Release 7710
Contents

Preface ........................................................................ 13

Conventions .......................................................................... 15
Related Publications ................................................................ 16
Customer Support .................................................................. 16
Information You Should Have .......................................................... 17
User Feedback ...................................................................... 18
iWay Software Training and Professional Services ........................................ 18

1. Functions Overview ........................................................... 19

Function Arguments .................................................................. 19
Function Categories .................................................................. 20
Character Chart for ASCII and EBCDIC .................................................. 20

2. Simplified Analytic Functions ................................................. 29

FORECAST_MOVAVE: Using a Simple Moving Average ........................................... 29
FORECAST_EXPAVE: Using Single Exponential Smoothing ..................................... 35
FORECAST_DOUBLEXP: Using Double Exponential Smoothing ................................. 38
FORECAST_SEASONAL: Using Triple Exponential Smoothing .................................. 40
FORECAST_LINEAR: Using a Linear Regression Equation .................................. 45
PARTITION_AGGR: Creating Rolling Calculations .......................................... 48
PARTITION_REF: Using Prior or Subsequent Field Values in Calculations ..................... 58
INCREMENT: Calculating the Difference Between the Current and a Prior Value of a Field ........ 62
PCT_INCREMENT: Calculating the Percentage Difference Between the Current and a Prior Value of a Field ........................................................................ 66
PREVIOUS: Retrieving a Prior Value of a Field ............................................ 69
RUNNING_AVE: Calculating an Average Over a Group of Rows .............................. 71
RUNNING_MAX: Calculating a Maximum Over a Group of Rows ............................. 74
RUNNING_MIN: Calculating a Minimum Over a Group of Rows ............................. 77
RUNNING_SUM: Calculating a Sum Over a Group of Rows ................................. 80

3. Simplified Character Functions ................................................ 83

CHAR_LENGTH: Returning the Length in Characters of a String .................................. 84
CONCAT: Concatenating Strings .................................................................. 84
DIGITS: Converting a Number to a Character String .................................................. 85

Functions Reference
5. Variable Length Character Functions ........................................ 139
   Overview ............................................................................. 139
   LENV: Returning the Length of an Alphanumeric Field ................. 140
   LOCASV: Creating a Variable Length Lowercase String ................. 140
   POSITV: Finding the Beginning of a Variable Length Substring ....... 141
   SUBSTV: Extracting a Variable Length Substring ......................... 143
   TRIMV: Removing Characters From a String ............................... 144
   UPCASV: Creating a Variable Length Uppercase String ................. 145

6. Character Functions for DBCS Code Pages .............................. 147
   DCTRAN: Translating A Single-Byte or Double-Byte Character to Another .... 147
   DEDIT: Extracting or Adding Characters .................................. 148
   DSTRIP: Removing a Single-Byte or Double-Byte Character From a String . 150
   DSUBSTR: Extracting a Substring .......................................... 151
   JPTRANS: Converting Japanese Specific Characters ...................... 152
KKFCUT: Truncating a String .............................................................. 157
SFTDEL: Deleting the Shift Code From DBCS Data ............................... 158
SFTINS: Inserting the Shift Code Into DBCS Data .................................. 159

7. Data Source and Decoding Functions ........................................... 161
   CHECKMD5: Computing an MD5 Hash Check Value ............................ 161
   CHECKSUM: Computing a Hash Sum ............................................... 162
   COALESCE: Returning the First Non-Missing Value ........................... 163
   DB_EXPR: Inserting an SQL Expression Into a Request ........................... 163
   DB_INFILE: Testing Values Against a File or an SQL Subquery ............... 165
   DB_LOOKUP: Retrieving Data Source Values ..................................... 170
   DECODE: Decoding Values .......................................................... 172
   FIND: Verifying the Existence of a Value in a Data Source .................... 173
   IMPUTE: Replacing Missing Values With Aggregated Values .................... 175
   LAST: Retrieving the Preceding Value ......................................... 180
   LOOKUP: Retrieving a Value From a Cross-referenced Data Source ............. 181
   NULLIF: Returning a Null Value When Parameters Are Equal ................... 183

8. Simplified Date and Date-Time Functions ..................................... 185
   DT_CURRENT_DATE: Returning the Current Date ............................... 186
   DT_CURRENT_DATETIME: Returning the Current Date and Time ................. 186
   DT_CURRENT_TIME: Returning the Current Time ................................ 187
   DTADD: Incrementing a Date or Date-Time Component ........................... 187
   DTDIFF: Returning the Number of Component Boundaries Between Date or Date-Time Values 189
   DTIME: Extracting Time Components From a Date-Time Value .................. 190
   DTPART: Returning a Date or Date-Time Component in Integer Format ........ 191
   DTRUNC: Returning the Start of a Date Period for a Given Date ............... 192

9. Date Functions .............................................................. 195
   Overview of Date Functions ..................................................... 196
   Using Standard Date Functions .................................................. 196
      Specifying Work Days ......................................................... 197
      Specifying Business Days .................................................. 197
      Specifying Holidays ......................................................... 198
   Enabling Leading Zeros For Date and Time Functions in Dialogue Manager .... 202
DATEADD: Adding or Subtracting a Date Unit to or From a Date ................................................................. 203
DATECVT: Converting the Format of a Date ........................................................................................................... 205
DATEDIFF: Finding the Difference Between Two Dates .......................................................................................... 207
DATEMOV: Moving a Date to a Significant Point ................................................................................................. 209
DATETRAN: Formatting Dates in International Formats .......................................................................................... 214
FIYR: Obtaining the Financial Year ...................................................................................................................... 230
FIQTR: Obtaining the Financial Quarter ................................................................................................................ 232
FIYYQ: Converting a Calendar Date to a Financial Date ..................................................................................... 234
TODAY: Returning the Current Date ...................................................................................................................... 235
Using Legacy Date Functions .................................................................................................................................. 236
   Using Old Versions of Legacy Date Functions .................................................................................................. 237
AYMD: Adding or Subtracting Days ......................................................................................................................... 237
CHGDAT: Changing How a Date String Displays ..................................................................................................... 238
DA Functions: Converting a Legacy Date to an Integer .......................................................................................... 241
DMY, MDY, YMD: Calculating the Difference Between Two Dates ........................................................................ 242
DOWK and DOWKL: Finding the Day of the Week ............................................................................................. 242
DT Functions: Converting an Integer to a Date ........................................................................................................ 243
GREGDT: Converting From Julian to Gregorian Format ...................................................................................... 244
JULDAT: Converting From Gregorian to Julian Format .......................................................................................... 245
YM: Calculating Elapsed Months ............................................................................................................................ 246

10. Date-Time Functions ........................................................................................................................................... 249
   Using Date-Time Functions .................................................................................................................................. 250
   Date-Time Parameters .......................................................................................................................................... 250
      Specifying the Order of Date Components ........................................................................................................ 250
      Specifying the First Day of the Week for Use in Date-Time Functions ................................................................. 251
      Controlling Processing of Date-Time Values ...................................................................................................... 253
   Supplying Arguments for Date-Time Functions .................................................................................................... 253
   HADD: Incrementing a Date-Time Value ................................................................................................................. 255
   HCNVRT: Converting a Date-Time Value to Alphanumeric Format .................................................................... 257
   HDATE: Converting the Date Portion of a Date-Time Value to a Date Format .................................................... 258
   HDIFF: Finding the Number of Units Between Two Date-Time Values ................................................................. 258
   HDTTM: Converting a Date Value to a Date-Time Value ...................................................................................... 260
HGETC: Storing the Current Local Date and Time in a Date-Time Field ...................... 261
HGETZ: Storing the Current Coordinated Universal Time in a Date-Time Field ................ 262
HHMMSS: Retrieving the Current Time ................................................ 263
HHMS: Converting a Date-Time Value to a Time Value ................................... 264
HINPUT: Converting an Alphanumeric String to a Date-Time Value .......................... 265
HMIDNT: Setting the Time Portion of a Date-Time Value to Midnight ....................... 266
HNAME: Retrieving a Date-Time Component in Alphanumeric Format ....................... 267
HPART: Retrieving a Date-Time Component as a Numeric Value ........................... 267
HSETPT: Inserting a Component Into a Date-Time Value .................................. 268
HTIME: Converting the Time Portion of a Date-Time Value to a Number ................... 269
HTMTOTS: Converting a Time to a Timestamp .......................................... 270
HYYWD: Returning the Year and Week Number From a Date-Time Value ...................... 271

11. Simplified Conversion Functions .................................................................. 273
CHAR: Returning a Character Based on a Numeric Code ................................. 273
COMPACTFORMAT: Displaying Numbers in an Abbreviated Format ...................... 274
CTRLCHAR: Returning a Non-Printable Control Character ................................. 275
FPRINT: Displaying a Value in a Specified Format ....................................... 276
HEXTYPE: Returning the Hexadecimal View of an Input Value ............................. 277
PHONETIC: Returning a Phonetic Key for a String ....................................... 278
TO_INTEGER: Converting a Character String to an Integer Value ........................... 279
TO_NUMBER: Converting a Character String to a Numeric Value ........................... 279

