility for defining environment variables and enter:

Variable name: *UDCDIC*

Variable value: the path where the udcdic.ftm file is located. For example,

```
\ibi\apps\jowsec
```

The location of the reference directory can be anywhere on the drive. The UDCDIC environment variable is used to point to that location.

Chapter 47

Using the Adapter for JD Edwards World

The Adapter for JD Edwards World allows WebFOCUS and other applications to access JD Edwards World data sources. With this adapter, data in the JD Edwards World DBMS is displayed using rules contained in dictionary files, thereby ensuring that valid information is returned to the requesting program.

This adapter is available on the IBM i platform (formerly known as i5/OS).

In this chapter:

Installation Prerequisites

The software requirements for the Adapter for JD Edwards World are:

- **Operating System:** V5R4M0 or higher.
- Server Version 7 Release 7 or higher, should be installed and working. For details, see the *Server Installation* manual.

  Note: If the standard IADMIN ID was not used to install the Server, manually change ownership to the ID that was used.
- RDBMS connectivity - A Db2 connector must be configured. For more information, see *Using the Adapter for Db2* on page 497.

You must also verify that your end-user program can access the Server.

Configuring the Adapter for JD Edwards World

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

After the adapter is configured, you must refresh the metadata before you can create synonyms.

Procedure: How to Configure the Adapter for JD Edwards World From the Web Console

To configure the adapter:

1. From the Web Console Applications page, click *Get Data*.
2. Find the adapter on the Available list in the Web Console.
   You can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. Expand the *JD Edwards World* folder, and double-click the *A7.x - A9.x* connection.

   The Add JD Edwards World to Configuration pane opens.
4. Leave Security options unchecked (OFF) at this point. You will add them later.
5. Select a profile from the drop-down list to indicate the level of profile that the server is running: global, service, group, user. The standard server global profile, edasprof.prf, is the default.
6. Click *Configure* and then click *OK* in the confirmation message window.

   The adapter is added to the *Configured* folder in the navigation pane.

Managing JD Edwards World Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the data types.

Note: To create synonyms, you need to refresh the metadata, and also have both the JD Edwards World adapter and a Db2 adapter configured.

Procedure: How to Refresh the Metadata

1. Right-click the configured JD Edwards World adapter and select *Refresh Metadata Repository*.

   The Refresh Metadata Repository pane opens.
2. In the JD Edwards World Version field, choose *7.x* or *8.x*.
3. Enter the *location* of each of the following JDE files in the space provided. Only the library name is needed.

For Version 7	For Version 8	File Use
F0004 Library	F0004 Library	Contains JDE user-defined code types.
F0005 Library	F0005 LIbrary	Contains JDE user defined codes file.
F9202 Library	F9202 Library	Contains JDE data field specifications.
F9201 Library	F9210 Library	Contains JDE data field display text.
UDC Library		Contains the name of the new library to be created. It is recommended that you start the name with UDC*xxx*.

4. Click *Refresh Now* to create the files.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter.

1. From the Web Console *Applications* page, click *Get Data*.
2. Right-click the configured *JD Edwards World* adapter and select *Create Synonym*.

   The Select connection to create synonym page opens.
3. Click the Db2 connection to be used.
4. Complete the information required using the *Synonym Creation Parameters for JD Edwards World* on page 1231
5. The final step is setting JD Edwards World security options.

   For details, see *How to Set JD Edwards World Security* on page 1235.

Reference: Synonym Creation Parameters for JD Edwards World

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Select Synonym Candidates for Db2 (DB2CON1) Step 1 of 3

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Library

Type a string for filtering the Library (or Db2 Collection), inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select tables or views whose owner IDs begin with the letters ABC; %ABC to select tables or views whose owner IDs end with the letters ABC; %ABC% to select tables or views whose owner IDs contain the letters ABC at the beginning, middle, or end.

Object Name

Type a string for filtering the table, view, or object names, inserting the wildcard character (%) as needed at the beginning and/or end of the string. For example, enter: ABC% to select all tables, views, or objects whose names begin with the letters ABC; %ABC to select all whose names end with the letters ABC; %ABC% to select all whose names contain the letters ABC at the beginning, middle, or end.

Note: When you create a synonym for Db2 on the IBM i platform, standard IBM i naming conventions apply to the target data source. Therefore, the Adapter for Db2 supports the use of double-quotation marks around any library name and/or file name that contains lowercase or NLS characters.

Create Synonym for Db2 (DB2CON1) Step 2 of 3

Cardinality

Select the *Cardinality* check box to reflect the current cardinality (number of rows or tuples) in the table during metadata creation. Cardinality is used for equi-joins. The order of retrieval is based on the size (cardinality) of the table. Smaller tables are read first.

If the cardinality of the tables to be used in the application are dynamic, it may not be beneficial to choose this setting.

Build cluster using foreign keys (deprecated)

You can select the *Build cluster using foreign keys* check box to include within this synonym every table related to the current table by a foreign key. However, this option has been deprecated, as the recommended way to create a cluster is by using the Synonym Editor. The resulting multi-table synonym describes all of the foreign key relationships of this table.

One-part name

On the IBM i platform, the *One-part name* check box is unchecked by default. The unchecked behavior generates a table name that includes the explicit name of the library containing the table. For example, if you specified a library on the first Create Synonym pane, a qualified name like the following is automatically created in the Access File:

```
TABLENAME=MYLIB/MYTABLE
```

With this explicit type of entry in the Access File, at run-time the library is directly located and searched for the table name. If you select the check box, the explicit library name is not stored in the metadata (Access File). When the synonym is generated, the library portion of the table name is omitted from the Access File, and appears as follows:

```
TABLENAME=MYTABLE
```

With this type of entry in the Access File, at run time the library path of the user is searched until the table name is located.

For Subquery

Only available when *External SQL Scripts* is selected from the Restrict objects type to drop-down menu. When selected, a SUBQUERY keyword is added to the Access File of the generated synonym. If the corresponding SQL string has valid syntax that can be used in the FROM statement of the generated SQL (what is known as a Derived Table), then the SQL SCRIPT will be processed as a subquery embedded into a FROM clause. This usage allows for more flexibility. For example, the synonym can be used as a target for a JOIN.

If the SQL SCRIPT has parameter markers, such as ? or :, or the syntax contains constructs that are invalid for a derived table, for example ORDER BY, then this keyword should not be selected. At runtime, if SUBQUERY=Y is present and it is determined that the SQL SCRIPT cannot be used in the FROM statement, the setting will be ignored, and a FOC1782 warning message will be issued. The default is selected (SUBQUERY=Y).

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Customize data type mappings

To change the data type mappings from their default settings, select this check box. The customizable mappings are displayed.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Create Synonym for Db2 Step 3 of 3

Select date format

The options are: YMD, YYMD, DMY, MDY, MDYY, DMYY, MYY,YYM. (YYMD is the default setting.) The selected format will be used only if the field is described as a DATE in the DataDictionary.

Presumptive Join

Select the *Presumptive Joins* check box to include additional DEFINEs (virtual fields) for presumptive join fields in the synonym.

The default setting is *ON*.

Field Names

Select the *Long Fieldname* radio button (the default) to display the field descriptions as names on reports. Select the *Short Fieldname* radio button to use the JDE aliases as field names on reports. The default setting is *Long Fieldname*.

Language Code

Enter the appropriate Language Code, which exists in the JDE F9292 file. (Leave the field blank for English.)

UDC

Select the *UDC* check box to ensure that UDC description fields are generated as DEFINEs (virtual fields) in the synonym. The default setting is *ON*.

Combine UDC

Select the *Combine UDC* check box to Combine User Defined Code. The default setting is *OFF*.

Enabling JD Edwards World Security

You can set security options after you configure the adapter from the Web Console.

Procedure: How to Set JD Edwards World Security

1. From the list of configured adapters in the navigation pane, right-click *JD Edwards World*, and select *Properties*.

   The Change Connect Parameters pane for JD Edwards World opens.

2. You can accept the defaults (unchecked) or select one or more options by clicking the corresponding check boxes.

   Business Unit Security

   Check this box to enable automatic execution of JD Edwards World Business Unit Security. The server for IBM i automatically restricts user access to data, based on information retrieved from the F0001 and F0006 tables, and then adds appropriate WHERE conditions to the users submitted data access request.

   Unchecked (OFF) is the default setting.

   If you check this parameter, you cannot turn it OFF until the server is shut down and then restarted (with no parameter settings).

   Search Type Security

   Check this box to enable automatic execution of JD Edwards World Search Type Security. The server for IBM i automatically restricts user access to data, based on information retrieved from the F0005 table, and then adds appropriate WHERE conditions to the submitted data access request of the user.

   Unchecked (OFF) is the default setting.

   If you check this parameter, you cannot turn it OFF until the server is shut down and then restarted (with no parameter settings).

   Business Unit (for PA) Security

   Check this box to revert (if necessary) to an older security model used by this adapter.

   Unchecked (OFF) is the default setting.

   If checked, this option overrides standard Business Unit Security (as described above).

   Column Security

   Check this box to enable column security based on information in the F9401 file.

   Unchecked (OFF) is the default setting.

If you check this parameter, you cannot turn it OFF until the server is shut down and then restarted (with no parameter settings).

Select Profile

In Web Query this must be EDASPROF.

3. Click the *Configure* button to complete the process.

Enabling Tracing

You can easily trace any problem that arises using the Web Console tracing facility. For information about Trace options, see *Tracing Server Activity* in the *Server Administration* manual.

Frequently Asked Questions

Which Application directory should I store my JDE Master and Access Files in?

For a full WebFOCUS installation, we highly recommend storing all Master and Access Files in a separate Application directory from where the server was installed. You can then add the directory to the server's path prior to starting the server. This will not only avoid confusion about where these files reside, but will also make maintenance easier during server upgrades.

I've been using JD Edwards World under a 5.x server and I'm upgrading to a newer server level. Will the Master Files I built under the 5.x server work with 7.x?

Existing Master Files built with PSWCONV from the 5.x Server are *not* supported by the 7.x Server.

Enhancements have been made to the adapter conversion JDE procedure to accommodate the 7.x Server architecture. We suggest saving your existing 5.x Master Files as a backup, and recreating the metadata with the new version of the Adapter for JD Edwards.

Chapter 48

Using the Adapter for Jethro

Jethro is an acceleration engine that makes real-time Business Intelligence work on Big Data.

The Adapter for Jethro is available in the following modes:

- ODBC (on Windows only)
- JDBC (on Linux/Unix/Windows)

Only one mode (JDBC or ODBC) can be configured for a server instance.

In this chapter:

Obtaining the Jethro Drivers

The JDBC and ODBC drivers for Jethro can be downloaded from *https://jethro.io/driver-downloads*.

If you are using the ODBC driver, download the version (32 or 64 bit) that corresponds to the DataMigrator or WebFOCUS Reporting Server that you are running.

Preparing the Environment for the JDBC Driver

The following components are needed to use the JDBC adapter for Jethro:

- **Java.** To use this Java-based adapter, you must have Java, Version 1.7 or later, installed. Java can be downloaded from *http://www.java.com*.

  The location of the Java must be specified in an environment variable.

  If you are using Linux, add a line to your profile with the location where Java is installed. For example:

  ```
  export JAVA_HOME=/usr/lib/jvm/jre-1.7.0
  ```

If you have JDK installed:

```
export JAVA_HOME=/usr/lib/jvm/jdk-1.7.0
```

If you are using Windows, right-click *Computer* and click *Properties*. Then click *Advanced System Settings* and click *Environment Variables*. Add the locations to your PATH variable. For example:

```
C:\Program Files\Java\jdk7\bin\server;C:\Program Files\Java\jdk7\bin;
```

- **JDBC Driver**

  The JDBC driver consists two jar files (JethroDataJDBC.jar and protobuf-java-2.4.1.jar). They are included in the Jethro distribution at $JETHRO_HOME/jdbc and available for download from *https://jethro.io/driver-downloads*. If you are installing the server on the same system where Jethro is installed, you can point to the jar file as described in the next section. If you are installing the server on some other system, copy the file to a location of your choice.

Procedure: How to Configure the Java CLASSPATH

The location of the Jethro JDBC Driver must be specified to the server. If you are running the server on the same system as a Drillbit, you can specify its location. If you are running the server on another system, copy the files listed below to some location on your system and specify their location.

This can be done in the system CLASSPATH or in the DataMigrator or WebFOCUS Reporting Server IBI_CLASSPATH variable as follows:

1. From the Web Console menu bar, click *Workspace*

   or

   From the Data Management Console, expand the *Workspace folder*.

2. Expand the *Java Services* folder. Right-click *DEFAULT* and click *Properties*.

   The Java Services Configuration page opens.

3. Click the chevrons to expand Class Path.

   In the IBI_CLASSPATH box, enter the full location of the jar file. For example:

   ```
   /opt/jethro/current/JethroDataJDBC.jar
   /opt/jethro/current/protobuf-java-2.4.1.jar
   ```

   Note: The file names must be entered one per line.

If you are installing the adapter on a different system than where you have Apache Phoenix installed, copy the jar file to a location on that system.

Note: For a server running on Windows, use Windows syntax for directory names. For example:

```
C:\jethro\JethroDataJDBC.jar
C:\jethro\protobuf-java-2.4.1.jar
```

4. Scroll down and click the *Save and Restart Java Services* button.

Configuring the JDBC Adapter for Jethro

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Jethro JDBC Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the Jethro folder.
5. Click *Configure ODBC*.
6. In the URL box, enter the URL used to connect to your Drillbit. For more information, see *Jethro URL Configuration Settings* on page 1240.
7. In the Driver Name box, enter the following:

   ```
   com.jethrodata.JethroDriver
   ```

8. Enter your User and password. The default values are jethro/jethro.
9. Click *Test*. You should see a list of data sources on your server.

10. Click *Configure*.

Reference: Jethro URL Configuration Settings

The Adapter for Jethro is under the SQL group folder.

The URL configuration for the Jethro adapter is:

```
jdbc:JethroData://host:port[;host:port]…/instance_name
```

where:

host

Is the name or IP addresses where the Jethro server is running.

port

Is the port number for Jethro. The default value is 9111.

instance_name

Is the name of the Jethro server instance.

Troubleshooting

If the server is unable to configure the connection, a dialog box opens with an error message. The message typically begins with the following:

```
(FOC1400) SQLCODE IS -1 (HEX: FFFFFFFF) XOPEN: nnnn
```

where:

nnnn

Is the message number returned.

Some of the more common errors are:

```
(FOC1500) : (-1) [00000] JDBFOC>> connectx():
(FOC1500) : java.lang.UnsupportedClassVersionError:
org/apache/drill/jdbc/Driver :
(FOC1500) : Unsupported major.minor version 51.0
(FOC1479) ERROR CONNECTING TO SQL DATABASE
```

This indicates that your Java version is less than 1.7, which is required.

Configuring the ODBC Adapter for Jethro

Configuring the adapter consists of specifying connection and authentication information for the connection that you want to establish.

Note that the ODBC Adapter for Jethro is only available for servers running on Windows.