12. Format Conversion Functions ...................................................................... 281
ATODBL: Converting an Alphanumeric String to Double-Precision Format .......... 281
EDIT: Converting the Format of a Field ......................................................... 282
FPRINT: Converting Fields to Alphanumeric Format ...................................... 283
FTOA: Converting a Number to Alphanumeric Format .................................... 284
HEXBYT: Converting a Decimal Integer to a Character .................................. 285
ITONUM: Converting a Large Number to Double-Precision Format .................... 287
ITOPACK: Converting a Large Binary Integer to Packed-Decimal Format .......... 288
ITOZ: Converting a Number to Zoned Format ........................................... 289
PCKOUT: Writing a Packed Number of Variable Length ................................ 290
PTOA: Converting a Packed-Decimal Number to Alphanumeric Format .......... 291
13. Simplified Numeric Functions ............................................... 295
    CEILING: Returning the Smallest Integer Value Greater Than or Equal to a Value .......... 295
    EXPONENT: Raising e to a Power ........................................... 296
    FLOOR: Returning the Largest Integer Less Than or Equal to a Value .................... 296
    MOD: Calculating the Remainder From a Division ......................................... 297
    POWER: Raising a Value to a Power ............................................ 297

14. Numeric Functions ............................................................. 299
    ABS: Calculating Absolute Value ............................................. 299
    CHKPKCK: Validating a Packed Field ......................................... 300
    DMOD, FMOD, and IMOD: Calculating the Remainder From a Division ..................... 301
    EXP: Raising e to the Nth Power ............................................... 302
    EXPN: Evaluating a Number in Scientific Notation ....................................... 303
    INT: Finding the Greatest Integer ............................................ 304
    LOG: Calculating the Natural Logarithm ......................................... 305
    MAX and MIN: Finding the Maximum or Minimum Value ..................................... 305
    NORMSDST and NORMSINV: Calculating Normal Distributions ............................... 306
        NORMSDST: Calculating Standard Cumulative Normal Distribution ................. 306
        NORMSINV: Calculating Inverse Cumulative Normal Distribution ................... 309
    PRDNOR and PRDUNI: Generating Reproducible Random Numbers .......................... 310
    RDNORM and RDUNIF: Generating Random Numbers ........................................ 311
    SQRT: Calculating the Square Root ............................................. 311

15. Simplified Statistical Functions ........................................... 313
    Specify the Partition Size for Simplified Statistical Functions ......................... 313
    CORRELATION: Calculating the Degree of Correlation Between Two Sets of Data ........ 314
    KMEANS_CLUSTER: Partitioning Observations Into Clusters Based on the Nearest Mean Value ................................................................. 314
    MULTIREGRESS: Creating a Multivariate Linear Regression Column ...................... 317
    OUTLIER: Identifying Outliers in Numeric Data .......................................... 319
    RSERVE: Running an R Script .................................................... 321
16. Simplified System Functions .......................................................... 329

   EDAPRINT: Inserting a Custom Message in the EDAPRINT Log File .............. 329
   ENCRYPT: Encrypting a Password ..................................................... 330
   GETENV: Retrieving the Value of an Environment Variable ......................... 330
   PUTENV: Assigning a Value to an Environment Variable ............................ 331
   SLACK: Posting a Message to a Slack Channel ...................................... 332

17. System Functions ........................................................................... 335

   CLSDDREC: Closing All Files Opened by the PUTDDREC Function ............... 335
   FEXERR: Retrieving an Error Message ................................................ 336
   FGETENV: Retrieving the Value of an Environment Variable ....................... 337
   FPUTENV: Assigning a Value to an Environment Variable ........................... 337
   GETUSER: Retrieving a User ID ......................................................... 339
   JOBNAME: Retrieving the Current Process Identification String .................... 339
   PUTDDREC: Writing a Character String as a Record in a Sequential File ........ 341
   SLEEP: Suspending Execution for a Given Number of Seconds ...................... 342
   SYSVAR: Retrieving the Value of a z/OS System Variable ............................ 343

18. Simplified Geography Functions .................................................... 345

   Sample Geography Files ........................................................................ 346
   GIS_DISTANCE: Calculating the Distance Between Geometry Points .............. 350
   GIS_DRIVE_ROUTE: Calculating the Driving Directions Between Geometry Points .. 352
   GIS_GEOCODE_ADDR: Geocoding a Complete Address ................................ 354
   GIS_GEOCODE_ADDR_CITY: Geocoding an Address Line, City, and State ......... 355
   GIS_GEOCODE_ADDR_POSTAL: Geocoding an Address Line and Postal Code .... 357
   GIS_GEOMETRY: Building a JSON Geometry Object .................................... 358
   GIS_IN_POLYGON: Determining if a Point is in a Complex Polygon ............... 360
   GIS_LINE: Building a JSON Line ........................................................ 362
   GIS_POINT: Building a Geometry Point ................................................ 364
   GIS_REVERSE_COORDINATE: Returning a Geographic Component ............... 366
   GIS_SERVICE_AREA: Calculating a Geometry Area Around a Given Point ....... 367
   GIS_SERV_AREA_XY: Calculating a Service Area Around a Given Coordinate .... 369

19. SQL Character Functions ............................................................... 373
<table>
<thead>

### Contents

22. SQL Numeric Functions .......................................................... 403

- **ABS:** Returning an Absolute Value (SQL) ........................................ 403
- **CEIL:** Returning the Smallest Integer Greater Than or Equal to a Value ... 404
- **FLOOR:** Returning the Largest Integer Less Than or Equal to a Value (SQL) ... 404
- **GREATEST:** Returning the Largest Value ....................................... 405
- **LEAST:** Returning the Smallest Value .......................................... 406
- **LOG:** Returning a Logarithm (SQL) ............................................. 407
- **EXP:** Returning e Raised to a Power ........................................... 407
- **MOD:** Returning the Remainder of a Division .................................... 408
- **POWER:** Raising a Value to a Power (SQL) ..................................... 408
- **SQRT:** Returning a Square Root (SQL) .......................................... 409

23. SQL Miscellaneous Functions ................................................... 411

- **COUNTBY:** Incrementing Column Values Row by Row ....................... 411
- **DB_EXPR:** Inserting an SQL Expression Into a Request (SQL) ............... 412
- **HEX:** Converting to Hexadecimal ............................................... 413
- **IF:** Testing a Condition ............................................................ 414
- **LENGTH:** Obtaining the Physical Length of a Data Item .................... 415
- **VALUE:** Coalescing Data Values ................................................. 415

24. SQL Operators .............................................................. 417

- **CASE:** SQL Case Operator ........................................................... 417
- **COALESCE:** Coalescing Data Values ............................................ 419
- **NULLIF:** NULLIF Operator .......................................................... 420

DATE: Converting to a Date .................................................................. 398
DECIMAL: Converting to Decimal Format ............................................ 398
FLOAT: Converting to Floating Point Format ..................................... 399
INT: Converting to an Integer ..................................................... 400
SMALLINT: Converting to a Small Integer ....................................... 400
TIME: Converting to a Time ....................................................... 401
TIMESTAMP: Converting to a Timestamp ......................................... 402

ABS: Returning an Absolute Value (SQL) .............................................. 403
CEIL: Returning the Smallest Integer Greater Than or Equal to a Value ........ 404
FLOOR: Returning the Largest Integer Less Than or Equal to a Value (SQL) ... 404
GREATEST: Returning the Largest Value ........................................... 405
LEAST: Returning the Smallest Value ............................................. 406
LOG: Returning a Logarithm (SQL) .................................................. 407
EXP: Returning e Raised to a Power ................................................ 407
MOD: Returning the Remainder of a Division ...................................... 408
POWER: Raising a Value to a Power (SQL) ....................................... 408
SQRT: Returning a Square Root (SQL) ............................................ 409

COUNTBY: Incrementing Column Values Row by Row ....................... 411
DB_EXPR: Inserting an SQL Expression Into a Request (SQL) ............... 412
HEX: Converting to Hexadecimal .................................................. 413
IF: Testing a Condition .............................................................. 414
LENGTH: Obtaining the Physical Length of a Data Item .................... 415
VALUE: Coalescing Data Values ................................................. 415
CASE: SQL Case Operator ........................................................... 417
COALESCE: Coalescing Data Values ............................................ 419
NULLIF: NULLIF Operator .......................................................... 420
This content describes how to use Information Builders-supplied functions to perform complex calculations and manipulate data in procedures. It is intended for application developers and end users.

How This Manual Is Organized

This manual includes the following chapters:

<table>
<thead>
<tr>
<th>Chapter/Appendix</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Functions Overview</td>
</tr>
<tr>
<td>2</td>
<td>Simplified Analytic Functions</td>
</tr>
<tr>
<td>3</td>
<td>Simplified Character Functions</td>
</tr>
<tr>
<td>4</td>
<td>Character Functions</td>
</tr>
<tr>
<td>5</td>
<td>Variable Length Character Functions</td>
</tr>
<tr>
<td>6</td>
<td>Character Functions for DBCS Code Pages</td>
</tr>
<tr>
<td>7</td>
<td>Data Source and Decoding Functions</td>
</tr>
<tr>
<td>8</td>
<td>Simplified Date and Date-Time Functions</td>
</tr>
<tr>
<td>9</td>
<td>Date Functions</td>
</tr>
</tbody>
</table>

Functions Reference
<table>
<thead>
<tr>
<th>Chapter/Appendix</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 Date-Time Functions</td>
<td>Describes date-time functions that manipulate date-time values.</td>
</tr>
<tr>
<td>11 Simplified Conversion Functions</td>
<td>Describes conversion functions that have streamlined parameter lists, similar to those used by SQL functions.</td>
</tr>
<tr>
<td>12 Format Conversion Functions</td>
<td>Describes format conversion functions that convert fields from one format to another.</td>
</tr>
<tr>
<td>13 Simplified Numeric Functions</td>
<td>Describes numeric functions that have streamlined parameter lists, similar to those used by SQL functions.</td>
</tr>
<tr>
<td>14 Numeric Functions</td>
<td>Describes numeric functions that perform calculations on numeric constants and fields.</td>
</tr>
<tr>
<td>15 Simplified Statistical Functions</td>
<td>Describes functions that perform statistical calculations.</td>
</tr>
<tr>
<td>16 Simplified System Functions</td>
<td>Describes system functions that have streamlined parameter lists, similar to those used by SQL functions.</td>
</tr>
<tr>
<td>17 System Functions</td>
<td>Describes system functions that call the operating system to obtain information about the operating environment or to use a system service.</td>
</tr>
<tr>
<td>18 Simplified Geography Functions</td>
<td>Describes geography functions that have streamlined parameter lists, similar to those used by SQL functions.</td>
</tr>
<tr>
<td>19 SQL Character Functions</td>
<td>Describes SQL character functions which manipulate alphanumeric fields and character strings.</td>
</tr>
<tr>
<td>20 SQL Date and Time Functions</td>
<td>Describes SQL date and time functions which manipulate date and time values.</td>
</tr>
<tr>
<td>21 SQL Data Type Conversion Functions</td>
<td>Describes SQL format conversion functions which convert fields from one format to another.</td>
</tr>
<tr>
<td>Chapter/Appendix</td>
<td>Contents</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------</td>

<td>SQL Miscellaneous Functions</td>
</tr>
<tr>
<td>24</td>
<td>SQL Operators</td>
</tr>
</tbody>
</table>

**Conventions**

The following table describes the conventions that are used in this manual.

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>THIS TYPEFACE</td>
<td>Denotes syntax that you must enter exactly as shown.</td>
</tr>
<tr>
<td>or this typeface</td>
<td></td>
</tr>
<tr>
<td>this typeface</td>
<td>Represents a placeholder (or variable) in syntax for a value that you or the system must supply.</td>
</tr>
<tr>
<td>underscore</td>
<td>Indicates a default setting.</td>
</tr>
<tr>
<td>this typeface</td>
<td>Represents a placeholder (or variable), a cross-reference, or an important term. It may also indicate a button, menu item, or dialog box option that you can click or select.</td>
</tr>
<tr>
<td>Key + Key</td>
<td>Indicates keys that you must press simultaneously.</td>
</tr>
<tr>
<td>{ }</td>
<td>Indicates two or three choices. Type one of them, not the braces.</td>
</tr>
<tr>
<td>[ ]</td>
<td>Indicates a group of optional parameters. None are required, but you may select one of them. Type only the parameter in the brackets, not the brackets.</td>
</tr>
<tr>
<td></td>
<td>Separates mutually exclusive choices in syntax. Type one of them, not the symbol.</td>
</tr>
<tr>
<td>Convention</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>...</td>
<td>Indicates that you can enter a parameter multiple times. Type only the parameter, not the ellipsis (...).</td>
</tr>
<tr>
<td>.</td>
<td>Indicates that there are (or could be) intervening or additional commands.</td>
</tr>
</tbody>
</table>

Customer Support

Do you have any questions about this product?

Join the Focal Point community. Focal Point is our online developer center and more than a message board. It is an interactive network of more than 3,000 developers from almost every profession and industry, collaborating on solutions and sharing tips and techniques. Access Focal Point at [http://forums.informationbuilders.com/eve/forums](http://forums.informationbuilders.com/eve/forums).

You can also access support services electronically, 24 hours a day, with InfoResponse Online. InfoResponse Online is accessible through our website, [http://www.informationbuilders.com](http://www.informationbuilders.com). It connects you to the tracking system and known-problem database at the Information Builders support center. Registered users can open, update, and view the status of cases in the tracking system and read descriptions of reported software issues. New users can register immediately for this service. The technical support section of [www.informationbuilders.com](http://www.informationbuilders.com) also provides usage techniques, diagnostic tips, and answers to frequently asked questions.

Call Information Builders Customer Support Services (CSS) at (800) 736-6130 or (212) 736-6130. Customer Support Consultants are available Monday through Friday between 8:00 a.m. and 8:00 p.m. EST to address all your questions. Information Builders consultants can also give you general guidance regarding product capabilities. Please be ready to provide your six-digit site code number (xxxx.xx) when you call.

To learn about the full range of available support services, ask your Information Builders representative about InfoResponse Online, or call (800) 969-INFO.
Information You Should Have

To help our consultants answer your questions most effectively, be ready to provide the following information when you call:

- Your six-digit site code (xxxx.xx).
- Your iWay Software configuration:
  - The iWay Software version and release. You can find your server version and release using the Version option in the Web Console.
    
    **Note:** the MVS and VM servers do not use the Web Console.
  - The communications protocol (for example, TCP/IP or LU6.2), including vendor and release.
  - The stored procedure (preferably with line numbers) or SQL statements being used in server access.
- The database server release level.
- The database name and release level.
- The Master File and Access File.
- The exact nature of the problem:
  - Are the results or the format incorrect? Are the text or calculations missing or misplaced?
  - Provide the error message and return code, if applicable.
  - Is this related to any other problem?
  - Has the procedure or query ever worked in its present form? Has it been changed recently? How often does the problem occur?
  - What release of the operating system are you using? Has it, your security system, communications protocol, or front-end software changed?
  - Is this problem reproducible? If so, how?
  - Have you tried to reproduce your problem in the simplest form possible? For example, if you are having problems joining two data sources, have you tried executing a query containing just the code to access the data source?
Do you have a trace file?

How is the problem affecting your business? Is it halting development or production? Do you just have questions about functionality or documentation?

User Feedback

In an effort to produce effective documentation, the Technical Content Management staff welcomes your opinions regarding this document. You can contact us through our website http://documentation.informationbuilders.com/connections.asp.

Thank you, in advance, for your comments.

iWay Software Training and Professional Services

Interested in training? Our Education Department offers a wide variety of training courses for iWay Software and other Information Builders products.

For information on course descriptions, locations, and dates, or to register for classes, visit our website (http://education.informationbuilders.com) or call (800) 969-INFO to speak to an Education Representative.

Interested in technical assistance for your implementation? Our Professional Services department provides expert design, systems architecture, implementation, and project management services for all your business integration projects. For information, visit our website (http://www.informationbuilders.com/support).
Functions Overview

Functions provide a convenient way to perform certain calculations and manipulations. They operate on one or more arguments and return a single value that is assigned to an `output_format`. The returned value can be stored in a field, assigned to a Dialogue Manager variable, used in an expression or other processing, or used in a selection or validation test. These functions can be used in source and target objects.

In this chapter:

- Function Arguments
- Function Categories
- Character Chart for ASCII and EBCDIC

Function Arguments

All function arguments except the last one are *input arguments*. The formats for these arguments are described with each function. Unless specified, every input argument can be provided as one of the following:

- A literal (that is, a number for numeric formats or a character string enclosed in single quotation marks for alphanumeric formats).
- A field of the correct format.
- A variable assigned by a Dialogue Manager command.
- An expression result evaluated in the correct format.

The `output` argument is the last function argument. With few exceptions, it is a required argument whose only goal is to provide a format for the output of a function. It is *not* a field to put the result in. The format can be provided as either:

- A character string enclosed in single quotation marks.
- A field name whose format is to be used.

This field is the one to which the result of the expression evaluation is assigned. If the `output_format` is alphanumeric, its size should be large enough to fit the function output and avoid truncation; excessive size causes the output to be padded with blanks.
**Note:** With CDN ON, numeric function arguments must be delimited by a comma followed by a space.

**Function Categories**

Functions are grouped into the following areas:

- **Character Functions**
- **Variable Length Character Functions**
- **Character Functions for DBCS Code Pages**
- **Data Source and Decoding Functions**
- **Date Functions**
  - **Using Standard Date Functions**
  - **Using Legacy Date Functions**
- **Date-Time Functions**
- **Format Conversion Functions**
- **Numeric Functions**
- **System Functions**

**Character Chart for ASCII and EBCDIC**

This chart shows the primary printable characters in the ASCII and EBCDIC character sets and their decimal equivalents. Extended ASCII codes (above 127) are not included.

Chapter 2

Simplified Analytic Functions

The analytic functions enable you to perform calculations and retrievals using multiple rows in the internal matrix.

In this chapter:

- **FORECAST_MOVAVE**: Using a Simple Moving Average
- **FORECAST_EXPAVE**: Using Single Exponential Smoothing
- **FORECAST_DOUBLEXP**: Using Double Exponential Smoothing
- **FORECAST_SEASONAL**: Using Triple Exponential Smoothing
- **FORECAST_LINEAR**: Using a Linear Regression Equation
- **PARTITION_AGGR**: Creating Rolling Calculations
- **PARTITION_REF**: Using Prior or Subsequent Field Values in Calculations
- **INCREASE**: Calculating the Difference Between the Current and a Prior Value of a Field
- **PCT_INCREASE**: Calculating the Percentage Difference Between the Current and a Prior Value of a Field
- **PREVIOUS**: Retrieving a Prior Value of a Field
- **RUNNING_AVE**: Calculating an Average Over a Group of Rows
- **RUNNING_MAX**: Calculating a Maximum Over a Group of Rows
- **RUNNING_MIN**: Calculating a Minimum Over a Group of Rows
- **RUNNING_SUM**: Calculating a Sum Over a Group of Rows

**FORECAST_MOVAVE: Using a Simple Moving Average**

A simple moving average is a series of arithmetic means calculated with a specified number of values from a field. Each new mean in the series is calculated by dropping the first value used in the prior calculation, and adding the next data value to the calculation.

Simple moving averages are sometimes used to analyze trends in stock prices over time. In this scenario, the average is calculated using a specified number of periods of stock prices. A disadvantage to this indicator is that because it drops the oldest values from the calculation as it moves on, it loses its memory over time. Also, mean values are distorted by extreme highs and lows, since this method gives equal weight to each point.
Predicted values beyond the range of the data values are calculated using a moving average that treats the calculated trend values as new data points.