Procedure: How to Configure the ODBC Adapter for Jethro

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

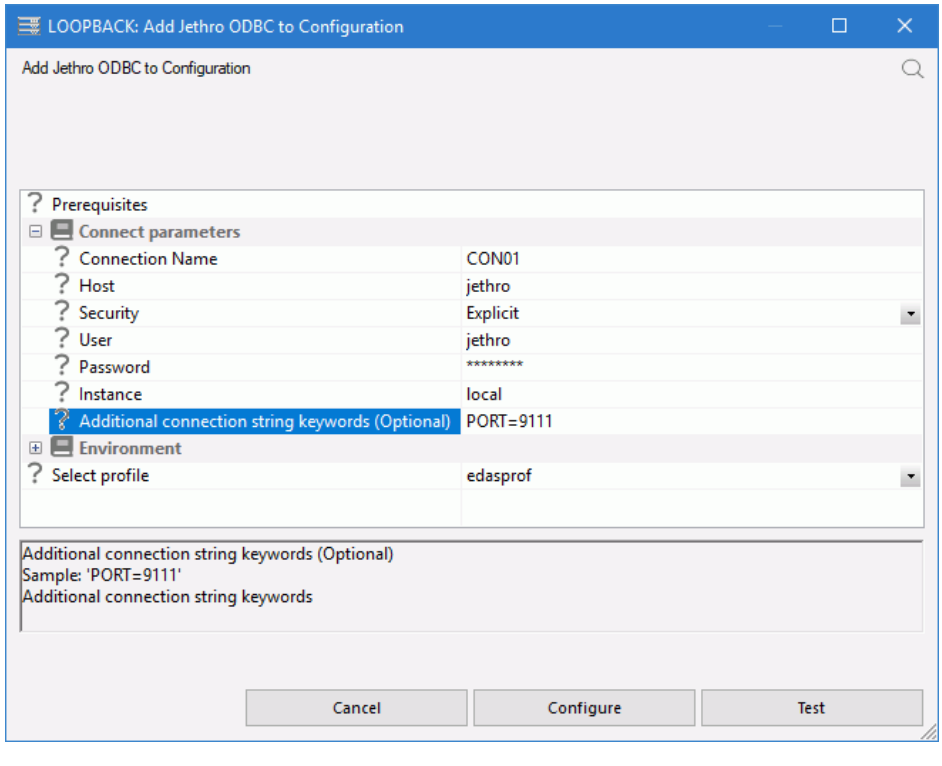
   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. Right-click *Jethro* and click *ODBC*.

   The Add Jethro ODBC to Configuration dialog box opens, as shown in the following image.



4. Enter the values for the parameters as described in *Connection Attributes for the ODBC Adapter for Jethro* on page 1242.
5. Click *Configure*.

Reference: Connection Attributes for the ODBC Adapter for Jethro

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name
Logical name used to identify this particular set of connection attributes. The default is CON01.

Host
Name of the Host where the Server is running.

Security
Select *Explicit* from the pull-down menu. Type the user ID (jethro by default) and password (also jethro by default) for your Jethro server.

Instance
Type the instance name for your Jethro server. For example, demo.

Additional Connection-String Keywords
Type PORT=*port_number*, where *port_number* is where your Jethro server is listening, 9111 by default.

Creating Synonyms With Jethro

Synonyms define unique names, or aliases, for each Jethro table that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Jethro table.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter and a connection.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

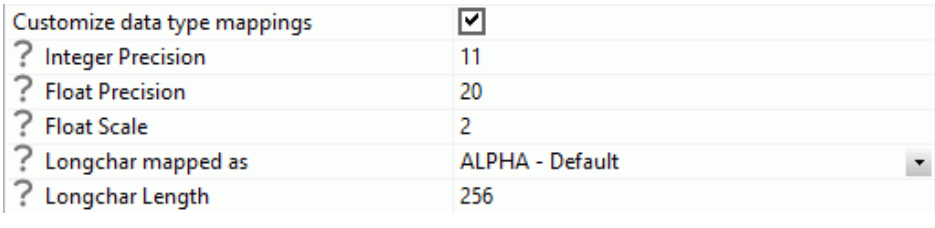
Depending on the type of adapter you chose, one of the following options appears on the context menu.

- **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.
5. Optionally, expand the *Customize data type mappings* section and enter a value for CONV_LONGCHAR_LEN or numeric precision, as shown in the following image.



6. Select the check box for the objects that you want to create synonyms for. If you want to change the name of the synonym from the default name, click the name and edit it as needed.
7. Click *Create Synonym*.

The Status pane indicates that the synonym was created successfully. The synonym is created and added under the specified application directory.

Chapter 49

Using the Adapter for JSON

The Adapter for JSON (JavaScript Object Notation) allows applications to access JSON documents as data sources. The adapter traverses the hierarchical trees and returns an answer set to the requesting application.

In this chapter:

Preparing the JSON Environment

The Adapter for JSON does not require any environment variables to be configured.

Configuring the Adapter for JSON

You can configure the Adapter for JSON from the Web Console or the Data Management Console.

Procedure: How to Configure the Adapter

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Note: The JSON adapter is in *XML-based* drop-down.. No input parameters are required.

Associating a Master File With a JSON Document

You must explicitly issue a FILEDEF command to associate a Master File with a JSON document. In order to properly code the FILEDEF command, you need to determine how the JSON documents are organized. If the documents are all in one file, the organization is called a COLUMN. If there are various documents in one directory, then the organization is called a COLLECTION.

Source	Collection Organization	Column Organization
disk	supported	supported
http	not supported	supported
https	not supported	supported

Syntax: How to Associate a Master File With a JSON Document

```
FILEDEF ddname source filename
```

where:

ddname

Is the logical reference name matching the desired Master File.

source

Is the location of the JSON document. Possible values are http, https, and disk.

filename

For a JSON Column, is the full path to the source file.

For a JSON Collection, is the full path to the source directory. The directory name must be followed by the wildcard characters '*.*'.

The file name must start with 'http://' or 'https://' if the JSON documents are to be read using an HTTP or HTTPS session.

Example: Issuing a FILEDEF Command for a JSON Column

Note: If you are working on the Web Console or Data Management Console Create Synonym panes, see *Synonym Creation Parameters for JSON* on page 1249 for details about how FILEDEFs are created.

For Windows, when you have the ordercol.JSON document under C:\, use the following FILEDEF in your profile:

```
FILEDEF ordercol disk C:\ordercol.JSON
```

For UNIX, when you have the ordercol.JSON document under /usera/JSON/, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK /usera/JSON/ordercol.JSON
```

For z/OS, when you have the ordercol.JSON document in TEST.JSON, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK //'TEST.JSON'
```

For HTTP and HTTPS, when you have the ordercol.JSON document under http://www.test.com/JSONtest/ (or https://www.test.com/JSONtest/), use the following FILEDEF in your profile:

```
FILEDEF order http http://www.test.com/JSONtest/ordercol.JSON
```

or

```
FILEDEF order http https://www.test.com/JSONtest/ordercol.JSON
```

Example: Issuing a FILEDEF Command for a JSON Collection

Note: If you are working on the Web Console or Data Management Console Create Synonym panes, see *Synonym Creation Parameters for JSON* on page 1249 for details about how FILEDEFs are created.

For Windows, when you have the order1.JSON and order2.JSON documents under C:\ORDERS, use the following FILEDEF in your profile:

```
FILEDEF order disk C:\orders\*.*
```

For UNIX, when you have the ordercol.JSON document under /usera/orders, use the following FILEDEF in your profile:

```
FILEDEF ordercol DISK //'TEST.JSON'
```

For z/OS, when you have the order document in TEST.JSON, use the following FILEDEF in your profile:

```
FILEDEF order DISK /usera/orders/*.*
```

Managing JSON Metadata

When the server accesses a data source, it needs to know how to interpret the data that it finds. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the JSON data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each JSON data structure that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given JSON document.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.

- ❑ **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- ❑ **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for JSON

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

You can create a synonym based on a JSON document:

- ❑ Select a document instance (Step 1) and click *Create Synonym based on Document Instance*.

Select Document Instance parameters (Step 1 of 2)

Use HTTP URL

Enables you to select a document instance from a URL. This selection requires a Base Location, Document Name, and Document Extension.

Base Location

Defines the location of the document instance.

- If *Use HTTP URL* is not selected, enter a physical path or application directory and the JSON document name, or click the ellipsis (...) to navigate to the document.
- If *Use HTTP URL* is selected, enter the http address of a directory that contains the JSON document you are using to create the synonym. (This functionality is not available when the JSON document is a local file.) The URL must start with http:// or https://.

Document Name

Enter the name of the JSON document.

Document Extension

Enter the document extension. The default is JSON.

Create Synonym based on Document Instance

Clicking this button enables you to create the synonym from the document instance.

Create Synonym for JSON (Step 2 of 2)

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Synonym Name

Indicates the name that will be assigned to the synonym. To assign a different name, replace the displayed value.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Accessing JSON Documents From a Relational DBMS JSON Data Type

JSON documents might be stored in any fields or columns in any data source. Reporting from such documents is supported by defining their structure as subtrees attached to a parent segment which describes the original data.

The synonym creation process must be run against the data in the DBMS and against the JSON document. The two Master Files must then be combined to make the JSON Master File a child of the Master File created against the DBMS. A FILEDEF is not needed in this instance.

Procedure: How to Access JSON Data From an RDBMS Using Web Console or Data Management Console Tools

1. Using the Web Console or the Data Management Console Create Synonym facility, generate a synonym for an RDBMS data source that contains a column of JSON data. Regardless of the data type used to contain the JSON data in the native data source, it will be mapped as a TX column in the Master File synonym. (For many RDBMS engines, the CLOB data type is mapped to TX.)
2. Open the generated Master File in the Synonym Editor. The Master File appears in the right pane in Text View. For example, the Master File for a Db2 data source might look as follows:

```
FILENAME=TESTJSON, SUFFIX=DB2     , $
SEGMENT=TESTJSON, SEGTYPE=S0, $
FIELDNAME=STORE, ALIAS=STORE, USAGE=A30, ACTUAL=A30, $
FIELDNAME=ADDRESS, ALIAS=ADDRESS, USAGE=A20, ACTUAL=A20,
MISSING=ON, $
FIELDNAME=GLOSS, ALIAS=GLOSS, USAGE=TX50, ACTUAL=TX,
MISSING=ON, $
```

3. From the DMC, right-click a column described as TX that contains JSON data. The pop-up menu contains the *Pivot* option.
4. Select *Pivot*, then *Multiple values to rows*. This option reads the JSON column directly and creates a new segment with SEGSUF=JSON.

   The *Select mapping source* dialog box opens.

   a. Select *Rows to sample for structural analysis* and click *Next*.

      The *Column mapping* dialog box opens displaying two rows from the column that is being pivoted.

      Examine the data to make sure it looks like JSON.

   b. In the *Select data type* pull-down list, select *JSON* and click *Apply*.

      The resulting Master File contains the definition of the JSON data, represented as a new DUMROOT segment with SEGSUF=JSON, which appears in the Text View pane following the original RDBMS segment.

      You can expand DUMROOT to see the names of the fields found in the JSON.

      You can right-click DUMROOT to see the values of those fields.

The Master File might now look as follows, with the DUMROOT segment containing the data from the JSON column:

```
FILENAME=testjson, SUFFIX=DB2     , $
  SEGMENT=TESTJSON, SEGTYPE=S0, $
    FIELDNAME=STORE, ALIAS=STORE, USAGE=A30, ACTUAL=A30, $
    FIELDNAME=ADDRESS, ALIAS=ADDRESS, USAGE=A20, ACTUAL=A20,
      MISSING=ON, $
    FIELDNAME=GLOSS, ALIAS=GLOSS, USAGE=TX50, ACTUAL=TX,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL), $
  SEGMENT=DUMROOT, SEGTYPE=S0, SEGSUF=JSON    ,
      PARENT=TESTJSON, POSITION=GLOSS, $
    FIELDNAME=DUMROOT, ALIAS=JSON_DUMMY_EL, USAGE=A1, ACTUAL=A1,
        ACCESS_PROPERTY=(INTERNAL), $
    FIELDNAME=TITLE, ALIAS=title, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSARY, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSDIV, ALIAS=GlossDiv, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSARY, PROPERTY=ELEMENT,  $
    FIELDNAME=TITLE1, ALIAS=title, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSDIV, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSLIST, ALIAS=GlossList, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSDIV, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSENTRY, ALIAS=GlossEntry, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSLIST, PROPERTY=ELEMENT,  $
    FIELDNAME=ID, ALIAS=ID, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=SORTAS, ALIAS=SortAs, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSTERM, ALIAS=GlossTerm, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
```

```
    FIELDNAME=ACRONYM, ALIAS=Acronym, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=ABBREV, ALIAS=Abbrev, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSDEF, ALIAS=GlossDef, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=PARA, ALIAS=para, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSDEF, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSSEE, ALIAS=GlossSee, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
  SEGMENT=GLOSSSEEALSO, SEGTYPE=S0, PARENT=GLOSSARY, $
    FIELDNAME=GLOSSSEEALSO, ALIAS=GlossSeeAlso, USAGE=A55,
ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSDEF, PROPERTY=ELEMENT,  $
```

5. From the Synonym Editor's File menu, save the updated Master File.

Procedure: How to Access JSON Data From an RDBMS Manually

Suppose that you have a table in an RDBMS with one or more columns storing JSON data. In order to report from the JSON data, following these steps:

1. Create the Master File for the relational data source using the format for that DBMS.

```
FILENAME=TESTJSON, SUFFIX=DB2     , $
  SEGMENT=TESTJSON, SEGTYPE=S0, $
    FIELDNAME=STORE, ALIAS=STORE, USAGE=A30, ACTUAL=A30, $
    FIELDNAME=ADDRESS, ALIAS=ADDRESS, USAGE=A20, ACTUAL=A20,
      MISSING=ON, $
    FIELDNAME=GLOSS, ALIAS=GLOSS, USAGE=TX50, ACTUAL=TX,
      MISSING=ON, $
```

2. Create a Master File for the JSON document in the column of the RDBMS table. If there are two JSON documents with different formats, you must create a Master File for each one.

3. Manually combine the Master Files. On each root segment for the JSON Master File, add three fields: position, parent, and segsuf. The POSITION keyword identifies the field containing the JSON document. The PARENT field describes the original data source. The field SEGSUF defines the root segment of a JSON document representing sub-tree. The total length of all fields in the Master File must not exceed the FOCUS limitation of 32k. If it does, the query will fail.

```
FILENAME=BASEAPP_GLOSSARY, SUFFIX=JSON    ,
 DATASET=c:\json\glossary.json, $
  SEGMENT=GLOSSARY, SEGTYPE=S0, $
    FIELDNAME=GLOSSARY, ALIAS=glossary, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL), $
    FIELDNAME=TITLE, ALIAS=title, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSARY, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSDIV, ALIAS=GlossDiv, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSARY, PROPERTY=ELEMENT,  $
    FIELDNAME=TITLE1, ALIAS=title, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSDIV, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSLIST, ALIAS=GlossList, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSDIV, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSENTRY, ALIAS=GlossEntry, USAGE=A1, ACTUAL=A1,
      MISSING=ON, ACCESS_PROPERTY=(INTERNAL),
      REFERENCE=GLOSSLIST, PROPERTY=ELEMENT,  $
    FIELDNAME=ID, ALIAS=ID, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=SORTAS, ALIAS=SortAs, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $
    FIELDNAME=GLOSSTERM, ALIAS=GlossTerm, USAGE=A55, ACTUAL=A55,
      MISSING=ON,
      REFERENCE=GLOSSENTRY, PROPERTY=ELEMENT,  $

    REFERENCE=GLOSSDEF, PROPERTY=ELEMENT,  $
```

Conversion

The data in a JSON document may reflect dates or numeric values, however, all the fields in a Master File synonym are set to the ALPHA data type.

Numeric Values

In order to enable arithmetic operations on numeric fields, the data type specified in the USAGE attribute of a numeric field needs to be modified, depending on the data in the JSON document, to one of the following data types: Integer (I), Double Float (D), or Decimal (P). If the data type is modified to Double Float or Decimal, use scale and precision as necessary to describe the data in the JSON document.

Furthermore, it is recommended that the length of the ALPHA data type specified in the ACTUAL attribute of the numeric field be modified to reflect the maximum length of the data in the JSON document.

Dates in JSON

In order to enable arithmetic operations on dates, the data type specified in the USAGE attribute of a date field needs to be modified, depending on the date format used in the JSON document, to one of the following data types: YYMD, MDYY, or DMYY.

Furthermore, the length of the ALPHA data type specified in the ACTUAL attribute of the date field needs to be modified to 10.

Note:

- Once you have set the data type in the Master File to one of the date data types, you must make sure that in each of the JSON documents from which you report the date format is the same as the one you defined in the Master File. If the data types differ, an error will result.
- The date format in the answer set is not derived from the date format used in the JSON document and is always set to YYYY/MM/DD.

Example: Using Dates in JSON

If in the JSON document you have the following format:	Then use USAGE=
1996-01-30	YYMD
01-30-1996	MDYY
30-01-1996	DMYY

Chapter 50

Using the Adapter for Kafka

The Adapter for Kafka provides access to and reporting against messages resident in the Apache Kafka environment.

In this chapter:

Preparing the Kafka Environment

The Adapter for Kafka can be configured with or without support for Apache Avro, which is a data serialization system. It uses a schema to perform serialization and deserialization of Kafka messages.

The Adapter for Kafka without support for Apache Avro requires the kafka-clients jar file and the slf4j-api Jar file as part of the configuration process. Once you download the Kafka binaries from the Apache Kafka download site (*https://kafka.apache.org/downloads*), the necessary .jar files are in the *lib* directory.

You must add the .jar files to the IBI_CLASSPATH variable when you configure the adapter.

The Adapter for Kafka with support for Apache Avro requires a different set of .jar files to be configured in IBI_CLASSPATH, in order to deserialize the messages being polled from the Kafka environment. These .jar files are included as part of the Confluent Platform download (*https://www.confluent.io/download/*).

You can also configure the Adapter for Kafka in a Docker container.

Complete prerequisites and examples of configuration options are included in the *Prerequisites* link on the right-click menu for the adapter.

Configuring the Adapter for Kafka

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Procedure: How to Configure the Adapter for Kafka

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click *Kafka* and click *Configure*.

Reference: Connection Attributes for Kafka

The Adapter for Kafka is under the Files group of adapters.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Basic Connection Attributes

Describes the connection attributes required for all connections to Kafka.

Connection Name

Is the logical name used to identify this set of connection attributes. The default is CON01.

Server

Is the host name of the Kafka host.

Port

Is the port on which Kafka listens, for example, 9092.

Security

There are three methods by which a user can be authenticated when connecting to the database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to Kafka, at connection time, for authentication as a standard login.
- **Password Passthru.** The user ID and password received from the client application are passed to Kafka, at connection time, for authentication as a standard login.
- **SASL GSSAPI.** The adapter connects to Kafka using Simple Authentication together with Security Layer and Generic Security Service Application Program Interface.

User

Is the primary authorization ID by which you are known to the data source. This field appears when the security selected is Explicit.

Password

Is the password associated with the primary authorization ID. This field appears when the security selected is Explicit.

JAAS Login File

Is the Java Authentication and Authorization Service Login Configuration File defining the user authentication and authorization services used by Kafka. This field appears when the security selected is SASL GSSAPI.

IBI_CLASSPATH

Lists search paths to required .zip and .jar files, each on a separate line. From the right-click menu for the adapter on the New Datasource list or the Configured Adapters list, select *Prerequisites* for more information.

Select profile

Select the profile in which to store the connection attributes. The default is edasprof, the server global profile.

Advanced HTTP Connection Options

Describes advanced security connection attributes.

SSL Configuration File

Is the Secure Socket Layer configuration file that defines the SSL configuration parameters used by Kafka.

TRUSTSTORE Location

Is the location of the file used to store certificates from trusted authorities.

TRUSTSTORE Password

Is the password required to read the contents of the TRUSTSTORE.

KEYSTORE Location

Is the location of the file used to store Private Key certificates.

KEYSTORE Password

Is the password required to read the contents of the KEYSTORE.

KEY Password

Is the password required to read the Private Key.

Managing Kafka Metadata

When the server accesses a data source, it needs to know how to interpret the data that it finds. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Kafka data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each data structure that is accessible from a server. Synonyms are useful because they hide the location and identity of the underlying data source from client applications. They also provide support for extended metadata features of the server such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while enabling client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and Access File based on a given Kafka topic.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

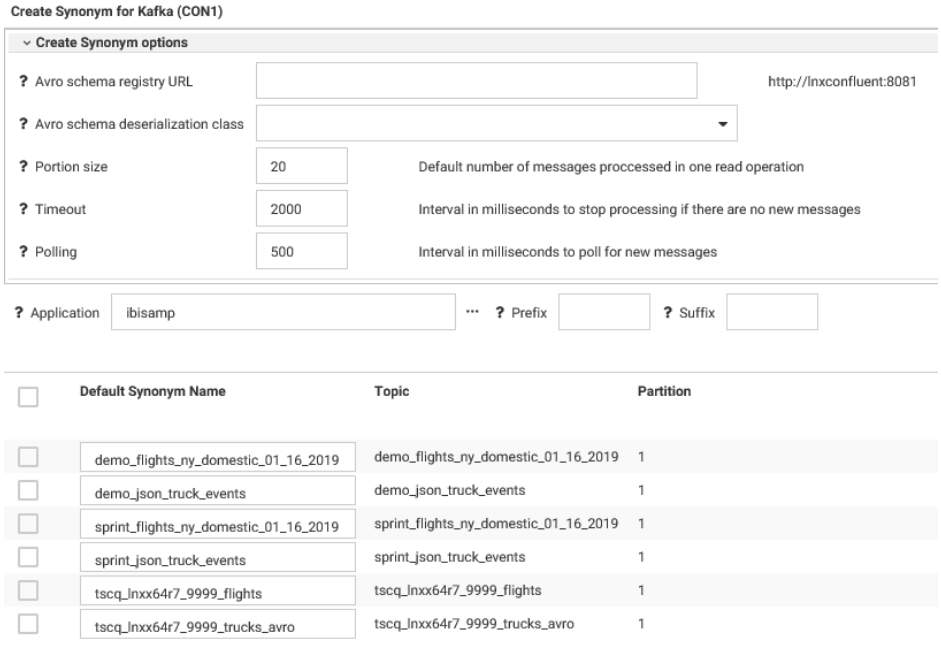
   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for Kafka

The Create Synonym for Kafka page is shown in the following image.



The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. When you have configured the parameters and made the selections you need, click the *Create Synonym* button on the ribbon, which generates the synonym based on your entries.

To create synonyms for one or more Kafka topics, right-click a connection and click *Show Topics*. The Create Synonym for Kafka page opens on which you can select synonym objects and configure the following properties for topics within the Kafka environment.

Create Synonym for Kafka (Step 1 of 2)

Avro Schema Registry URL

Is the URL to the Apache Avro data serialization system.

Avro Schema Deserialization Class

Select the class used to deserialize the Avro Schema.

Portion Size

Is the default number of messages processed in one read operation. The default value is 20.

Timeout

Is the Interval, in milliseconds, to stop processing if there are no new messages. The default value is 2000.

Polling

Is the Interval, in milliseconds, to poll for new messages. The default value is 500.

Create Synonym for Kafka (Step 2 of 2)

Select the check boxes next to the topics for which you want to create synonyms.

Default Synonym Name

Indicates the name that will be assigned to the synonym. To assign a different name, replace the displayed value.

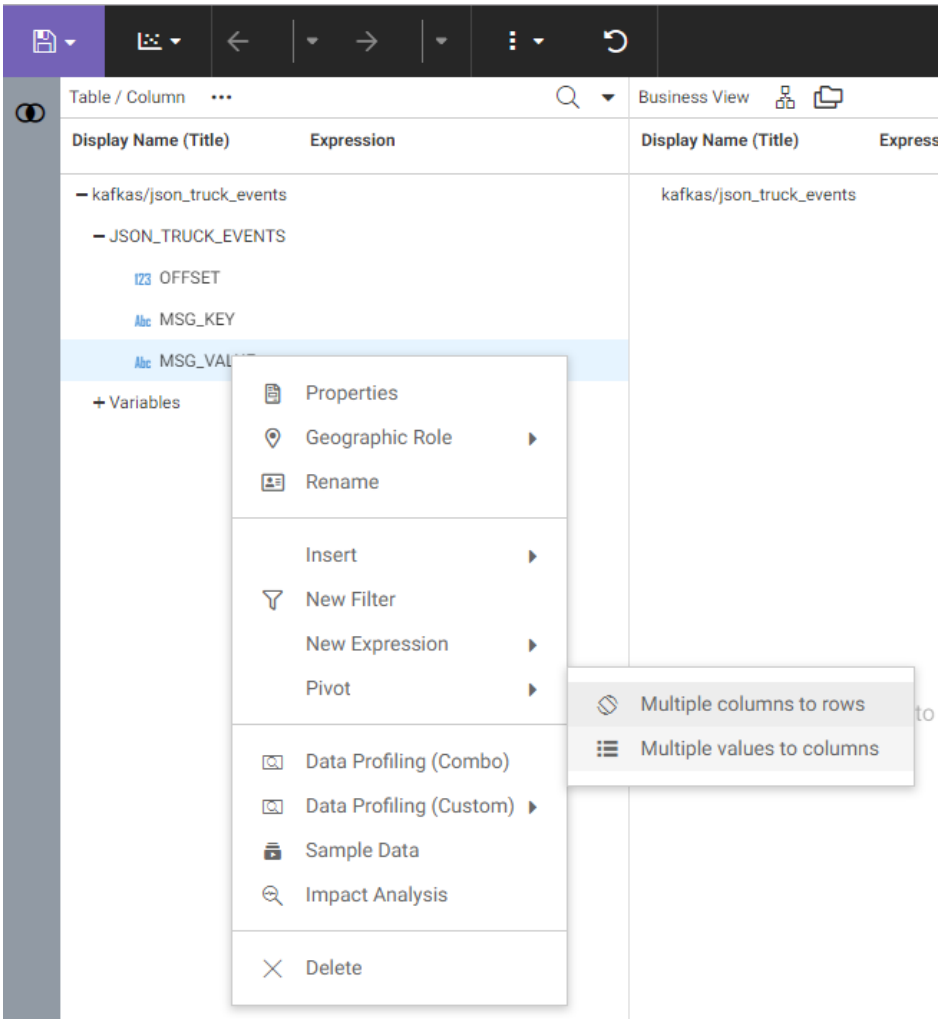
Reference: Managing Synonyms

Once you have created a synonym, you need to do the following to create a proper response segment dependent on the delimiter.

1. Open the synonym in the Synonym Editor by double-clicking the synonym name or right-clicking the synonym name and clicking *Open*.

   Depending on the Topic, the Message Value can delimit the components of each message in a variety of ways, for example, JSON, Pipe, or Comma. Pivoting this field will create a new segment in the synonym that has a field for each item within the Message Value.

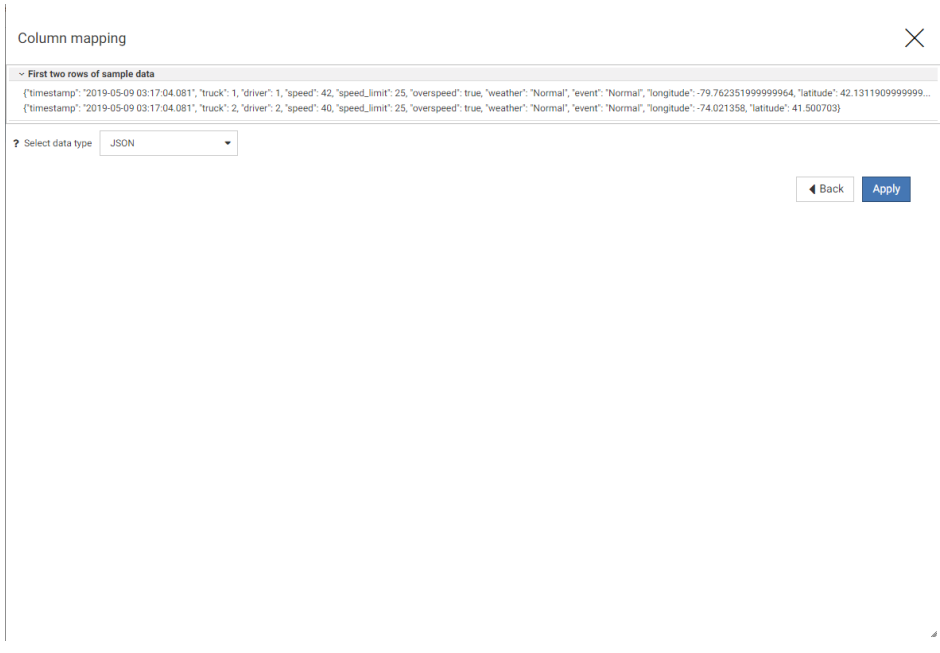
2. Pivot the field containing the message values by right-clicking the field, clicking *Pivot*, and clicking *Multiple values to columns*, as shown in the following image.



The Select Mapping Source page opens in which you can enter a number of rows to sample for structural analysis of the column to be pivoted. The default value is 1000.