The first complete moving average occurs at the $n^{th}$ data point because the calculation requires $n$ values. This is called the lag. The moving average values for the lag rows are calculated as follows: the first value in the moving average column is equal to the first data value, the second value in the moving average column is the average of the first two data values, and so on until the $n^{th}$ row, at which point there are enough values to calculate the moving average with the number of values specified.

### Syntax: How to Calculate a Simple Moving Average Column

```
FORECAST_MOVAVE(display, infield, interval, npredict, npoint1)
```

where:

- **display**
  - Keyword
  - Specifies which values to display for rows of output that represent existing data. Valid values are:
    - **INPUT_FIELD.** This displays the original field values for rows that represent existing data.
    - **MODEL_DATA.** This displays the calculated values for rows that represent existing data.

  **Note:** You can show both types of output for any field by creating two independent COMPUTE commands in the same request, each with a different display option.

- **infield**
  - Is any numeric field. It can be the same field as the result field, or a different field. It cannot be a date-time field or a numeric field with date display options.

- **interval**
  - Is the increment to add to each sort field value (after the last data point) to create the next value. This must be a positive integer. To sort in descending order, use the BY HIGHEST phrase. The result of adding this number to the sort field values is converted to the same format as the sort field.

  For date fields, the minimal component in the format determines how the number is interpreted. For example, if the format is YMD, MDY, or DMY, an interval value of 2 is interpreted as meaning two days. If the format is YM, the 2 is interpreted as meaning two months.
**n predict**

Is the number of predictions for FORECAST to calculate. It must be an integer greater than or equal to zero. Zero indicates that you do not want predictions, and is only supported with a non-recursive FORECAST.

**npoint**

Is the number of values to average for the MOVAVE method.

**Example:** Calculating a New Simple Moving Average Column

This request defines an integer value named PERIOD to use as the independent variable for the moving average. It predicts three periods of values beyond the range of the retrieved data. The MOVAVE column on the report output shows the calculated moving average numbers for existing data points.

```
DEFINE FILE GGSALES
SDATE/YYM = DATE;
SYEAR/Y = SDATE;
SMONTH/M = SDATE;
PERIOD/I2 = SMONTH;
END
TABLE FILE GGSALES
SUM UNITS DOLLARS
COMPUTE MOVAVE/D10.1= FORECAST_MOVAVE(MODEL_DATA, DOLLARS,1,3,3);
BY CATEGORY BY PERIOD
WHERE SYEAR EQ 97 AND CATEGORY NE 'Gifts'
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is:

<table>
<thead>
<tr>

</tbody>
</table>

In the report, the number of values to use in the average is 3 and there are no UNITS or DOLLARS values for the generated PERIOD values.

Each average (MOVAVE value) is computed using DOLLARS values where they exist. The calculation of the moving average begins in the following way:

- The first MOVAVE value (801,123.0) is equal to the first DOLLARS value.
The second MOVAVE value (741,731.5) is the mean of DOLLARS values one and two: 
\((801,123 + 682,340) / 2\).

The third MOVAVE value (749,513.7) is the mean of DOLLARS values one through three: 
\((801,123 + 682,340 + 765,078) / 3\).

The fourth MOVAVE value (712,897.3) is the mean of DOLLARS values two through four: 
\((682,340 + 765,078 + 691,274) / 3\).

For predicted values beyond the supplied values, the calculated MOVAVE values are used as 
new data points to continue the moving average. The predicted MOVAVE values (starting with 
694,975.6 for PERIOD 13) are calculated using the previous MOVAVE values as new data 
points. For example, the first predicted value (694,975.6) is the average of the data points 
from periods 11 and 12 (620,264 and 762,328) and the moving average for period 12 
(702,334.7). The calculation is: 
\[694,975 = \frac{620,264 + 762,328 + 702,334.7}{3}\].

**Example:**  
**Displaying Original Field Values in a Simple Moving Average Column**

This request defines an integer value named PERIOD to use as the independent variable for 
the moving average. It predicts three periods of values beyond the range of the retrieved data. 
It uses the keyword INPUT_FIELD as the first argument in the FORECAST parameter list. The 
trend values do not display in the report. The actual data values for DOLLARS are followed by 
the predicted values in the report column.

```

FORECAST_EXPAVE: Using Single Exponential Smoothing

The single exponential smoothing method calculates an average that allows you to choose weights to apply to newer and older values.

The following formula determines the weight given to the newest value.

\[ k = \frac{2}{1+n} \]

where:

\[ k \]

Is the newest value.

\[ n \]

Is an integer greater than one. Increasing \( n \) increases the weight assigned to the earlier observations (or data instances), as compared to the later ones.

The next calculation of the exponential moving average (EMA) value is derived by the following formula:

\[ EMA = (EMA \times (1-k)) + (\text{datavalue} \times k) \]

This means that the newest value from the data source is multiplied by the factor \( k \) and the current moving average is multiplied by the factor \((1-k)\). These quantities are then summed to generate the new EMA.

Note: When the data values are exhausted, the last data value in the sort group is used as the next data value.

Syntax: How to Calculate a Single Exponential Smoothing Column

\[
\text{FORECAST_EXPAVE}(\text{display}, \text{infield}, \text{interval}, \text{npredict}, \text{npoint1})
\]

where:

\text{display}

Keyword

Specifies which values to display for rows of output that represent existing data. Valid values are:

- **INPUT_FIELD**. This displays the original field values for rows that represent existing data.

- **MODEL_DATA**. This displays the calculated values for rows that represent existing data.
FORECAST_EXPAVE: Using Single Exponential Smoothing

**Note:** You can show both types of output for any field by creating two independent COMPUTE commands in the same request, each with a different display option.

**infield**
Is any numeric field. It can be the same field as the result field, or a different field. It cannot be a date-time field or a numeric field with date display options.

**interval**
Is the increment to add to each sort field value (after the last data point) to create the next value. This must be a positive integer. To sort in descending order, use the BY HIGHEST phrase. The result of adding this number to the sort field values is converted to the same format as the sort field.

For date fields, the minimal component in the format determines how the number is interpreted. For example, if the format is YMD, MDY, or DMY, an interval value of 2 is interpreted as meaning two days. If the format is YM, the 2 is interpreted as meaning two months.

**npredict**
Is the number of predictions for FORECAST to calculate. It must be an integer greater than or equal to zero. Zero indicates that you do not want predictions, and is only supported with a non-recursive FORECAST.

**npoint1**
For EXPAVE, this number is used to calculate the weights for each component in the average. This value must be a positive whole number. The weight, k, is calculated by the following formula:

\[ k = \frac{2}{1 + \text{npoint1}} \]

**Example:** Calculating a Single Exponential Smoothing Column

The following defines an integer value named PERIOD to use as the independent variable for the moving average. It predicts three periods of values beyond the range of retrieved data.

</tbody>
</table>

In the report, three predicted values of EXPAVE are calculated within each value of CATEGORY. For values outside the range of the data, new PERIOD values are generated by adding the interval value (1) to the prior PERIOD value.

Each average (EXPAVE value) is computed using DOLLARS values where they exist. The calculation of the moving average begins in the following way:

- The first EXPAVE value (801,123.0) is the same as the first DOLLARS value.

- The second EXPAVE value (741,731.5) is calculated as follows. Note that because of rounding and the number of decimal places used, the value derived in this sample calculation varies slightly from the one displayed in the report output:

\[ n=3 \text{ (number used to calculate weights)} \]

\[ k = \frac{2}{1+n} = \frac{2}{4} = 0.5 \]

\[ \text{EXPAVE} = (\text{EXPAVE} \times (1-k)) + (\text{new-}\text{DOLLARS} \times k) = (801123 \times 0.5) + (682340 \times 0.50) = 400561.5 + 341170 = 741731.5 \]
The third EXPAVE value (753,404.8) is calculated as follows:

\[
\text{EXPAVE} = (\text{EXPAVE} \times (1-k)) + (\text{new-DOLLARS} \times k) = (741731.5 \times 0.5) + (765078 \times 0.50) = 370865.75 + 382539 = 753404.75
\]

FORECAST_DOUBLEXP: Using Double Exponential Smoothing

Double exponential smoothing produces an exponential moving average that takes into account the tendency of data to either increase or decrease over time without repeating. This is accomplished by using two equations with two constants.

The first equation accounts for the current time period and is a weighted average of the current data value and the prior average, with an added component \(b\) that represents the trend for the previous period. The weight constant is \(k\):

\[
\text{DOUBLEXP}(t) = k \times \text{datavalue}(t) + (1-k) \times ((\text{DOUBLEXP}(t-1) + b(t-1))
\]

The second equation is the calculated trend value, and is a weighted average of the difference between the current and previous average and the trend for the previous time period. \(b(t)\) represents the average trend. The weight constant is \(g\):

\[
b(t) = g \times (\text{DOUBLEXP}(t)-\text{DOUBLEXP}(t-1)) + (1-g) \times (b(t-1))
\]

These two equations are solved to derive the smoothed average. The first smoothed average is set to the first data value. The first trend component is set to zero. For choosing the two constants, the best results are usually obtained by minimizing the mean-squared error (MSE) between the data values and the calculated averages. You may need to use nonlinear optimization techniques to find the optimal constants.

The equation used for forecasting beyond the data points with double exponential smoothing is

\[
\text{forecast}(t+m) = \text{DOUBLEXP}(t) + m \times b(t)
\]

where:

\(m\)

Is the number of time periods ahead for the forecast.