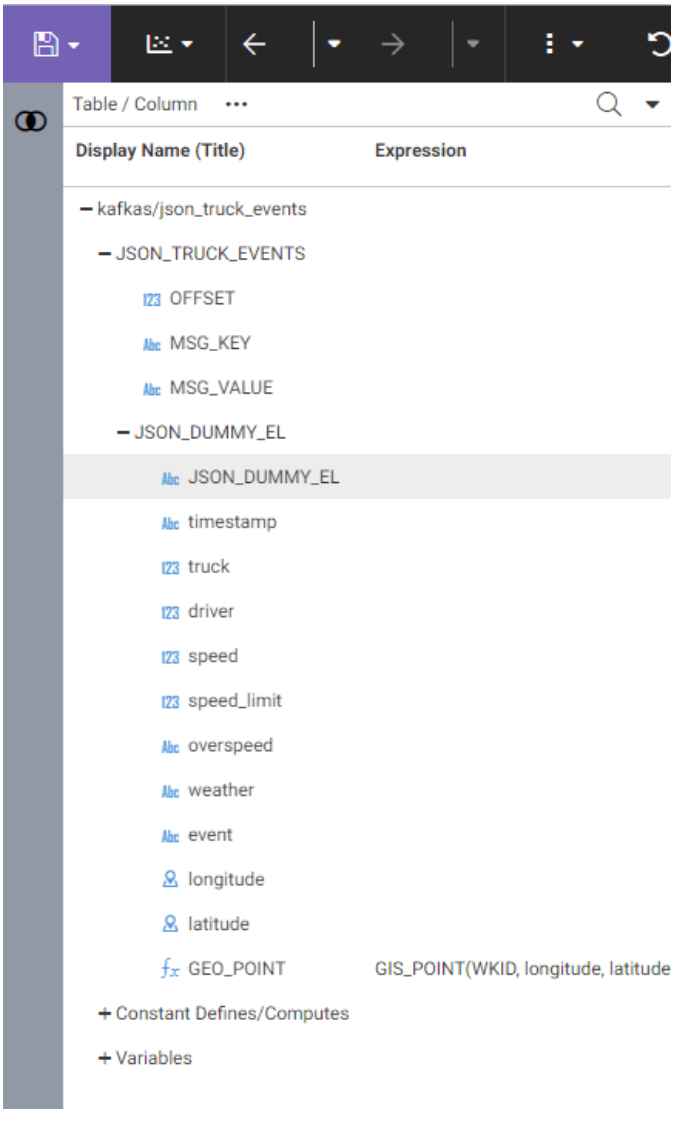
3. Click *Next*.

The Column Mapping page opens on which you can select the data type. A couple of rows of sample data are listed, as shown in the following image.



4. Click *Apply*.

A new segment is added to the synonym that lists each item from the JSON object as a separate field, as shown in the following image.



5. Save this synonym for use in reporting and messaging.

Chapter 51

Using the Adapter for Lawson

The Adapter for Lawson allows applications to access Lawson data sources.

The Adapter for Lawson automatically applies the appropriate Lawson security rules as defined in the Lawson LAUA repository. The adapter transparently generates dynamic DBA statements and/or dynamic WHERE clauses.

In this chapter:

Adapter for Lawson: Overview

The Adapter for Lawson works behind the scenes to control end users' access to the data in the Lawson system. When a user makes a request against a Lawson table, the Adapter for Lawson asks the following questions:

- Is this a Lawson File?
- Is this a Lawson User?
- Does the user have access to this table?

Once these questions have been answered, the Adapter for Lawson does the following:

- Dynamically generates DBA for any Application Security System Code, Record Level security, File Security, and Field Security. For more information on DBA, see the *Describing Data* manual.
- Generates WHERE clauses for any Lawson Company and Process Level, Record Security, and Field Security restrictions. These WHERE clauses are appended to any requests for data made to the Lawson data.

In order for the Adapter for Lawson to work properly, you must complete the following steps:

1. Verify that the server is installed.
2. Configure the Adapter for Lawson.
3. On the machine where Lawson is running, extract the Lawson security information into flat files using the lawsdmp.sh utility.
4. Copy or FTP the Lawson security information flat files to the server.
5. Refresh the security extracts to change the flat files into a format the server can understand.
6. Configure the data adapter and create the synonyms for the tables you plan to report from.

Configuring the Adapter for Lawson

You can configure the adapter using the Web Console or the Data Management Console (DMC).

Procedure: How to Declare Connection Attributes

You can configure the adapter from either the Web Console or the Data Management Console.

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.

In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Lawson

The *Lawson* adapter is under the *ERP* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

DBMS Suffix

Specify the suffix of the database that Lawson is using. Possible values are:

`SQLORA` - Oracle

`SQLMSS` - Microsoft SQL Server

`SQLINF` - Informix

`SQLDB2` - Db2

Default Product Line

This value is customized by the site when the Lawson system is installed.

Server Authentication

- Check this box if the reporting server is secured. This option applies if every Lawson user has a user ID on the reporting server system.
- Leave the box unchecked if the reporting server is unsecured. This option applies if every Lawson user ID and password is stored and is being authenticated by Managed Reporting and/or a self-service application:
  - For Managed Reporting, the user ID must be the Lawson User ID.
  - For Self Service requests, the Lawson ID must be passed to the server.

  In either case, the IBI_REPORT_USER variable must be set to the Lawson User ID.

Windows-based Lawson?

Check this box if the Lawson application system is Windows-based.

Leave the box unchecked if it is UNIX-based.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Preparing the Lawson Environment

Preparing the Lawson environment involves extracting security information from Lawson, copying that information from flat files to the server, and refreshing the security extracts.

Important: Automatic Passthru must be disabled against Lawson data. To set Automatic Passthru off, enter the following command in the server profile, edasprof.prf:

```
SET APT = OFF
```

Procedure: How to Extract the Lawson Security Information

Perform the following steps on the machine where Lawson is running:

1. On the Lawson System, create the ibi_officer user ID, or any user ID with Security Officer capabilities. (This ID must be allowed to run the Lawson RNGDBDUMP command.)
2. Copy *lawsdmp.sh* and *lawsdmpu.sh* from the bin directory and *lawsfil.dat* from the etc directory of EDAHOME into the home directory of the ibi_officer.

   EDAHOME is the location of the files that run your server. The following table shows the default locations for EDAHOME.

Operating system	EDAHOME default directory location and name
Windows	\ibi\srv77\home
UNIX	/home/iadmin/ibi/srv77/home
IBM i (formerly known as i5/OS)	/home/iadmin/ibi/srv77/home

3. Change the execute attribute of lawsdmp.sh and of lawsdmpu.sh to *On*.
4. Schedule or run either lawsdmp.sh or lawsdmpu.sh to extract the latest changes to the Lawson Security System:

   - Use lawsdmp.sh for initial setup and when you wish to refresh all files. (This script extracts all necessary security information.)
   - Use lawsdmpu.sh when you wish to refresh *only* the user information file.

Procedure: How to Copy the Lawson Security Information Flat Files to the Server

1. Copy the lawsftp.dat file from the etc directory in EDAHOME to the lawsec app directory.
2. Edit lawsftp.dat to indicate the host name, user ID, and password of the remote machine that contains the extracts derived from running the lawsdmp.sh script.
3. If the server with the Adapter for Lawson is on the same machine as the Lawson System, copy the extracted files, *.ftm and *.cvs files, from the lawsdmp run home directory of ibi_officer to the Lawson Security Directory (the lawsec directory in APPROOT) of the server.

   If the server with the Adapter for Lawson is not on the same machine, run ftp with lawsftp.dat as input to ftp the extracted files to the Lawson Security Directory (the lawsec directory in APPROOT), as follows:

   ```
   ftp -niv < lawsftp.dat
   ```

Procedure: How to Refresh Security Extracts

1. If you have not already done so, start the server and the Web Console and/or Data Management Console (DMC).
2. Right-click the configured adapter on the Adapters navigation pane and choose *Refresh Security Extracts* from the menu.

This process creates the LAW* FOCUS files needed by the Adapter for Lawson to apply the necessary filtering to queries against the Lawson database files.

Managing Lawson Metadata

Once the Adapter for Lawson is configured and the environment properly set up, you must configure a data adapter (Db2, Microsoft SQL Server, Informix, or Oracle) to access the Lawson data and create synonyms for the associated database management system.

Updating Lawson Security Information

Every time you change Lawson security information, you need to update the server files.

The update process is similar to the one you use for the initial extraction of Lawson security information.

Procedure: How to Update Lawson Security Information

1. Run lawsdmp.sh (or lawsdmpu.sh) to extract the latest changes to the Lawson Security System in the ibi_officer user ID home directory.

2. If the server with the Adapter for Lawson is on the same machine as the Lawson System, copy the extracted files, *.ftm and *.cvs, from the lawsdmp run home directory of ibi_officer to the Lawson Security Directory (the lawsec directory in APPROOT) on the server. You can find these files in the lawsec directory.

   If the server is not on the same machine, run ftp with lawsftp.dat as input used to ftp the extracted files to the Lawson Security Directory (the lawsec directory in APPROOT). This should be done as follows:

   ```
   ftp -niv < lawsftp.dat
   ```

3. Start the server and the Web Console or Data Management Console.
4. From the Web Console menu bar, click *Adapters*

   or

   from the Data Management Console, expand the *Adapters* folder.

   The Adapters folder opens.
5. On the navigation pane, right-click the configured Lawson adapter and select *Refresh Security Extract* from the menu.

Chapter 52

Using the Adapter for LinkedIn

This section describes how to configure the LinkedIn Adapter.

In this chapter:

LinkedIn Adapter Overview

The LinkedIn Adapter is used to report against information resident in the LinkedIn environment. You can configure the LinkedIn Adapter using the Reporting Server Web Console. The adapter requires a connection, which stores the access token. A valid LinkedIn access token is needed to issue LinkedIn API calls. The token is associated with a LinkedIn application and a specific LinkedIn member. The access token is valid for 60 days after which a new access token would need to be obtained and configured.

The connection page shows permissions that will be granted to the LinkedIn application. You can uncheck permissions that should not be granted. The connection process will use only checked permissions. Authentication will take place even if no permissions are granted.

Creating a LinkedIn Application

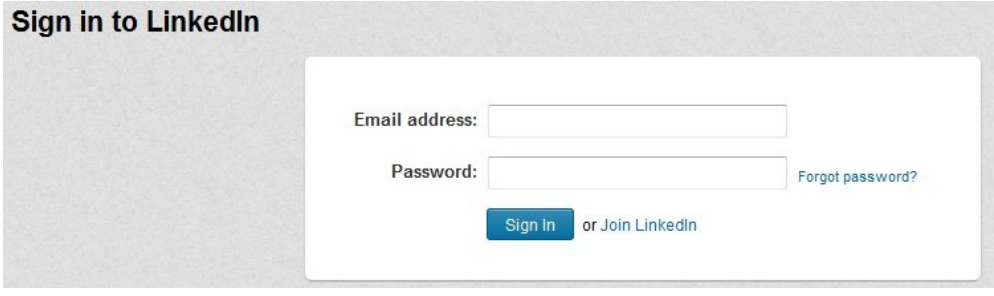
A LinkedIn application needs to exist before configuring the LinkedIn adapter

Procedure: How to Create a LinkedIn Application

1. From a browser, enter the following URL in a web browser:

   `https://www.linkedin.com/secure/developer`

A Sign in to LinkedIn screen opens, as shown in the following image.

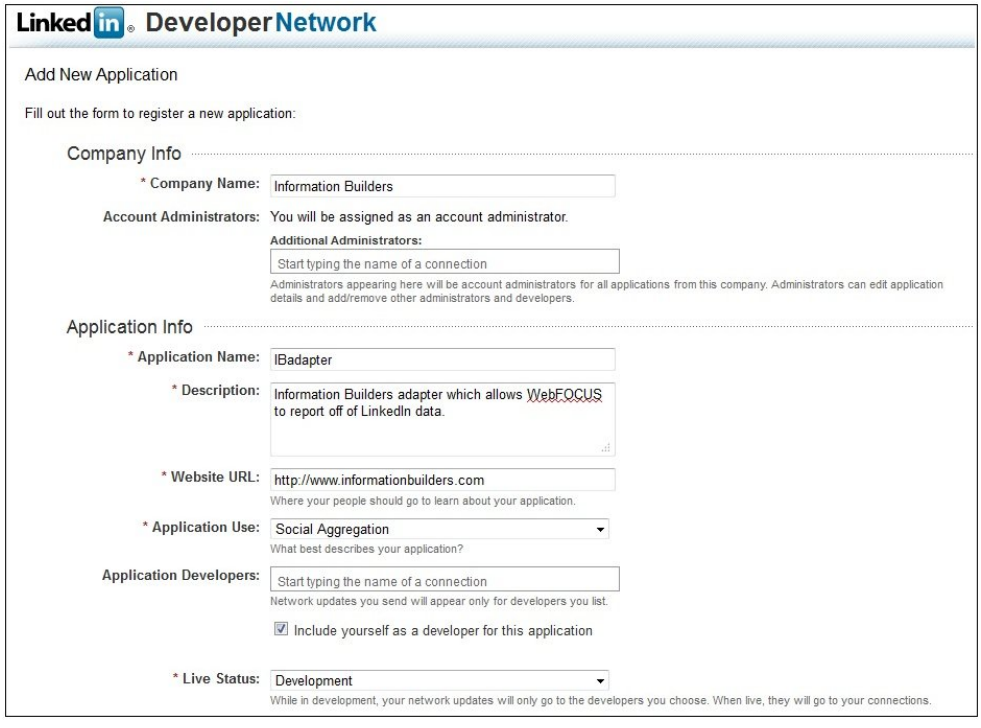


2. Enter the LinkedIn Sign in credentials and click *Sign In*.

   The LinkedIn Developer Network screen opens, as shown in the following image.

3. Click the *Add New Application* link.

The Add New Application screen opens, as shown in the following image.



4. Perform the following steps:

   a. Enter a company name hosting the new LinkedIn application in the Company Name field.

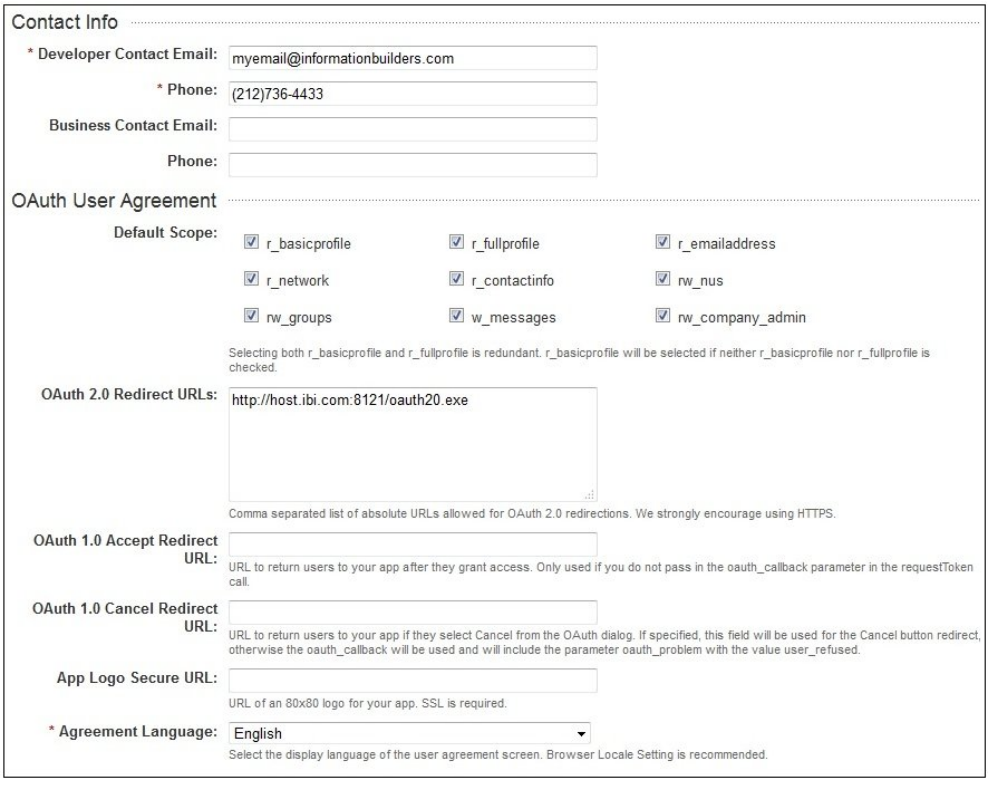
   b. Enter a name without spaces for the new LinkedIn application in the Application Name field.

   c. Enter a description for the new LinkedIn application in the Description field.

   d. Enter a web site URL for the company hosting the new LinkedIn application in the Website URL field.

   e. From the Application Use drop-down list, select a category which describes the use of the LinkedIn application.