Syntax: How to Calculate a Double Exponential Smoothing Column

\[
\text{FORECAST_DOUBLEXP(display, infield, interval, npredict, npoint1, npoint2)}
\]
where:

**display**

Keyword

Specifies which values to display for rows of output that represent existing data. Valid values are:

- **INPUT_FIELD.** This displays the original field values for rows that represent existing data.
- **MODEL_DATA.** This displays the calculated values for rows that represent existing data.

**Note:** You can show both types of output for any field by creating two independent COMPUTE commands in the same request, each with a different display option.

**infield**

Is any numeric field. It can be the same field as the result field, or a different field. It cannot be a date-time field or a numeric field with date display options.

**interval**

Is the increment to add to each sort field value (after the last data point) to create the next value. This must be a positive integer. To sort in descending order, use the BY HIGHEST phrase. The result of adding this number to the sort field values is converted to the same format as the sort field.

For date fields, the minimal component in the format determines how the number is interpreted. For example, if the format is YMD, MDY, or DMY, an interval value of 2 is interpreted as meaning two days. If the format is YM, the 2 is interpreted as meaning two months.

**npredict**

Is the number of predictions for FORECAST to calculate. It must be an integer greater than or equal to zero. Zero indicates that you do not want predictions, and is only supported with a non-recursive FORECAST.

**npoint1**

For DOUBLEXP, this number is used to calculate the weights for each component in the average. This value must be a positive whole number. The weight, k, is calculated by the following formula:

\[ k = \frac{2}{1 + npoint1} \]

**npoint2**

For DOUBLEXP, this positive whole number is used to calculate the weights for each term in the trend. The weight, g, is calculated by the following formula:
\[ g = \frac{2}{1 + \text{npoint2}} \]

**Example:**  Calculating a Double Exponential Smoothing Column

The following sums the TRANSTOT field of the VIDEOTRK data source by TRANSDATE, and calculates a single exponential and double exponential moving average. The report columns show the calculated values for existing data points.

```
TABLE FILE VIDEOTRK
SUM TRANSTOT
COMPUTE EXP/D15.1 = FORECAST_EXPAVE(MODEL_DATA, TRANSTOT, 1, 0, 3);
DOUBLEXP/D15.1 = FORECAST_DOUBLEXP(MODEL_DATA, TRANSTOT, 1, 0, 3, 3);
BY TRANSDATE
WHERE TRANSDATE NE '19910617'
ON TABLE SET STYLE *

**FORECAST_SEASONAL:** Using Triple Exponential Smoothing

Triple exponential smoothing produces an exponential moving average that takes into account the tendency of data to repeat itself in intervals over time. For example, sales data that is growing and in which 25% of sales always occur during December contains both trend and seasonality. Triple exponential smoothing takes both the trend and seasonality into account by using three equations with three constants.
For triple exponential smoothing you, need to know the number of data points in each time period (designated as L in the following equations). To account for the seasonality, a seasonal index is calculated. The data is divided by the prior season index and then used in calculating the smoothed average.

The first equation accounts for the current time period, and is a weighted average of the current data value divided by the seasonal factor and the prior average adjusted for the trend for the previous period. The weight constant is k:

\[ \text{SEASONAL}(t) = k \times (\text{data value}(t)/I(t-L)) + (1-k) \times (\text{SEASONAL}(t-1) + b(t-1)) \]

The second equation is the calculated trend value, and is a weighted average of the difference between the current and previous average and the trend for the previous time period. b(t) represents the average trend. The weight constant is g:

\[ b(t) = g \times (\text{SEASONAL}(t) - \text{SEASONAL}(t-1)) + (1-g) \times (b(t-1)) \]

The third equation is the calculated seasonal index, and is a weighted average of the current data value divided by the current average and the seasonal index for the previous season. I(t) represents the average seasonal coefficient. The weight constant is p:

\[ I(t) = p \times (\text{data value}(t)/\text{SEASONAL}(t)) + (1-p) \times I(t-L) \]

These equations are solved to derive the triple smoothed average. The first smoothed average is set to the first data value. Initial values for the seasonality factors are calculated based on the maximum number of full periods of data in the data source, while the initial trend is calculated based on two periods of data. These values are calculated with the following steps:

1. The initial trend factor is calculated by the following formula:

\[ b(0) = (1/L) \times ((y(L+1)-y(1))/L + ((y(L+2)-y(2))/L + ... + (y(2L) - y(L))/L) \]

2. The calculation of the initial seasonality factor is based on the average of the data values within each period, A(j) (1<=j<=N):

\[ A(j) = (y((j-1)L+1) + y((j-1)L+2) + ... + y(jL)) / L \]

3. Then, the initial periodicity factor is given by the following formula, where N is the number of full periods available in the data, L is the number of points per period and n is a point within the period (1<= n <= L):

\[ I(n) = (y(n)/A(1) + y(L+n)/A(2) + ... + y(\lfloor N-1 \rfloor L+n)/A(N)) / N \]
The three constants must be chosen carefully. The best results are usually obtained by choosing the constants to minimize the mean-squared error (MSE) between the data values and the calculated averages. Varying the values of npoint1 and npoint2 affect the results, and some values may produce a better approximation. To search for a better approximation, you may want to find values that minimize the MSE.

The equation used to forecast beyond the last data point with triple exponential smoothing is:

\[
\text{forecast}(t+m) = (\text{SEASONAL}(t) + m \times b(t)) / I(t-L+\text{MOD}(m/L))
\]

where:

\( m \)

Is the number of periods ahead for the forecast.

**Syntax:**

How to Calculate a Triple Exponential Smoothing Column

\[
\text{FORECAST_SEASONAL}(\text{display}, \text{infield}, \text{interval}, \text{npredict}, \text{nperiod}, \text{npoint1}, \text{npoint2}, \text{npoint3})
\]

where:

\( \text{display} \)

Keyword

Specifies which values to display for rows of output that represent existing data. Valid values are:

- **INPUT_FIELD.** This displays the original field values for rows that represent existing data.

- **MODEL_DATA.** This displays the calculated values for rows that represent existing data.

**Note:** You can show both types of output for any field by creating two independent COMPUTE commands in the same request, each with a different display option.

\( \text{infield} \)

Is any numeric field. It can be the same field as the result field, or a different field. It cannot be a date-time field or a numeric field with date display options.

\( \text{interval} \)

Is the increment to add to each sort field value (after the last data point) to create the next value. This must be a positive integer. To sort in descending order, use the BY HIGHEST phrase. The result of adding this number to the sort field values is converted to the same format as the sort field.
For date fields, the minimal component in the format determines how the number is interpreted. For example, if the format is YMD, MDY, or DMY, an interval value of 2 is interpreted as meaning two days. If the format is YM, the 2 is interpreted as meaning two months.

**npredict**

Is the number of predictions for FORECAST to calculate. It must be an integer greater than or equal to zero. Zero indicates that you do not want predictions, and is only supported with a non-recursive FORECAST. For the SEASONAL method, npredict is the number of periods to calculate. The number of points generated is:

\[ n_{\text{period}} \times \text{npredict} \]

**nperiod**

For the SEASONAL method, is a positive whole number that specifies the number of data points in a period.

**npoint1**

For SEASONAL, this number is used to calculate the weights for each component in the average. This value must be a positive whole number. The weight, k, is calculated by the following formula:

\[ k = \frac{2}{1 + \text{npoint1}} \]

**npoint2**

For SEASONAL, this positive whole number is used to calculate the weights for each term in the trend. The weight, g, is calculated by the following formula:

\[ g = \frac{2}{1 + \text{npoint2}} \]

**npoint3**

For SEASONAL, this positive whole number is used to calculate the weights for each term in the seasonal adjustment. The weight, p, is calculated by the following formula:

\[ p = \frac{2}{1 + \text{npoint3}} \]
Example: Calculating a Triple Exponential Smoothing Column

In the following, the data has seasonality but no trend. Therefore, npoint2 is set high (1000) to make the trend factor negligible in the calculation:

```plaintext
TABLE FILE VIDEOTRK
SUM TRANSTOT
COMPUTE SEASONAL/D10.1 = FORECAST_SEASONAL(MODEL_DATA,TRANSTOT, 1,3,3,3,1000,1);
BY TRANSDATE
WHERE TRANSDATE NE '19910617'
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```

In the output, npredict is 3. Therefore, three periods (nine points, nperiod * npredict) are generated.

**FORECAST_LINEAR: Using a Linear Regression Equation**

The linear regression equation estimates values by assuming that the dependent variable (the new calculated values) and the independent variable (the sort field values) are related by a function that represents a straight line:

\[ y = mx + b \]

where:

- \( y \) is the dependent variable.
- \( x \) is the independent variable.
- \( m \) is the slope of the line.
- \( b \) is the y-intercept.

**FORECAST_LINEAR** uses a technique called Ordinary Least Squares to calculate values for \( m \) and \( b \) that minimize the sum of the squared differences between the data and the resulting line.

The following formulas show how \( m \) and \( b \) are calculated.

\[
m = \frac{(\sum xy - (\sum x \cdot \sum y)/n)}{(\sum x^2 - (\sum x)^2/n)}
\]

\[
b = (\sum y)/n - (m \cdot (\sum x)/n)
\]

where:

- \( n \) is the number of data points.
- \( y \) is the data values (dependent variables).
- \( x \) is the sort field values (independent variables).

Trend values, as well as predicted values, are calculated using the regression line equation.
**Syntax:** How to Calculate a Linear Regression Column

FORECAST_LINEAR(display, infield, interval, npredict)

where:

**display**
Keyword

Specifies which values to display for rows of output that represent existing data. Valid values are:

- **INPUT_FIELD.** This displays the original field values for rows that represent existing data.
- **MODEL_DATA.** This displays the calculated values for rows that represent existing data.

**Note:** You can show both types of output for any field by creating two independent COMPUTE commands in the same request, each with a different display option.

**infield**
Is any numeric field. It can be the same field as the result field, or a different field. It cannot be a date-time field or a numeric field with date display options.

**interval**
Is the increment to add to each sort field value (after the last data point) to create the next value. This must be a positive integer. To sort in descending order, use the BY HIGHEST phrase. The result of adding this number to the sort field values is converted to the same format as the sort field.

For date fields, the minimal component in the format determines how the number is interpreted. For example, if the format is YMD, MDY, or DMY, an interval value of 2 is interpreted as meaning two days. If the format is YM, the 2 is interpreted as meaning two months.

**npredict**
Is the number of predictions for FORECAST to calculate. It must be an integer greater than or equal to zero. Zero indicates that you do not want predictions, and is only supported with a non-recursive FORECAST.
**Example:** Calculating a New Linear Regression Field

The following request calculates a regression line using the VIDEOTRK data source of QUANTITY by TRANSDATE. The interval is one day, and three predicted values are calculated.

```sql
TABLE FILE VIDEOTRK
SUM QUANTITY
COMPUTE FORTOT=FORECAST_LINEAR(MODEL_DATA,QUANTITY,1,3);
BY TRANSDATE
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```

The output is shown in the following image:

<table>
<thead>
<tr>
<th>TRANSDATE</th>
<th>QUANTITY</th>
<th>FORTOT</th>
</tr>
</thead>
<tbody>
<tr>
<td>06/17/91</td>
<td>12</td>
<td>6.63</td>
</tr>
<tr>
<td>06/18/91</td>
<td>2</td>
<td>6.57</td>
</tr>
<tr>
<td>06/19/91</td>
<td>5</td>
<td>6.51</td>
</tr>
<tr>
<td>06/20/91</td>
<td>3</td>
<td>6.45</td>
</tr>
<tr>
<td>06/21/91</td>
<td>7</td>
<td>6.39</td>
</tr>
<tr>
<td>06/24/91</td>
<td>12</td>
<td>6.21</td>
</tr>
<tr>
<td>06/25/91</td>
<td>8</td>
<td>6.15</td>
</tr>
<tr>
<td>06/26/91</td>
<td>2</td>
<td>6.09</td>
</tr>
<tr>
<td>06/27/91</td>
<td>9</td>
<td>6.03</td>
</tr>
<tr>
<td>06/28/91</td>
<td>3</td>
<td>5.97</td>
</tr>
<tr>
<td>06/29/91</td>
<td></td>
<td>5.91</td>
</tr>
<tr>
<td>06/30/91</td>
<td></td>
<td>5.85</td>
</tr>
<tr>
<td>07/01/91</td>
<td></td>
<td>5.79</td>
</tr>
</tbody>
</table>

**Note:**

- Three predicted values of FORTOT are calculated. For values outside the range of the data, new TRANSDATE values are generated by adding the interval value (1) to the prior TRANSDATE value.
- There are no QUANTITY values for the generated FORTOT values.
- Each FORTOT value is computed using a regression line, calculated using all of the actual data values for QUANTITY.
TRANSDATE is the independent variable (x) and QUANTITY is the dependent variable (y). The equation is used to calculate QUANTITY FORECAST trend and predicted values.

The following version of the request charts the data values and the regression line.

```
GRAPH FILE VIDEOTRK
SUM QUANTITY
COMPUTE FORTOT=FORECAST_LINEAR(MODEL_DATA, QUANTITY, 1, 3);
BY TRANSDATE
ON GRAPH HOLD FORMAT JSCHART
ON GRAPH SET LOOKGRAPH VLINE
END
```

The output is shown in the following image.

![Graph of TRANSDATE and QUANTITY FORECAST](image)

PARTITION_AGGR: Creating Rolling Calculations

Using the PARTITION_AGGR function, you can generate rolling calculations based on a block of rows from the internal matrix of a TABLE request. In order to determine the limits of the rolling calculations, you specify a partition of the data based on either a sort field or the entire TABLE. Within either type of break, you can start calculating from the beginning of the break or a number of rows prior to or subsequent to the current row. You can stop the rolling calculation at the current row, a row past the start point, or the end of the partition.
By default, the field values used in the calculations are the summed values of a measure in the request. Certain prefix operators can be used to add a column to the internal matrix and use that column in the rolling calculations. The rolling calculation can be SUM, AVE, CNT, MIN, MAX, FST, or LST.

**Syntax:**

How to Generate Rolling Calculations Using PARTITION_AGGR

```
PARTITION_AGGR([prefix.]measure, reset_key, lower, upper, operation)
```

where:

- **prefix.** Defines an aggregation operator to apply to the measure before using it in the rolling calculation. Valid operators are:
  - **SUM.** which calculates the sum of the measure field values. SUM is the default operator.
  - **CNT.** which calculates a count of the measure field values.
  - **AVE.** which calculates the average of the measure field values.
  - **MIN.** which calculates the minimum of the measure field values.
  - **MAX.** which calculates the maximum of the measure field values.
  - **FST.** which retrieves the first value of the measure field.
  - **LST.** which retrieves the last value of the measure field.
  - **STDP.** which calculates the population standard deviation.
  - **STDS.** which calculates the sample standard deviation.

**Note:** The operators PCT., RPCT., TOT., MDN., and DST. are not supported. COMPUTEs that reference those unsupported operators are also not supported.

- **measure**
  
  Is the measure field to be aggregated. It can be a real field in the request or a calculated value generated with the COMPUTE command, as long as the COMPUTE does not reference an unsupported prefix operator.

- **reset_key**
  
  Identifies the point at which the calculation restarts. Valid values are:
  - The name of a sort field in the request.
PARTITION_AGGR: Creating Rolling Calculations

- PRESET, which uses the value of the PARTITION_ON parameter, as described in *How to Specify the Partition Size for Simplified Statistical Functions* on page 313.

- TABLE, which indicates that there is no break on a sort field.

The sort field may use BY HIGHEST to indicate a HIGH-TO-LOW sort. ACROSS COLUMNS AND is supported. BY ROWS OVER and FOR are not supported.

**lower**

Identifies the starting point for the rolling calculation. Valid values are:

- **n, -n**, which starts the calculation *n* rows forward or back from the current row.

- **B**, which starts the calculation at the beginning of the current sort break (the first line with the same sort field value as the current line).

**upper**

Identifies the ending point of the rolling calculation. The *lower* row value must precede *upper* row value.

Valid values are:

- **C**, which ends the rolling calculation at the current row in the internal matrix.

- **n, -n**, which ends the calculation *n* rows forward or back from the current row.

- **E**, which ends the rolling calculation at the end of the sort break (the last line with the same sort value as the current row.)

**Note:** The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

**operation**

Specifies the rolling calculation used on the values in the internal matrix. Supported operations are:

- **SUM**, which calculates a rolling sum.

- **AVE**, which calculates a rolling average.

- **CNT**, which counts the rows in the partition.

- **MEDIAN**.

- **MIN**, which returns the minimum value in the partition.

- **MAX**, which returns the maximum value in the partition.
MEDIAN, which returns the median value in the partition.

MODE, which returns the mode value in the partition.

FST, which returns the first value in the partition.

LST, which returns the last value in the partition.

STDP, which returns the population standard deviation in the partition. Requires using the verb PRINT to avoid duplicate aggregation.

STDS, which returns the sample standard deviation in the partition. Requires using the verb PRINT to avoid duplicate aggregation.

The calculation is performed prior to any WHERE TOTAL tests, but after any WHERE_GROUPED tests.

**Example: Calculating a Rolling Average**

The following request calculates a rolling average of the current line and the previous line in the internal matrix, within the quarter.

```sql
TABLE FILE WF_RETAIL_LITE
SUM COGS_US
COMPUTE AVE1/D12.2M = PARTITION_AGGR(COGS_US, TIME_QTR, -1, C, AVE);
BY BUSINESS_REGION
BY TIME_QTR
BY TIME_MTH
WHERE BUSINESS_REGION EQ 'North America' OR 'South America'
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. Within each quarter, the first average is just the value from Q1, as going back 1 would cross a boundary. The second average is calculated using the first two rows within that quarter, and the third average is calculated using rows 2 and 3 within the quarter.

</tr>
</tbody>
</table>

**Reference:** Usage Notes for PARTITION_AGGR

- Fields referenced in the PARTITION_AGGR parameters but not previously mentioned in the request will not be counted in column notation or propagated to HOLD files.

- Using the WITHIN phrase for a sum is the same as computing PARTITION_AGGR on the WITHIN sort field from B (beginning of sort break) to E (end of sort break) using SUM, as in the following example.
TABLE FILE WF_RETAIL_LITE
SUM COGS_US WITHIN TIME_QTR AS 'WITHIN Qtr'
COMPUTE PART_WITHIN_QTR/12.2M = PARTITION_AGGR(COGS_US, TIME_QTR, B, E, SUM);
BY BUSINESS_REGION AS Region
BY TIME_QTR
BY TIME_MTH
WHERE BUSINESS_REGION EQ 'North America' OR 'South America'
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF, $
ENDSTYLE
END

The output is shown in the following image.