5. Scroll down to the Contact Info section of the page, as shown in the following image.



6. Perform the following steps:

   a. Enter an email address for the LinkedIn application administrator in the Developer Contact Email field.

   b. Enter the telephone number for the LinkedIn application administrator in the Phone field.

   c. In the Default Scope section, check the permissions granted to the LinkedIn application.

   d. Enter the host name and port used to access the WebFOCUS Reporting Server Web Console with oauth20.exe in the OAuth 2.0 Redirect URLs field.

      For example:

      ```
      http://host.ibi.com:8121/oauth20.exe
      ```

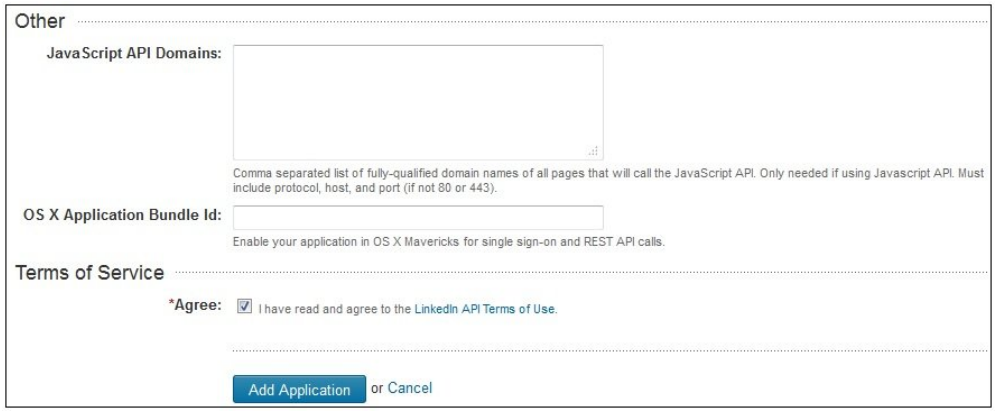
      If there are multiple WebFOCUS Reporting Servers used to access the LinkedIn application, separate each one of the OAuth 2.0 Redirect URLs with using a comma character (,).

For example:

```
http://host.ibi.com:8121/oauth20.exe,http://host2.ibi.com:8121/
oauth20.exe, http://localhost:8121/oauth20.exe
```

e. From the Agreement Language drop-down list, select the language to be used for the User Agreement screen.

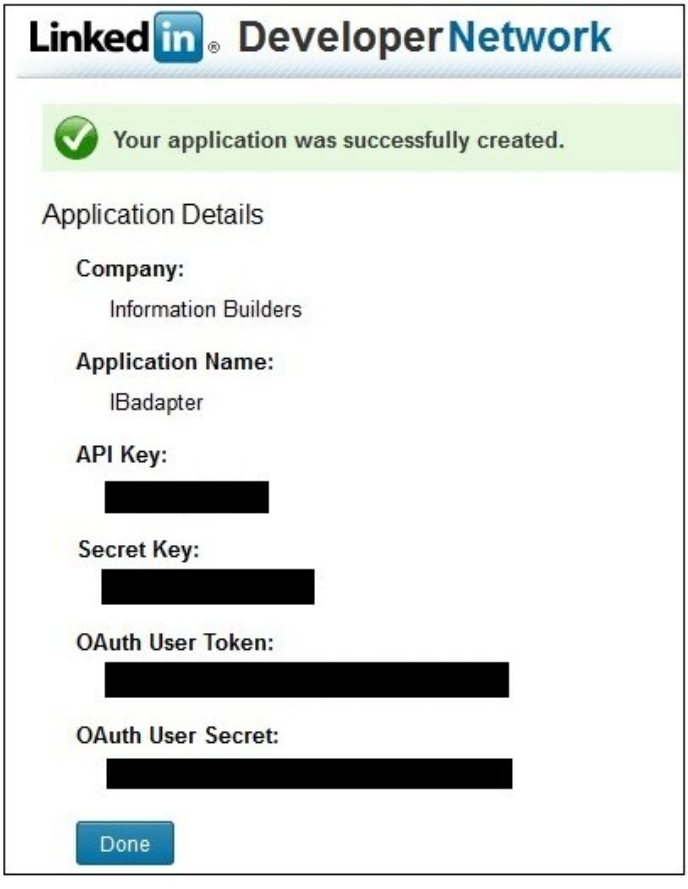
7. Scroll down to the Other section of the page, as shown in the following image.



8. Click the *LinkedIn API Terms of Use* link.

   If you accept the agreement, select *Agree* and then click *Add Application*.

The Application Details screen opens, as shown in the following image.



Note: The API Key and the Secret Key values will be required during the configuration of the LinkedIn adapter.

9. Click *Done*.

Configuring the LinkedIn Adapter

This section describes how to configure the LinkedIn Adapter.

Procedure: How to Configure the LinkedIn Adapter

1. Clear the cookies from the browser that will used to start the Reporting Server Web Console.

2. Access the WebFOCUS Reporting Server Web Console using the host name and port that you specified in the OAuth 2.0 Redirect URLs field of the LinkedIn application.

   For example:

   ```
   http://host.ibi.com:8121
   ```

   For more information on specifying values for the OAuth 2.0 Redirect URLs field, see *How to Create a LinkedIn Application* on page 1275.

3. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

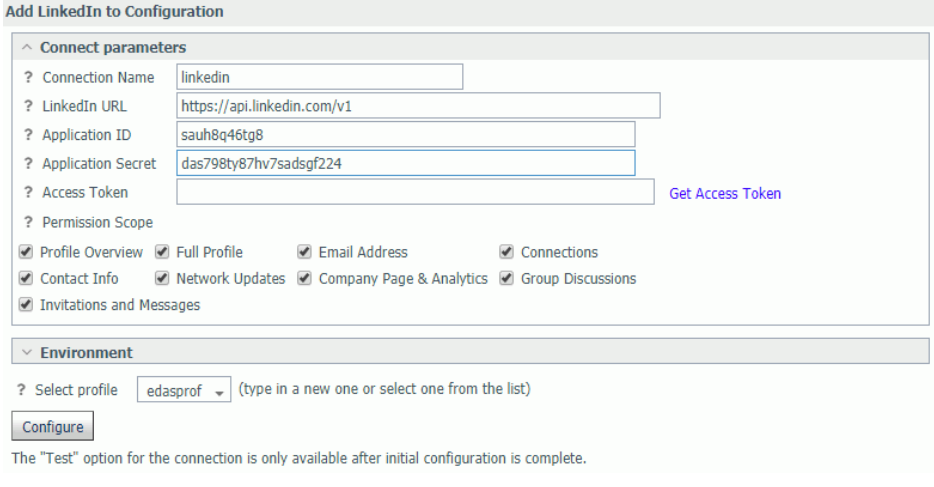
   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

4. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

5. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

6. Right-click the *LinkedIn* node and select *Configure*.

   The Add LinkedIn to Configuration pane opens, as shown in the following image.

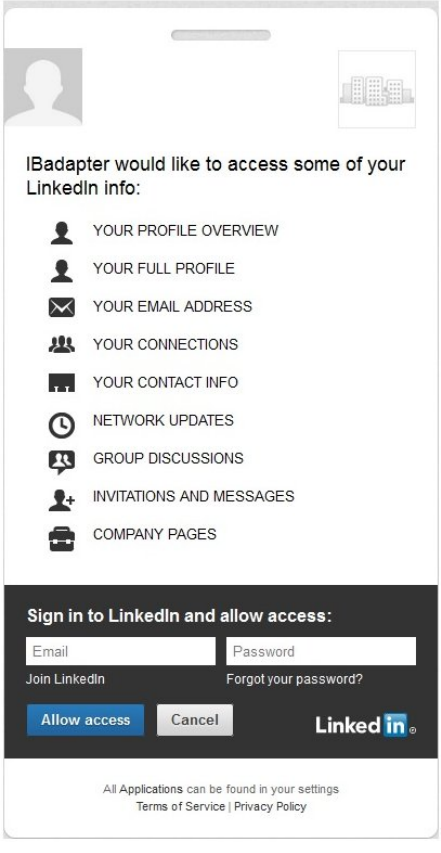


7. Enter the values for the Application ID and Application Secret as defined by the API Key and Secret Key respectively in the LinkedIn application.

   For more information, see *Creating a LinkedIn Application* on page 1275.

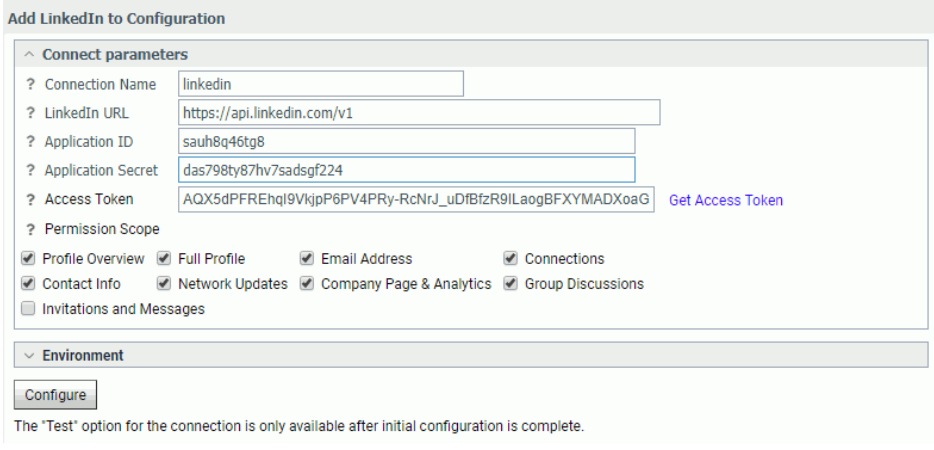
8. Choose the Permission Scope options to be granted to the LinkedIn application and click the *Get Access Token* link. For more information, see *Connection Attributes for LinkedIn* on page 1283.

   A LinkedIn Sign In page opens, as shown in the following image.



9. Enter the LinkedIn Sign In credentials and then click *Allow Access*.

You are returned to the Add LinkedIn to Configuration pane, where the Access Token field is now populated, as shown in the following image.



10. Click *Configure*.

    The LinkedIn adapter is added to the configured Adapters list in the navigation pane.

    Note: The Access Token expires after 60 days. To refresh the Access Token, click the *Get Access Token* link and then click *Configure*.

Reference: Connection Attributes for LinkedIn

The following list describes the connection attributes for the LinkedIn adapter.

Connection Name

Logical name used to identify this particular set of connection attributes. The default is CON01.

LinkedIn URL

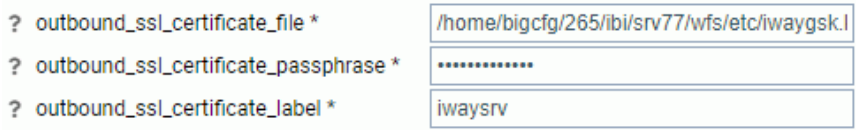
The URL of the LinkedIn API request. The default value is:

`https://api.linkedin.com/v1`

For iSeries machines, the WebFOCUS Reporting Server must be configured for SSL as follows:

1. From the Web Console sidebar, click *Workspace*.
2. From the menu bar, click *Workspace Set*, and select *Miscellaneous Settings*

3. Enter values for *outbound_ssl_certificate_file*, *outbound_ssl_certificate_passphrase*, and *outbound_ssl_certificate_label*, and then click *Save*. For example:



Application ID

The LinkedIn Application ID as defined in the LinkedIn application. For more information, see *Creating a LinkedIn Application* on page 1275.

Application Secret

The LinkedIn Application Secret as defined in the LinkedIn application. For more information, see *Creating a LinkedIn Application* on page 1275.

Access Token

Click the *Get Access Token* link to obtain this token. The credentials for a LinkedIn account are then entered. The value for the Access Token is returned by an authorized login.

Permission Scope

Grants the selected permissions to the LinkedIn application, which include:

- ❑ Profile Overview
- ❑ Full Profile
- ❑ Email Address
- ❑ Connections
- ❑ Contact Info
- ❑ Network Updates
- ❑ Company Page & Analytics
- ❑ Group Discussions
- ❑ Invitations and Messages

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the connection attributes. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (user.prf) or a group profile if available on your platform (using the appropriate naming convention), choose New Profile from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

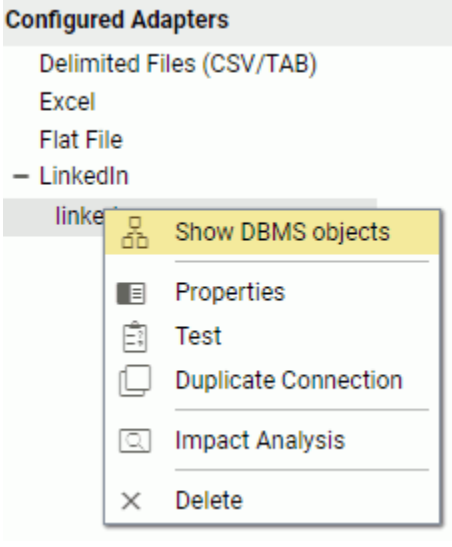
Store the connection attributes in the server profile (edasprof).

Creating Metadata and Sample Reports for the LinkedIn Adapter

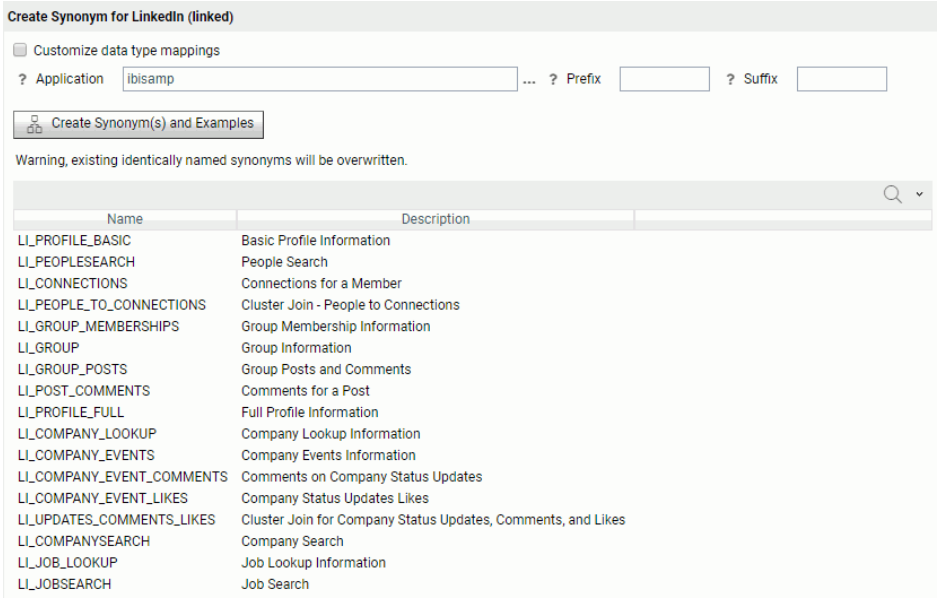
Create Synonym for the LinkedIn Adapter creates the metadata used for WebFOCUS reporting. It also creates sample WebFOCUS reports.