<table>
<thead>
<tr>
<th>Region</th>

</tbody>
</table>
With other types of calculations, the results are not the same. For example, the following request calculates the average within quarter using the WITHIN phrase and the average within quarter using PARTITION_AGGREG.

```
TABLE FILE WF_RETAIL_LITE
SUM COGS_US AS Cost
CNT.COGS_US AS Count AVE.COGS_US WITHIN TIME_QTR AS 'Ave Within'
COMPUTE PART_WITHIN_QTR/D12.2M = PARTITION_AGGREG(COGS_US, TIME_QTR, B, E, AVE);
BY BUSINESS_REGION AS Region
BY TIME_QTR
ON TIME_QTR SUBTOTAL COGS_US CNT.COGS_US
BY TIME_MTH
WHERE BUSINESS_REGION EQ 'North America'
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
If you use PARTITION_AGGR to perform operations for specific time periods using an offset, for example, an operation on the quarters for different years, you must make sure that every quarter is represented. If some quarters are missing for some years, the offset will not access the correct data. In this case, generate a HOLD file that has every quarter represented for every year (you can use BY QUARTER ROWS OVER 1 OVER 2 OVER 3 OVER 4) and use PARTITION_AGGR on the HOLD file.
PARTITION_REF: Using Prior or Subsequent Field Values in Calculations

Use of LAST in a calculation retrieves the LAST value of the specified field the last time this calculation was performed. In contrast, the PARTITION_REF function enables you to specify both how many rows back or forward to go in the output in order to retrieve a value, and a sort break within which the retrieval will be contained.

Syntax: How to Retrieve Prior or Subsequent Field Values for Use in a Calculation

PARTITION_REF([prefix.]field, reset_key, offset)

where:

prefix
Is optional. If used, it can be one of the following aggregation operators:

- AVE. Average
- MAX. Maximum
- MIN. Minimum
- CNT. Count
- SUM. Sum

field
Is the field whose value is to be retrieved.

reset_key
Identifies the point at which the retrieval break restarts. Valid values are:

- The name of a sort field in the request.
- PRESET, which uses the value of the PARTITION_ON parameter, as described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
- TABLE, which indicates that there is no break on a sort field.

The sort field may use BY HIGHEST to indicate a HIGH-TO-LOW sort. ACROSS COLUMNS AND is supported. BY ROWS OVER and FOR are not supported.

Note: The values used in the retrieval depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.
offset

Is the integer number of records to go forward (for a positive offset) or backward (for a negative offset) to retrieve the value.

If the offset is prior to the partition boundary sort value, the return will be the default value for the field. The calculation is performed prior to any WHERE TOTAL tests, but after WHERE_GROUPED tests.

Example: Retrieving a Previous Record With PARTITION_REF

The following request retrieves the previous record within the sort field PRODUCT_CATEGORY.

```sql
TABLE FILE WF_RETAIL_LITE
SUM DAYSDELAYED
COMPUTE NEWDAYS/I5=PARTITION_REF(DAYSDELAYED, PRODUCT_CATEGORY, -1);
BY PRODUCT_CATEGORY
BY PRODUCT_SUBCATEG
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
GRID=OFF,
ENDSTYLE
END
```
PARTITION_REF: Using Prior or Subsequent Field Values in Calculations

The output is shown in the following image. The first value within each sort break is zero because there is no prior record to retrieve.

<table>
<thead>

**Reference:** Usage Notes for PARTITION_REF

- Fields referenced in the PARTITION_REF parameters but not previously mentioned in the request, will **not** be counted in column notation or propagated to HOLD files.

**INCREASE: Calculating the Difference Between the Current and a Prior Value of a Field**

Given an aggregated input field and a negative offset, INCREASE calculates the difference between the value in the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the value of the PARTITION_ON parameter described in *How to Specify the Partition Size for Simplified Statistical Functions* on page 313.
Note: The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

Syntax: How to Calculate the Difference Between the Current and a Prior Value of a Field

INCREASE([prefix.]field, offset)

where:

prefix

Is one of the following optional aggregation operators to apply to the field before using it in the calculation:

- SUM. which calculates the sum of the field values. SUM is the default value.
- CNT. which calculates a count of the field values.
- AVE. which calculates the average of the field values.
- MIN. which calculates the minimum of the field values.
- MAX. which calculates the maximum of the field values.
- FST. which retrieves the first value of the field.
- LST. which retrieves the last value of the field.

field

Numeric

Is the field to be used in the calculation.

offset

Numeric

Is a negative number indicating the number of rows back from the current row to use for the calculation.
Example: Calculating the Increase Between the Current and a Prior Value of a Field

The following request uses the default value of SET PARTITION_ON (PENULTIMATE) to calculate the increase within the PRODUCT_CATEGORY sort field between the current row and the previous row.

```
SET PARTITION_ON=PENULTIMATE
TABLE FILE wf_retail_lite
SUM QUANTITY_SOLD
COMPUTE INC = INCREASE(QUANTITY_SOLD, -1);
BY PRODUCT_CATEGORY
BY PRODUCT_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. The first value for INC is the value in the Accessories category for Quantity Sold, as there is no prior value. The second value for INC is the difference between the values for Headphones and Charger, the third is the difference between Universal Remote Controls and Headphones. Then, the calculations start over for Camcorder, which is the reset point.

</table>
PCT_INCREASE: Calculating the Percentage Difference Between the Current and a Prior Value of a Field

Given an aggregated input field and a negative offset, PCT_INCREASE calculates the percentage difference between the value in the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.

The percentage increase is calculated using the following formula:

\[
\frac{\text{current\_value} - \text{prior\_value}}{\text{prior\_value}}
\]

**Note:** The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

**Syntax:**

How to Calculate the Percentage Difference Between the Current and a Prior Value of a Field

\[
PCT\_INCREASE([\text{prefix.}]\text{field}, \text{offset})
\]

where:

- **prefix**
  - Is one of the following optional aggregation operators to apply to the field before using it in the calculation:
    - **SUM.** which calculates the sum of the field values. SUM is the default value.
    - **CNT.** which calculates a count of the field values.
    - **AVE.** which calculates the average of the field values.
    - **MIN.** which calculates the minimum of the field values.
    - **MAX.** which calculates the maximum of the field values.
    - **FST.** which retrieves the first value of the field.
    - **LST.** which retrieves the last value of the field.

- **field**
  - Numeric
  - The field to be used in the calculation.
offset
   Numeric
   Is a negative number indicating the number of rows back from the current row to use for
   the calculation.

Example:  PCT_INCREASE: Calculating the Percent Increase Between the Current and a Prior
          Value of a Field

The following request uses the default value of SET PARTITION_ON (PENULTIMATE) to calculate
the percent increase within the PRODUCTCATEGORY sort field between the current row and
the previous row.

SET PARTITION_ON=PENULTIMATE
TABLE FILE wf_retail_lite

PREVIOUS: Retrieving a Prior Value of a Field

Given an aggregated input field and a negative offset, PREVIOUS retrieves the value in a prior row, within a sort break or the entire table. The reset point for the calculation is determined by the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.

**Note:** The values used in the retrieval depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

**Syntax:** How to Retrieve a Prior Value of a Field

```plaintext
PREVIOUS([prefix.]field, offset)
```

where:

- **prefix**
  - Is one of the following optional aggregation operators to apply to the field before using it in the calculation:
    - **SUM.** which calculates the sum of the field values. SUM is the default value.
    - **CNT.** which calculates a count of the field values.
    - **AVE.** which calculates the average of the field values.
    - **MIN.** which calculates the minimum of the field values.
    - **MAX.** which calculates the maximum of the field values.
    - **FST.** which retrieves the first value of the field.
    - **LST.** which retrieves the last value of the field.

- **field**
  - Numeric or an alphanumeric field that contains all numeric digits.
  - The field to be used in the calculation.

- **offset**
  - Numeric
  - Is a negative number indicating the number of rows back from the current row to use for the retrieval.
**Example:** retrieving a prior value of a field

The following request sets the PARTITION_ON parameter to TABLE and retrieves the value of the QUANTITY_SOLD field two rows back from the current row.

```
SET PARTITION_ON=TABLE
TABLE FILE wf_retail_lite
SUM QUANTITY_SOLD
COMPUTE PREV = PREVIOUS(QUANTITY_SOLD, -2);
BY PRODUCT_CATEGORY
BY PRODUCT_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. The value of PREV in the first two rows is zero, as there are no prior rows for retrieval. From then on, each value of PREV is from the QUANTITY_SOLD value from two rows prior, with no reset points.

RUNNING_AVE: Calculating an Average Over a Group of Rows

Given an aggregated input field and a negative offset, RUNNING_AVE calculates the average of the values between the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the sort field specified, the entire table, or the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
Synopsis: How to Calculate Running Average Between the Current and a Prior Value of a Field

RUNNING_AVE(field, reset_key, lower)

where:

- **field**
  - Numeric
  - The field to be used in the calculation.

- **reset_key**
  - Identifies the point at which the running average restarts. Valid values are:
    - The name of a sort field in the request.
    - PRESET, which uses the value of the PARTITION_ON parameter, as described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
    - TABLE, which indicates that there is no break on a sort field.
  - **Note:** The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

- **lower**
  - Is the starting point in the partition for the running average. Valid values are:
    - A negative number, which identifies the offset from the current row.
    - B, which specifies the beginning of the sort group.

Example: Calculating a Running Average

The following request calculates a running average of QUANTITY_SOLD within the PRODUCT_CATEGORY sort field, always starting from the beginning of the sort break.

```sql
TABLE FILE wf_retail_lite
SUM QUANTITY_SOLD
COMPUTE RAVE = RUNNING_AVE(QUANTITY_SOLD,PRODUCT_CATEGORY,B);
BY PRODUCT_CATEGORY
BY PRODUCT_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. The first value for RAVE is the value in the Accessories category for Quantity Sold, as there is no prior value. The second value for RAVE is the average of the values for Headphones and Charger, the third is the average of the values for Headphones, Charger, and Universal Remote Controls. Then, the calculations start over for Camcorder, which is the reset point.