Procedure: How to Create Metadata and Sample Reports

1. From the WebFOCUS Reporting Server Web Console, expand the *Adapters* folder, *Configured* folder, and then the *LinkedIn* folder.
2. Right-click the configured connection for the LinkedIn Adapter (for example, linkedin) and select *Show DBMS objects* from the context menu, as shown in the following image.



The Create Synonym for LinkedIn pane opens, as shown in the following image.



3. Enter a specific application in the Application field or click the ellipsis button to the right of the field to select an application where the metadata and sample reports are to be stored.
4. Click *Create Synonym(s) and Examples*.

   The Create Synonym for LinkedIn Status pane opens and indicates that the synonym was created successfully.

LinkedIn Adapter Examples

This section describes the metadata and sample reports for the LinkedIn Adapter.

Reference: LinkedIn Adapter Metadata

The following table lists and describes the available metadata for the LinkedIn Adapter.

Metadata	Description
li_company_event_comments	Used to retrieve company event status updates and comments.
li_company_event_likes	Used to retrieve company event status update likes.

Metadata	Description
li_company_events	Used to retrieve a company's status updates and job postings.
li_company_lookup	Used to lookup a company profile.
li_companysearch	Used to search for companies based on keywords.
li_connections	Used to retrieve connections for a LinkedIn member.
li_group	Used to retrieve information about a specific group.
li_group_memberships	Used to retrieve a list of groups that a LinkedIn member has joined.
li_group_posts	Used to retrieve posts and comments for a specific group.
li_job_lookup	Used to lookup details for a specific job.
li_jobsearch	Used to search for jobs based on search criteria.
li_peoplesearch	Used to search for people based on search criteria.
li_post_comments	Used to retrieve comments for a specific group post.
li_profile_basic	Used to retrieve basic profile information for a LinkedIn member.
li_profile_full	Used to retrieve full profile information for the authenticated LinkedIn member.
lisampl/li_people_to_connections	Cluster Join from li_profile_basic to li_connections.

Metadata	Description
lisampl/li_updates_comments_likes	Cluster Join to report on company status updates, comments, and likes. Joins: ❑ li_company_events to li_company_event_comments ❑ li_company_events to li_company_event_likes

Reference: **LinkedIn Adapter Sample Reports**

The following table lists and describes the sample reports for the LinkedIn Adapter.

Sample Report	Description
lisampl/ li_company_event_comments	Reports on company events including comments. Uses: li_company_event_comments
lisampl/li_company_event_likes	Reports on the member likes for company status updates. Uses: li_company_event_likes
lisampl/li_company_events	Reports on company status updates and job postings for a specific company. Uses: li_company_events
lisampl/li_company_lookup	Retrieve information about a specific company. Uses: li_company_lookup

Sample Report	Description
lisampl/li_companysearch	Searches for companies based on keywords. Uses: li_companysearch
lisampl/li_connections	Lists the connections for a specific LinkedIn member. Uses: li_connections
lisampl/li_group	Displays the information about a specific group. Uses: li_group
lisampl/li_group_memberships	Lists the groups that a LinkedIn member has joined. Uses: li_group_memberships
lisampl/li_group_posts	Reports on posts including comments for a specific group. Uses: li_group_posts
lisampl/li_job_lookup	Displays information about a specific job. Usage requires approval from LinkedIn to Vetted API Access where the application form can be accessed from: *https://help.linkedin.com/app/api-dvr* Uses: li_job_lookup

Sample Report	Description
lisampl/li_jobsearch	Searches for jobs based on specific search criteria. Usage requires approval from LinkedIn to Vetted API Access where the application form can be accessed from: *https://help.linkedin.com/app/api-dvr* Uses: li_jobsearch
lisampl/li_people_to_connections	Lists the connections for a specific LinkedIn member. Includes name of the specific LinkedIn member. Uses: lisampl/li_people_to_connections
lisampl/li_peoplesearch	Search for people based on specific search criteria. Usage requires approval from LinkedIn to Vetted API Access where the application form can be accessed from: *https://help.linkedin.com/app/api-dvr* Uses: li_peoplesearch
lisampl/li_peoplesearch_facet	Performs a facet search based on specific search criteria. For example, location and industry. Usage requires approval from LinkedIn to Vetted API Access where the application form can be accessed from: *https://help.linkedin.com/app/api-dvr* Uses: li_peoplesearch_facet

Sample Report	Description
lisampl/li_post_comments	Reports on comments for a specific group post. Uses: li_post_comments
lisampl/li_profile_basic	Displays the basic profile information for a specific LinkedIn member. Uses: li_profile_basic
lisampl/li_profile_full	Displays the full profile information for the authenticated LinkedIn member. Uses: li_profile_full
lisampl/li_updates_comments_likes	Displays the status updates, comments and likes for a specific company. Uses: lisampl/li_updates_comments_likes

Chapter 53

Using the Adapter for Lotus Notes

Based on the native client API, the Adapter for Lotus Notes provides access to local Lotus Notes databases, including email databases, and remote Domino Server databases.

The adapter currently creates synonyms for documents based on forms, views, folders, and calendars, which are referred to collectively as objects in the remainder of this document.

In this chapter:

Preparing the Lotus Notes Environment

The Adapter for Lotus Notes accesses Domino databases using Java APIs, which are part of the Domino Designer package.

The adapter can access both local Lotus Notes databases and remote Domino Server databases:

- If, on a local computer, Lotus Notes Client or Domino Designer or Domino Server is installed, then you must include the Notes.jar file in the CLASSPATH.
- If the local computer does not have any Lotus Notes software installed and you wish to access remote Domino Server databases through the adapter, you must include an NCSO.jar file in the CLASSPATH.
- On a remote Domino server, CORBA-based remote (IIOP) APIs calls are employed. The local computer need not have Domino installed.

For related information, refer to your *Lotus Notes* documentation.

Procedure: How to Prepare the Lotus Notes Environment on Windows

Specify the location of the Lotus Notes .jar file in the CLASSPATH environment variable.

Procedure: How to Prepare the Lotus Notes Environment on UNIX

Specify the location of the Lotus Notes .jar file in the $CLASSPATH environment variable.

For example, if the files are located in /usr/driver_files, you would issue the following statements:

```
CLASSPATH=/usr/driver_files/NCSO.jar
export CLASSPATH
```

Alternatively, you could use the Web Console to specify the location:

1. From the menu bar's Workspace menu, select *Configuration/Monitor*.
2. Expand the *Java Services* folder.
3. Right-click *DEFAULT* and select *Properties* from the popup menu.

   The Java Services Configuration pane opens.
4. Select the *Class path* section.
5. Specify full path to the Lotus Notes .jar file in the *IBI_CLASSPATH* text field.
6. Click the *Save and Restart Java Services* button.

Configuring the Adapter for Lotus Notes

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to Lotus Notes, the adapter requires connection information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for Lotus Notes

The Lotus Notes adapter is under the *DBMS* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

Note: For a local database connection, this is the only required entry.

Domino Server host

The remote server name.

Port

Domino Server port for remote (IIOP) calls.

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

IBI_CLASSPATH

Defines the additional Java Class directories or full-path jar names which will be available for Java Services. Value may be set by editing the communications file or in the Web Console. Using the Web Console, you can enter one reference per line in the input field. When the file is saved, the entries are converted to a single string using colon (:) delimiters for all platforms. OpenVMS platforms must use UNIX-style conventions for values (for example, /mydisk/myhome/myclasses.jar, rather than mydisk:[myhome]myclasses.jar) when setting values. When editing the file manually, you must maintain the colon delimiter.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

Connection string for local database:

```
ENGINE LOTUS SET CONNECTION_ATTRIBUTES connection_name
```

Connection string for remote database:

```
ENGINE LOTUS SET CONNECTION_ATTRIBUTES connection_name
 Domino_server/user_ID,password: 'PORT port'
```

where:

connection_name

Is the logical name used to identify a particular set of attributes.

Note: For a local database connection, this is the only required entry.

Domino_server

Is the remote server name.

port

Is the Domino Server port for remote (IIOP) calls.

user_ID

Primary authorization ID by which you are known to Lotus Notes.

password

Password associated with the primary authorization ID.

Example: Declaring Connection Attributes

Connection string for local database:

```
ENGINE LOTUS SET CONNECTION_ATTRIBUTES CON2
```

Connection string for remote database:

```
ENGINE LOTUS SET CONNECTION_ATTRIBUTES CON1
ibilotus/SYSTEM,FEE21945C4B7942A:'PORT 63148'
```

Managing Lotus Notes Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the Lotus Notes data types.

Creating Synonyms

Synonyms define unique names (or aliases) for each Lotus Notes object that is accessible from the server. Synonyms are useful because they hide the underlying data source location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server metadata.

For the adapter to be able to create synonyms, Lotus Notes documents and data must be accessible to the HTTP client.

Procedure: How to Create a Synonym

To create a synonym, you must have previously configured the adapter. You can create a synonym from the Web Console or the Data Management Console.

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.
   - **Create metadata objects.** This opens the page for selecting synonym objects and properties.
   - **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
   - **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.
3. Enter values for the parameters required by the adapter as described in the synonym creation parameters reference.

   - *Synonym Creation Parameters for a Local Lotus Notes Database* on page 1299.
   - *Synonym Creation Parameters for a Remote Domino Database* on page 1302.
4. After entering the parameter values, click *Create Synonym*.

   The Status pane indicates that the synonym was created successfully.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the *Validate* check box, the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: **Synonym Creation Parameters for a Local Lotus Notes Database**

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Step 1

Select a database

Your previously specified connection information appears at the top of the pane. Notice that Domino Server host is indicated as <*local*>.

In the Local Database Full Name box, enter the name of the database you wish to use.

Specify Lotus Notes objects in the database

- By default object types are not restricted. If you wish to restrict them, deselect the corresponding check boxes.
- If you wish to retrieve all objects in the specified database, leave the *Filter by Name* box unchecked.
- If you wish to enter an object name or filter the objects list, check the *Filter by Name* box. A Name box opens in which you can specify a particular object or enter a string with wildcards as needed (for example, abc%, %abc, or %abc%) to limit the list of objects that will be displayed.

Complete Step 1 by clicking the *Next* button.

Step 2: Synonym field name processing options

Select options from this pane as needed.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Step 2 (continued): The objects retrieved from the database you selected in Step 1 are listed in the table at the bottom of the pane. You can now select objects to create synonym(s).

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Fixed Alpha Fields?

If this box is checked, all Lotus alpha fields are created as A*n*, where *n* is specified in the Alpha Field Size column.

If this box is unchecked, all Lotus alpha fields are created as A*n*V (the default), where *n* is specified in Alpha Field Size column.

Alpha Field Size

Displays the length of the alpha fields. The default length is 127. You can change this value. The generated Master File will reflect the chosen field length.

Database Name

Displays the name of the database that contains the selected objects.

Object Name

Lists the names of the objects for which you can generate synonyms. (The default synonym name is the same as the object name.)

Object Type

Indicates whether the object is a form, view, folder, or calendar.

Select Objects

Select objects for which you wish to create synonyms:

- To select all objects in the list, click the *Select All* button.
- To select specific objects, select the corresponding check boxes.

Restrict Object Type to

Restrict candidates for synonym creation based on the selected object type(s): Tables, Views, External SQL Scripts, and any other supported objects.

Choosing *External SQL Scripts* from the drop-down list enables you to represent an SQL Query as a synonym for read-only reporting. A Synonym candidate can be any file that contains one (and only one) valid SQL Query and does not contain end-of-statement delimiters (";" or "/") and comments.

Depending on the adapter, you can further restrict your search by choosing check boxes for listed objects.

Example: Creating a Synonym for a Form in a Local Lotus Notes Database

From the Web Console or the Data Management Console, right-click the configured Lotus Notes connection and choose *Create Synonym* from the menu. The first synonym creation pane opens:

1. In the Local Database Full Name entry box, type: *log.nsf*
2. For this example it is not necessary to filter objects, so simply click *Next*.
3. On the second pane, select *Mail_Events* from the list of forms and views, and click *Overwrite Existing Synonyms*.
4. Leave the Fixed Alpha Fields check box unchecked (the default) to create all Lotus alpha fields in the format A*n*V.
5. The alpha fields length in the next column is 127 by default. Use the default value for this example.

6. Click the *Create Synonym* button.

   The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: *Created successfully*

7. Click *Applications* on the menu bar.
8. Open the *baseapp* application folder in the navigation pane and click the synonym *Mail_Events*.
9. Choose *Edit as Text* from the menu to view the generated Master File, then choose *Edit Access File as Text* to view the corresponding Access File.

Generated Master File for Mail_Events form in the local log.nsf database

```
FILENAME=MAIL_EVENTS, SUFFIX=LOTUS    , $
  SEGMENT=MAIL_EVENTS, SEGTYPE=S0, $
    FIELDNAME=UNID, ALIAS=UNID_KEY, USAGE=A32, ACTUAL=A32, $
    FIELDNAME=BODY, ALIAS=Body, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
    FIELDNAME=FINISHTIME, ALIAS=FinishTime, USAGE=HYYMDs, ACTUAL=A17,
      MISSING=ON, $
    FIELDNAME=STARTTIME, ALIAS=StartTime, USAGE=HYYMDs, ACTUAL=A17,
      MISSING=ON, $
    FIELDNAME=SERVER, ALIAS=Server, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
```

Generated Access File

```
SEGNAME=MAIL_EVENTS, CONNECTION=CON3,DATABASE=log.nsf,OBJECT=Mail Events,
  OBJTYPE=FORM, KEYNAME=UNID_KEY, $
```

Reference: Synonym Creation Parameters for a Remote Domino Database

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Step 1

Specify databases

Your previously specified connection information appears at the top of the pane: Domino Server, port, and user ID. You can now specify the databases you want to retrieve from the remote Domino server.

- ❑ If you want to retrieve all databases, leave the box *Filter by Name* box unchecked.

- If you want to specify a database name or filter the list of retrieved databases, check the *Filter by Name* box. A Name box opens in which you can specify a particular database or enter one or more wildcards (for example, abc%, %abc, or %abc%) to limit the list of databases that will be displayed.

Complete Step 1 by clicking the *Next* button.

Step 2

Specify objects and the database that contains them

Your database filtering criterion appears at the top of the pane, and the list of databases that meet the criterion appears in a drop-down list at the bottom. In this step you specify a particular database and request retrieval of one, all, or a filtered list of the objects it contains.

- By default object types are not restricted. If you wish to restrict them, deselect the corresponding check boxes.
- If you wish to retrieve all objects in the selected database, leave the *Filter by Name* box unchecked.
- If you wish to specify an object name or filter the objects list, check the *Filter by Name* box. A Name box opens in which you can specify a particular object or enter one or more wildcards (for example, abc%, %abc, or %abc%) to limit the list of objects that will be displayed.
- If, in step 1, you requested a filtered list of databases or did not filter at all, you can now choose a specific database from the *Select Database* drop-down menu.

Complete Step 2 by clicking the *Next* button.

Synonym field name processing options (Step 3)

Select options from this pane, as needed.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

(Step 3 continued) The objects retrieved from the database you selected previously (either in step1 or step 2) are listed in the table at the bottom of the pane. You can now select objects to create synonym(s).

Default Synonym Name

This column displays the name that will be assigned to each synonym. To assign a different name, replace the displayed value.

Fixed Alpha Fields?

If this box is checked, all Lotus alpha fields are created as A*n*, where *n* is specified in the Alpha Field Size column.

If this box is unchecked, all Lotus alpha fields are created as A*n*V (the default), where *n* is specified in Alpha Field Size column.

Alpha Field Size

Displays the length of the alpha fields. The default length is 127. You can change this value when a synonym is created. The generated Master File will reflect the chosen field length.

Database Name

Displays the name of the database that contains the selected objects.

Object Name

Lists the names of the objects for which you can generate synonyms. (The default synonym name is the same as the object name.)

Object Type

Indicates whether the object is a form, view, folder, or calendar.

Select Objects

Select objects for which you wish to create synonyms:

- To select all objects in the list, click the *Select All* button.
- To select specific objects, select the corresponding check boxes.

Example: Creating a Synonym for a View in a Remote Domino Database

From the Web Console or the Data Management Console, right-click the configured Lotus Notes connection and choose Create Synonym from the menu. The first synonym creation pane opens:

1. Click the *Filter by Name* check box, type *certlog.nsf* in the Name entry box, and click the *Next* button. The second pane opens.
2. For this example, you will restrict objects to views, so leave only *Views* checked. Then click the *Next*button.
3. On the third pane, select the *By _User Name* view from the list of views, and click *Overwrite Existing Synonyms*.
4. Leave the Fixed Alpha Fields check box unchecked (the default) to create all Lotus alpha fields in the format A*n*V.
5. The alpha fields length in the next column is 127 by default. Use the default value for this example.
6. Click the *Create Synonym* button.

   The synonym is created and added under the specified application directory (baseapp is the default).

   A status window displays the message: Created successfully
7. Click *Applications* on the menu bar.
8. Open the *baseapp* application folder in the navigation pane and click the synonym *By_User_Name*.

9. Choose *Edit as Text* from the menu to view the generated Master File, then choose *Edit Access File as Text* to view the corresponding Access File.

Generated Master File for the By _User_Name view in the certlog.nsf database

```
FILENAME=BY_USER_NAME, SUFFIX=LOTUS    , $
  SEGMENT=BY_USER_NAME, SEGTYPE=S0, $
    FIELDNAME=USER_NAME, ALIAS=1, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
    FIELDNAME=LICENSE, ALIAS=2, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
    FIELDNAME=NOT_VALID_BEFORE, ALIAS=3, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
    FIELDNAME=CERTIFIER, ALIAS=4, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
    FIELDNAME=NOT_VALID_AFTER, ALIAS=5, USAGE=A127V, ACTUAL=A127V,
      MISSING=ON, $
```

Generated Access File

```
SEGNAME=BY__USER_NAME, CONNECTION=CON1, DATABASE=certlog.nsf,
  OBJECT=By_User Name, OBJTYPE=VIEW, $
```

Reference: Universal Note ID for Forms

A UNID field is automatically added to Master Files generated for Forms.

The Universal Note ID (UNID) identifies all copies of a note, regardless of location or time.

As a result, every replica of the note has the same UNID, which does not change when a note is modified.

(This field is illustrated in *Creating a Synonym for a Form in a Local Lotus Notes Database* on page 1301.)

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Reference: Access File Keywords

Keyword	Description
SEGNAME	Value must be identical to the SEGNAME value in the Master File.

Keyword	Description
CONNECTION	Indicates access to the previously declared connection. The syntax is: CONNECTION=*connection*
DATABASE	Identifies the Lotus Notes database file.
OBJECT	Specifies the name of a Lotus Notes object.
OBJTYPE	Indicates the type of Lotus Notes object: FORM, VIEW, FOLDER, or CALENDAR.

Data Type Support

The following table indicates how the server maps Lotus Notes data types.

Lotus Notes Data Type	USAGE	ACTUAL	Remarks
Text Dialog List Checkbox Radio Button List Box Combo Box Authors Names Readers Password Formula	A*n*V | A*n*	A*n*V | A*n*	*n* is specified by user (default is 127).
Date/Time	HYYMDs	A17	
Number	D16	D8	

Lotus Notes Data Type	USAGE	ACTUAL	Remarks
Rich Text			BLOB (Binary Large Object) format is supported as a component of the Rich Text data type, which is used to distribute e-mail attachments. The attachment portion uses the BLOB format in the Master File. BLOB format is supported through the Reporting Server API. For an illustration, see *Mapping the Rich Text Data Type* on page 1308.

Example: **Mapping the Rich Text Data Type**

Rich text fields are used for large amounts of text or to embed or attach objects. For example, the Body field on a mail form is a rich text field that is mapped to three fields in the following Master File

```
FIELDNAME=BODY_ATTACHMENT, ALIAS=Body_ATTACHMENT, USAGE=BLOB, ACTUAL=BLOB,
  MISSING=ON, $
FIELDNAME=BODY_FNAME, ALIAS=Body_IZHBOPIA, USAGE=A256, ACTUAL=A256,
  MISSING=ON, $
FIELDNAME=BODY, ALIAS=Body, USAGE=A25V, ACTUAL=A25V,MISSING=ON, $
```

where:

`BODY_ATTACHMENT`

Is a BLOB field used to store the attachment. BLOB format is supported through the Reporting Server API.

`BODY_FNAME`

Is the file name of the original attachment.

`BODY`

Is the text in the field. For large amounts of text, you can manually modify the USAGE and ACTUAL lengths in the Master File.

Note: Formatted text, another common use of the rich text data type, is *not* currently supported by the adapter.

Chapter 54

Using the Adapter for LDAP

The Adapter for LDAP (Lightweight Directory Access Protocol) allows applications to access LDAP data sources. The adapter converts data or application requests into native LDAP statements and returns optimized answer sets to the requesting program.

This is a read-only adapter. Information Builders currently supports the following vendors: Sun, IBM, Novell, Microsoft, and OpenLDAP. Some vendors provide libraries that are available natively with the operating system and do not require installation. Some vendor libraries have to be installed.

Since the Adapter for LDAP operates at the protocol level, Information Builders recommends using the client that is native to the operating system. It is marked as preferred on the configuration page. There is no need to match the vendor of the LDAP server with the vendor of the LDAP client.

In this chapter:

Preparing the LDAP Environment

Before you can create an LDAP synonym, you must:

- **Install LDAP vendor's libraries.** For details, see *LDAP Vendor Library Prerequisites* in the Web Console help system (expand the *Server Administration* folder, then open the *Security* topic and choose *Security LDAP)*

Configuring the Adapter for LDAP

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

In order to connect to LDAP, the adapter requires connection information. You supply this information using the SET CONNECTION_ATTRIBUTES command. You can:

- Enter connection and authentication information in the Web Console or the Data Management Console configuration panes. The consoles add the command to the profile you select: the global server profile (edasprof.prf), a user profile (*user.prf*), or a group profile (if supported on your platform).
- Manually add the command in the global server profile (edasprof.prf), in a user profile (*user.prf)*, or in a group profile (if supported on your platform).

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.
2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.
3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.
4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.
5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.
6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for LDAP

The LDAP adapter in under the *DBMS* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

LDAP Vendor

Name of the LDAP vendor: Sun, IBM, Novell, Microsoft.

LDAP Host

Address of the host machine on which the LDAP server is located.

Port

The LDAP server uses two different ports, one for regular connections (the default is 389); the other is for SSL connections (the default is 636).

To connect to LDAP through the SSL connection (secure connection), enter an LDAP port that is specifically configured by LDAP to accept SSL connections.

Secure Connection

This configuration parameter indicates an SSL/TLS connection to the LDAP server.

Security

There are two authentication methods when connecting to an LDAP server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the LDAP server at connection time for authentication.
- **Trusted.** The adapter connects to the LDAP server using anonymous bind.

User DN

User Distinguished Name, the unique identifier for an object in the LDAP Directory utilized as the primary authorization ID.

Password

Password associated with the primary authorization ID.

SSL Certificate

This option applies only if an ldap_secure_connection has been set to use a Secure Socket Layer (SSL) session with the LDAP server.

Enter the name of the LDAP attribute used by the API to establish the SSL/TLS connection. The API can be one of the following:

`Novell API, OpenLDAP API`

Specifies the file name (including path) of the Trusted Root Certificate that the LDAP server provides for authentication.

`Sun/Netscape API`

Specifies the path to cert7.db (Netscape certificate database excluding the file name) that the LDAP server provides for authentication.

`IBM API`

Specifies file name (including path) of the ldapkey.kdb (IBM key database file) that the LDAP server provides for authentication. (Note that the ldapkey.sth password stash file must be in the same directory.)

SSL Certificate Encryption

For Novell only, in the *ldap_ssl_certificate_encoding* field select the standard used to encode the certificate from the drop-down list. The options are:

`B64`

`DER`

Note that encryption and file format depend on API vendor specifications.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

```
ENGINE X500IN SET CONNECTION_ATTRIBUTES conn_name ldap_server_url/
['user_dn'[,password]]:'PORT ldap_server_port_number
[SSLCERT ssl_certificate SSLCERTENC ssl_certificate_encoding]'
```

where:

`x500IN`

Is the suffix for the Adapter for LDAP.

conn_name

Is a logical name used to identify this particular set of attributes.

ldap_server_url

Is the address of the host machine on which the LDAP server is located.

user_dn

Is the User Distinguished Name, a unique identifier for an object in LDAP Directory utilized as the primary authorization ID.

password

Is the password associated with the primary authorization ID.

ldap_server_port_number

Is the LDAP server port number. (The SSL port should be used for the secure connection.)

ssl_certificate

Is the location of the SSL certificate file.

ssl_certificate_encoding

SSL certificate file encoding.

Note: UDNBASE and UDNATTRIBUTE are required for the Explicit security. Otherwise, they are ignored.

Example: Declaring Connection Attributes

```
ENGINE X500IN SET CONNECTION_ATTRIBUTES CON02 edasol29/
'uid=pgmavv,ou=iway,dc=ibi,dc=com',CD25FFDBB91B6790:'PORT 389'
```

Managing LDAP Metadata

When the server accesses a data source, it needs to know how to interpret the data stored there. For each data source the server will access, you create a synonym that describes the structure of the data source and the server mapping of the LDAP data types.

Mapping Server Metadata and LDAP Schema Definitions

Server metadata is generated from the LDAP schema, which is stored on the LDAP server in a partition separate from the partitions that contain directory objects (which are treated as reported data objects).

Each directory object in the LDAP tree is addressable using a Distinguished Name (DN), which contains the root path from the object up.

The schema defines set of rules that govern the types of objects that can exist in a tree. Each object belongs to an object class that specifies which attributes can be associated with the object. All attributes are based on a set of attribute types that are, in turn, based on a standard set of attribute syntaxes. The schema controls the structure of individual objects as well as the relationships among the objects in the tree. Schema rules allow some objects to contain other, subordinate objects. Thus, the schema gives structure to the tree.

The schema consists of two basic components:

- **Object classes.** An Object class is a set of rules that determines what attributes can be contained in the directory object (entry).
- **Attribute types.** Attribute type is a set of data types called attribute syntaxes. The attribute syntaxes define the data types for values stored in the attribute.

Although LDAP can support many attribute syntaxes (data types), the Adapter for LDAP currently supports only the String data type.

Supported Object class rules are:

- **SUP.** Superior object class (parent).
- **MUST.** Required attributes (fields).
- **MAY.** Optional attributes (fields with MISSING=ON).

An LDAP Entry is the actual data item (object or node) that comprises the LDAP tree. Each entry holds Attributes, which are *key=value* pairs in which the key can have more than one value. Multi-value attributes are the default. Single-value attributes are denoted with the SINGLE-VALUE keyword in the attributeTypes attribute in the schema.

Server metadata describes a subset of the LDAP tree, starting with the DN passed down to the leaf hierarchical level when a synonym is created. The provided root DN is stored in the Access File.

The Server metadata represents each object in the processed LDAP hierarchy as a segment (whose name is taken from the Object class name), with fields (that are created out of the object attributes).

Master File	LDAP Schema
Segment name	Object class name
Field name	Adjusted Attribute name
Alias	Unadjusted Attribute name
Fields with MISSING=ON	Optional Attributes

The default USAGE and ACTUAL formats are set as A64 unless the size of an attribute is specified by the schema.

Creating Synonyms

Synonyms define unique names (or aliases) for each LDAP table or view that is accessible from the server. Synonyms are useful because they hide the underlying data source's location and identity from client applications. They also provide support for extended metadata features of the server, such as virtual fields and additional security mechanisms.

Using synonyms allows an object to be moved or renamed while allowing client applications to continue functioning without modification. The only modification required is a redefinition of the synonym on the server. The result of creating a synonym is a Master File and an Access File, which represent the server's metadata.

Procedure: How to Create a Synonym

1. From the Web Console *Applications* page, click *Get Data*.
2. On the Configured Adapters section of the page, in Simple Mode, right-click an adapter and click *Show Connections*. Right-click a connection.

   Depending on the type of adapter you chose, one of the following options appears on the context menu.

   - **Show DBMS objects.** This opens the page for selecting synonym objects and properties.

- **Create metadata objects.** This opens the page for selecting synonym objects and properties.
- **Show files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show local files.** This opens a file picker. After you choose a file of the correct type, the page for selecting synonym objects and properties opens.
- **Show topics.** This opens the page for selecting synonym objects and properties for topics within the Kafka environment.

3. Enter values for the parameters required by the adapter as described in the chapter for your adapter.
4. After entering the parameter values, click *Add*.

   The button may be labeled *Next*, *Create Synonym*, *Create Base Synonyms*, *Create Cluster Synonym*, or *Update Base Synonyms*.

   The synonym creation process for most adapters has been consolidated so that you can enter all necessary parameters on one page. However, for some adapters such as LDAP, you must click *Next* buttons until you get to a page that has a *Create Synonym* button.

The synonym is created and added under the specified application directory.

Note: When creating a synonym, if you choose the Validate check box (where available), the server adjusts special characters and checks for reserved words. For more information, see *Validation for Special Characters and Reserved Words* on page 2743.

Reference: Synonym Creation Parameters for LDAP

The following list describes the parameters for which you will need to supply values, and related tasks you will need to complete in order to create a synonym for the adapter. These options may appear on multiple panes. To advance from pane to pane, click the buttons provided, ending with the *Create Synonym* button, which generates the synonym based on your entries.

Processing Modes are SCHEMA FLAT, SCHEMA HIERARCHY, and LDIF:

SCHEMA FLAT

Builds a synonym ignoring the LDAP data tree hierarchy, and produces a Master File with a single segment.

SCHEMA HIERARCHY

Builds a synonym reflecting the LDAP data tree hierarchy supporting two levels of the data tree (root and child), and produces a Master File by mapping selected object classes to segments.

LDIF

Builds a synonym reflecting the complete hierarchy of the LDAP data tree and produces a multisegmented Master File.

Filter by Object Class name

Creates a subset of Object Classes so that only a small list of Object Classes is produced.

Set as Index

Indicates the attribute (field) that can be utilized as the sort attribute for the LDAP API.

Note: Only a single attribute can be used as an Index.

View referenced Object names

Produces a list of Object Classes related by inheritance to the one selected.

Note: Adding referenced Object(s) is optional.

Base DN

- **For SCHEMA FLAT:** Is the Distinguished Name (DN) of the LDAP tree entry (node) that is set as a default root for data retrieval.

  Note: While Base DN is optional at the Create Synonym step, it is required for data retrieval, and can be provided in TABLE requests as:

  ```
  IF BASEDN EQ 'dc=ibi,dc=com'
  ```

  Note: Range retrieval is supported. When range retrieval is to be utilized, it is necessary to set Base DN to the leaf object containing attributes with the description utilized for retrieval. It is the DN of the group when retrieving a list of group members via range retrieval.

- **For LDIF:** Is the Distinguished Name (DN) of the LDAP tree entry (node) from which the synonym is created.

Synonym name

Displays the name that will be assigned to the synonyms. To assign a different name, replace the displayed value.

Model DN

Distinguished Name that the adapter uses to retrieve list of attributes. It can be any valid DN of the LDAP tree. For example:

```
uid=pgmtst5,ou=iway,dc=ibi,dc=com
```

or

```
ou=iway,dc=ibi,dc=com
```

By default, it is root DSE:

```
dc=ibi,dc=com
```

If this step skipped, all the attributes in the schema are fetched to the list.

Select attributes

Optional attribute selection that allows the user to specify the list of attributes (fields) that are present in the synonym. The user can reduce the size of the Master File by omitting unnecessary attributes.

If this step is skipped, all schema attributes will be present in the synonym.

Note that if all attributes are selected, the effect is the same as if no attributes are selected. For example, all available attributes in the schema will be present in the synonym.

Validate

Select the *Validate* check box if you wish to convert all special characters to underscores and perform a name check to prevent the use of reserved names. (This is accomplished by adding numbers to the names.) This parameter ensures that names adhere to specifications. See *Validation for Special Characters and Reserved Words* on page 2743 for more information.

When the Validate option is unchecked, only the following characters are converted to underscores: '-'; ' '; ' \'; '/'; ','; '$'. No checking is performed for names.

Make unique

Select the *Make unique* check box if you wish to set the scope for field and group names to the entire synonym. This ensures that no duplicate names are used, even in different segments of the synonym. When this option is unchecked, the scope is the segment.

Application

Select an application directory. The default value is baseapp.

Prefix/Suffix

If you have tables with identical table names, assign a prefix or a suffix to distinguish them. For example, if you have identically named human resources and payroll tables, assign the prefix HR to distinguish the synonyms for the human resources tables. Note that the resulting synonym name cannot exceed 64 characters.

If all tables and views have unique names, leave the prefix and suffix fields blank.

Overwrite Existing Synonyms

To specify that this synonym should overwrite any earlier synonym with the same fully qualified name, select the *Overwrite existing synonyms* check box.

Note: The connected user must have operating system write privileges in order to recreate a synonym.

Reference: Guidelines for Manually Editing an LDAP Master File

If you wish to delete non-essential information from a generated synonym, you can manually edit the Master File using the following editing guidelines:

- **Technique 1.** If you wish to remove individual fields from a Master File segment and other fields in that segment that are not essential to your work, remove the entire segment from the Master File.
- **Techniques 2.** If you wish to remove individual fields from a Master File segment but require other fields in that segment, note the following before editing the file:
  - You must preserve any fields referenced in the Access File in the format RDN=*fieldname*.

    The attribute name RDN is part of the group of attributes that comprise an LDAP entry. This field is part of the DN, and, as such, is always activated during data retrieval and must be included in the Master File.
  - As long as you retain the RDN attribute, you can delete other non-essential fields from the Master File.

Reference: Managing Synonyms

Once you have created a synonym, you can right-click the synonym name in the Adapter navigation pane of either the Web Console or the Data Management Console to access the available options.

For a list of options, see *Synonym Management Options* on page 93.

Chapter 55

Using the Adapter for MariaDB

The Adapter for MariaDB allows applications to access MariaDB data sources. The adapter converts application requests into native MariaDB statements and returns optimized answer sets to the requesting application.

In this chapter:

Preparing the MariaDB Environment

The Adapter for MariaDB requires the MariaDB Connector/J JDBC driver.

In order to report against Unicode data in MariaDB, you must enable Unicode support in the reporting server. For more information, see *MySQL and Unicode* on page 1635.

Procedure: How to Prepare the MariaDB Environment on Windows

1. Specify the location of the MariaDB Connector/JDBC driver files in the CLASSPATH environment variable. You must specify the full location and name of the jar file. For example, if the jar file is located in C:\Program Files\MariaDB\JDBC Driver, then specify:

   ```
   CLASSPATH= C:\Program Files\MariaDB\JDBC Driver/mariadb-java-
   client-1.5.3.jar.
   ```

2. Specify the location of the Javarun time environment or development kit in the JAVA_HOME or JDK_HOME environment variable. Either is acceptable.

   You must specify the location where the run time environment is installed. You should see a sub-directory bin in that directory. For example, if you have the run time environment in C:\Program Files\java\jre7 then specify:

   ```
   JAVA_HOME=C:\Program Files\java\jre7
   ```

   Alternately, if you have the full development kit installed in C:\Program Files\java \jdk1.7.0_05, then specify:

```
JDK_HOME= C:\Program Files\java\jdk1.7.0_05
```

3. Start (or restart) the server.

Note: You also need to restart the server if the driver has changed.

Procedure: How to Prepare the MariaDB Environment on UNIX

Specify the location of several files:

1. Specify the location of the MariaDB Connector/JDBC driver files in the $CLASSPATH environment variable.

   For example, if the files are located in /usr/driver_files, you would issue the following statements:

   ```
   CLASSPATH=/usr/driver_files/mydriver.jar;$CLASSPATH
   export CLASSPATH
   ```

   To ensure that the variable is set before server startup, add the CLASSPATH setting in your UNIX profile.

   Alternatively, you could use the Web Console to specify the location:

   a. From the Workspace menu, select *Java Services*.
   b. Right-click *DEFAULT*, and select *Properties*.

      The Java Services Configuration pane opens.
   c. Select the *Class path* section.
   d. Specify the full path to the MariaDB Connector/J jar file in the IBI_CLASSPATH field.
   e. Click *Save and Restart Java Services*.

2. Specify the location of the Java Development Kit's installation directory in the $JDK_HOME environment variable.

   For example, if you want to set the location of the Java Development Kit to /usr/java, you would issue the following statements:

   ```
   JDK_HOME=/usr/java
   export JDK_HOME
   ```

3. Specify the location of the Java Virtual Machine's installation directory in the $LD_LIBRARY_PATH environment variable.

   For example, if you want to set the location of the JVM to /usr/j2sdk1.7.0_05/jre/lib/i386/server, you would issue the following statements:

   ```
   LD_LIBRARY_PATH=/usr/j2sdk1.7.0_05/jre/lib/i386/server
   export LD_LIBRARY_PATH
   ```

Note that if the server is running with security on, the LD_LIBRARY_PATH variable is ignored. In this case, you must use IBI_LIBPATH.

4. Start (or restart) the server.

Note: You also need to restart the server if the driver has changed.

MariaDB and Unicode

The Adapter for MariaDB is implemented using JDBC. This implementation supports Unicode data stored in character fields with the CHARACTER SET set to UTF-8.

You must set the LANG environment variable in the edastart file or in a separate shell file before you start the server. For example, for American English you would export the following variable:

```
export LANG=EN_US.UTF-8
```

For details, see *Unicode Support* in the *Server Administration* manual.

Configuring the Adapter for MariaDB

Configuring the adapter consists of specifying connection and authentication information for each of the connections you want to establish.

Declaring Connection Attributes

The SET CONNECTION_ATTRIBUTES command allows you to declare a connection to one MariaDB database server and to supply authentication attributes necessary to connect to the server.

You can declare connections to more than one MariaDB database server by issuing multiple SET CONNECTION_ATTRIBUTES commands. The actual connection takes place when the first query referencing that connection is issued (see *Overriding the Default Connection* on page 1640). You can include SET CONNECTION_ATTRIBUTES commands in an RPC or a server profile. The profile can be encrypted.

If you issue multiple SET CONNECTION_ATTRIBUTES commands:

- The *first* SET CONNECTION_ATTRIBUTES command sets the default MariaDB database server to be used.
- If more than one SET CONNECTION_ATTRIBUTES command declares the same MariaDB database server, the authentication information is taken from the *last* SET CONNECTION_ATTRIBUTES command.

Procedure: How to Configure an Adapter

1. From the Web Console Applications page, click *Get Data*.

   or

   From the Data Management Console, expand the *Adapters* folder.

   In the DMC, the Adapters folder opens. In the Web Console, the Get Data page opens showing your configured adapters.

2. In the Web Console, click the *(+)* button, and find the adapter on the page or, in the DMC, expand the *Available* folder if it is not already expanded.
   On the Web Console, you can select a category of adapter from the drop-down list or use the search option (magnifying glass) to search for specific characters.

3. In the DMC, expand the appropriate group folder and the specific adapter folder. The group folder is described in the connection attributes reference.

4. Right-click the adapter name and/or version and select *Configure*.

   The Add Adapter to Configuration pane opens.

5. Enter values for the parameters required by the adapter, as described in the chapter for the specific adapter you want to configure.

6. Click *Configure*. The configured adapter is added to the Adapters list in the DMC resources tree or the Configured list in the Web Console.
   In the Web Console, the adapter remains on the Available Adapters list with an asterisk to indicate that at least one connection has been configured. You can configure additional connections from either the Configured or Available list by right-clicking the adapter and clicking *Add Connection*.

Reference: Connection Attributes for MariaDB

The MariaDB adapter is under the *SQL* group folder.

The following list describes the connection attributes for which you can supply values. To complete the attribute declaration, click the *Configure* button.

Connection name

Logical name used to identify this particular set of connection attributes. The default is CON01.

URL

Enter the location URL for the MariaDB data source. The basic syntax is

```
jdbc:MariaDB://host:port/database
```

where:

host:*port*

Is the computer name or IP address and port on which the MariaDB database is located.

database

Is the name of the database.

These are two examples:

```
jdbc:MariaDB://localhost/qatst
```

```
jdbc:MariaDB://<host>:<port>/qatst
```

You can reference additional MariaDB connection properties in the URL. If you wish to do so, follow these guidelines: in the URL the first property must be preceded by the ? character, and the second and subsequent properties referenced in the URL must be preceded by the & character followed immediately by an | character, as illustrated in the following example.

Suppose that you wish to add the following connection properties:

```
sessionVariables=sql_mode=PIPES_AS_CONCAT
 zeroDateTimeBehavior=convertToNull
```

Enter the URL as follows:

```
jdbc:MariaDB://host/database?sessionVariables=sql_mode=P
IPES_AS_CONCAT&|
 zeroDateTimeBehavior=convertToNull
```

Note: The URL must be entered as a single line, without a space after the | character.

Driver name

Name of the Microsoft JDBC driver: `org.mariadb.jdbc.Driver`

Security

There are two methods by which a user can be authenticated when connecting to a database server:

- **Explicit.** The user ID and password are explicitly specified for each connection and passed to the database, at connection time, for authentication.
- **Password Passthru.** The user ID and password received from the client application are passed to the database, at connection time, for authentication.

User

Primary authorization ID by which you are known to the data source.

Password

Password associated with the primary authorization ID.

Select profile

Select a profile from the drop-down menu to indicate the level of profile in which to store the CONNECTION_ATTRIBUTES command. The global profile, edasprof.prf, is the default.

If you wish to create a new profile, either a user profile (*user*.prf) or a group profile if available on your platform (using the appropriate naming convention), choose *New Profile* from the drop-down menu and enter a name in the Profile Name field (the extension is added automatically).

Store the connection attributes in the server profile (edasprof).

Syntax: How to Declare Connection Attributes Manually

For explicit authentication:

```
ENGINE SQLMAR SET CONNECTION_ATTRIBUTES [connection]/userid,password
```

For password passthru authentication:

```
ENGINE SQLMAR SET CONNECTION_ATTRIBUTES connection/
```

where:

`SQLMAR`

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

`connection`

The name of the connection. You can give any name to the connection that you want.

`userid`

Is the primary authorization ID by which you are known to MariaDB.

`password`

Is the password associated with the primary authorization ID.

Example: **Declaring Connection Attributes**

The following SET CONNECTION_ATTRIBUTES command connects to the MariaDB database server named TEST with an explicit user ID and password:

```
ENGINE SQLMAR SET CONNECTION_ATTRIBUTES TEST/USERA,PWDA
```

The following SET CONNECTION_ATTRIBUTES command connects to the MariaDB database server named TEST using password passthru authentication:

```
ENGINE SQLMAR SET CONNECTION_ATTRIBUTES TEST/
```

Authenticating a User

There are two methods by which a user can be authenticated when connecting to a MariaDB database server:

- **Explicit.** User IDs and passwords are explicitly stated in SET CONNECTION_ATTRIBUTES commands. You can include these commands in the server global profile, edasprof.prf, for all users.
- **Database or Password Passthru.** User ID and password received from the client application are passed to the MariaDB database server for authentication.

When a client connects to the server, the user ID and password are passed to MariaDB for authentication and are not authenticated by the server. To implement this type of authentication, start the server with security turned off. The server allows the client connection, and then stores an encrypted form of the client connection message to be used for connection to a MariaDB database server at anytime during the lifetime of the server agent.

Overriding the Default Connection

Once all MariaDB connections to be accessed have been declared using the SET CONNECTION_ATTRIBUTES command, there are two ways to select a specific MariaDB connection from the list of declared connections:

- You can select a default connection using the SET DEFAULT_CONNECTION command. If you do not issue this command, the connection name value specified in the *first* SET CONNECTION_ATTRIBUTES command is used.
- You can include the CONNECTION= attribute in the Access File of the table specified in the current SQL query. When you include a connection name in the CREATE SYNONYM command from the Web Console, the CONNECTION= attribute is automatically included in the Access File. This attribute supersedes the default connection.

Syntax: How to Select a Connection to Access

```
ENGINE SQLMAR SET DEFAULT_CONNECTION [connection]
```

where:

SQLMAR

Indicates the adapter. You can omit this value if you previously issued the SET SQLENGINE command.

connection

Is the connection name specified in a previously issued SET CONNECTION_ATTRIBUTES command. If omitted, then the local database server will be set as the default. If this connection name has not been previously declared, a FOC1671 message is issued.

Note:

- If you use the SET DEFAULT_CONNECTION command more than once, the connection name specified in the last command will be the active connection name.
- The SET DEFAULT_CONNECTION command cannot be issued while an uncommitted transaction (LUW) is pending. In that case, a FOC1671 message is issued.

Example: Selecting a Connection to Access

The following SET DEFAULT_CONNECTION command selects the MariaDB database server named TNSNAMEB as the default MariaDB database server:

```
ENGINE SQLMAR SET DEFAULT_CONNECTION datasource_name
```