RUNNING_MAX: Calculating a Maximum Over a Group of Rows

RUNNING_MAX: Calculating a Maximum Over a Group of Rows

Given an aggregated input field and an offset, RUNNING_MAX calculates the maximum of the values between the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the sort field specified, the entire table, or the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.

Syntax:

How to Calculate Running Maximum Between the Current and a Prior Value of a Field

RUNNING_MAX(field, reset_key, lower)

where:

field
Numeric or an alphanumeric field that contains all numeric digits.

The field to be used in the calculation.

reset_key
Identifies the point at which the running maximum restarts. Valid values are:

- The name of a sort field in the request.
- PRESET, which uses the value of the PARTITION_ON parameter, as described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
- TABLE, which indicates that there is no break on a sort field.

Note: The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

lower
Is the starting point in the partition for the running maximum. Valid values are:

- A negative number, which identifies the offset from the current row.
- B, which specifies the beginning of the sort group.
Example: Calculating a Running Maximum

The following request calculates a running maximum for the rows from the beginning of the table to the current value of QUANTITY_SOLD, with no reset point.

```
TABLE FILE wf_retail_lite
SUM QUANTITY_SOLD
COMPUTE RMAX = RUNNING_MAX(QUANTITY_SOLD,TABLE,B);
BY PRODUCTCATEGORY
BY PRODUCT_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. The first value for RMAX is the value in the Accessories category for Quantity Sold, as there is no prior value. The second value for RMAX is the value for Headphones, as that value is larger. The third value for RMAX is still the value for Headphones, as that value is larger than the Quantity Sold value in the third row. Since the maximum value in the table occurs for Blu Ray, that value is repeated on all future rows, as there is no reset point.

</table>
RUNNING_MIN: Calculating a Minimum Over a Group of Rows

Given an aggregated input field and an offset, RUNNING_MIN calculates the minimum of the values between the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the sort field specified, the entire table, or the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.

Syntax: How to Calculate Running Minimum Between the Current and a Prior Value of a Field

RUNNING_MIN(field, reset_key, lower)

where:

field

Numeric or an alphanumeric field that contains all numeric digits.

The field to be used in the calculation.

reset_key

Identifies the point at which the running minimum restarts. Valid values are:

- The name of a sort field in the request.
- PRESET, which uses the value of the PARTITION_ON parameter, as described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
- TABLE, which indicates that there is no break on a sort field.

Note: The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

lower

Is the starting point in the partition for the running minimum. Valid values are:

- A negative number, which identifies the offset from the current row.
- B, which specifies the beginning of the sort group.

Example: Calculating a Running Minimum

The following request calculates a running minimum of QUANTITY_SOLD within the PRODUCT_CATEGORY sort field (the sort break defined by SET PARTITION_ON = PENULTIMATE), always starting from the beginning of the sort break.
RUNNING_MIN: Calculating a Minimum Over a Group of Rows

```sql
SET PARTITION_ON=PENULTIMATE
TABLE FILE wf_retail_lite
SUM QUANTITY_SOLD
COMPUTE RMIN = \texttt{RUNNING\_MIN(QUANTITY\_SOLD,PRESET,B)};
BY PRODUCT\_CATEGORY
BY PRODUCT\_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```
The output is shown in the following image. The first value for RMIN is the value in the Accessories category for Quantity Sold, as there is no prior value. The second value for RMIN is the value from the first row again (Charger), as that is smaller than the value in the second row. The third is the same again, as it is still the smallest. Then, the calculations start over for Camcorder, which is the reset point.

RUNNING_SUM: Calculating a Sum Over a Group of Rows

Given an aggregated input field and an offset, RUNNING_SUM calculates the sum of the values between the current row of the report output and one or more prior rows, within a sort break or the entire table. The reset point for the calculation is determined by the sort field specified, the entire table, or the value of the PARTITION_ON parameter described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.

Syntax: How to Calculate Running Sum Between the Current and a Prior Value of a Field

RUNNING_SUM(field, reset_key, lower)

where:

field
Numeric
The field to be used in the calculation.

reset_key
Identifies the point at which the running sum restarts. Valid values are:

- The name of a sort field in the request.
- PRESET, which uses the value of the PARTITION_ON parameter, as described in How to Specify the Partition Size for Simplified Statistical Functions on page 313.
- TABLE, which indicates that there is no break on a sort field.

Note: The values used in the calculations depend on the sort sequence (ascending or descending) specified in the request. Be aware that displaying a date or time dimension in descending order may produce different results than those you may expect.

lower
Is the starting point in the partition for the running sum. Valid values are:

- A negative number, which identifies the offset from the current row.
- B, which specifies the beginning of the sort group.
\textbf{Example: Calculating a Running Sum}

The following request calculates a running sum of the current value and previous value of QUANTITY_SOLD within the reset point set by the PARTITION_ON parameter, which is the sort field PRODUCT_CATEGORY.

\begin{verbatim}
SET PARTITION_ON=PENULTIMATE TABLE FILE wf_retail_lite SUM QUANTITY_SOLD
COMPUTE RSUM = \texttt{RUNNING\_SUM(QUANTITY\_SOLD,PRESET,-1)};
BY PRODUCT\_CATEGORY
BY PRODUCT\_SUBCATEG
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
\end{verbatim}
The output is shown in the following image. The first value for RSUM is the value in the Accessories category for Quantity Sold, as there is no prior value. The second value for RSUM is the sum of the values for Headphones and Charger, the third is the sum of the values for Headphones and Universal Remote Controls. Then, the calculations start over for Camcorder, which is the reset point.

</tbody>
</table>
Simplified character functions have streamlined parameter lists, similar to those used by SQL functions. In some cases, these simplified functions provide slightly different functionality than previous versions of similar functions.

The simplified functions do not have an output argument. Each function returns a value that has a specific data type.

When used in a request against a relational data source, these functions are optimized (passed to the RDBMS for processing).

In this chapter:

- **CHAR_LENGTH**: Returning the Length in Characters of a String
- **CONCAT**: Concatenating Strings
- **DIGITS**: Converting a Number to a Character String
- **GET_TOKEN**: Extracting a Token Based on a String of Delimiters
- **INITCAP**: Capitalizing the First Letter of Each Word in a String
- **LAST_NONBLANK**: Retrieving the Last Field Value That is Neither Blank nor Missing
- **LOWER**: Returning a String With All Letters Lowercase
- **LPAD**: Left-Padding a Character String
- **LTRIM**: Removing Blanks From the Left End of a String
- **POSITION**: Returning the First Position of a Substring in a Source String
- **REGEX**: Matching a String to a Regular Expression
- **REPLACE**: Replacing a String
- **RPAD**: Right-Padding a Character String
- **RTRIM**: Removing Blanks From the Right End of a String
- **SPLIT**: Extracting an Element From a String
- **SUBSTRING**: Extracting a Substring From a Source String
- **TOKEN**: Extracting a Token From a String
- **TRIM_**: Removing a Leading Character, Trailing Character, or Both From a String
- **UPPER**: Returning a String With All Letters Uppercase
CHAR_LENGTH: Returning the Length in Characters of a String

The CHAR_LENGTH function returns the length, in characters, of a string. In Unicode environments, this function uses character semantics, so that the length in characters may not be the same as the length in bytes. If the string includes trailing blanks, these are counted in the returned length. Therefore, if the format source string is type An, the returned value will always be n.

Syntax: How to Return the Length of a String in Characters

CHAR_LENGTH(string)

where:

string
   Alphanumeric
   Is the string whose length is returned.

The data type of the returned length value is Integer.

Example: Returning the Length of a String

LASTNAME has format A15V and contains the last name with trailing blanks removed. CHAR_LENGTH returns the number of characters:

CHAR_LENGTH(LASTNAME)

For SMITH, the result is 5.

CONCAT: Concatenating Strings

CONCAT concatenates two strings. The output is returned as variable length alphanumeric.

Syntax: How to Concatenate Strings

CONCAT(string1, string2)
where:

string2
  Alphanumeric
  Is a string to be concatenated.

string1
  Alphanumeric
  Is a string to be concatenated.

**Example:**  Concatenating Strings

CONCAT concatenates CITY and STATE.

**CONCAT (CITY, STATE)**

For Montgomery Alabama, the result is Montgomery Alabama.

**DIGITS: Converting a Number to a Character String**

Given a number, DIGITS converts it to a character string of the specified length. The format of the field that contains the number must be Integer.

**Syntax:**  How to Convert a Number to a Character String

**DIGITS(number, length)**

where:

**number**
  Integer
  Is the number to be converted, stored in a field with data type Integer.

**length**
  Integer between 1 and 10
  Is the length of the returned character string. If length is longer than the number of digits in the number being converted, the returned value is padded on the left with zeros. If length is shorter than the number of digits in the number being converted, the returned value is truncated on the left.

**Example:**  Converting a Number to a Character String

DIGITS converts the integer expression ID_PRODUCT+1 to a six-character string:

**DIGITS(ID_PRODUCT, 6)**
For the number 1106, the result is the character string '001106'.

Reference: Usage Notes for DIGITS

- Only I format numbers will be converted. D, P, and F formats generate error messages and should be converted to I before using the DIGITS function. The limit for the number that can be converted is 2 GB.
- Negative integers are turned into positive integers.
- Integer formats with decimal places are truncated.
- DIGITS is not supported in Dialogue Manager.

GET_TOKEN: Extracting a Token Based on a String of Delimiters

GET_TOKEN extracts a token (substring) based on a string that can contain multiple characters, each of which represents a single-character delimiter.

Syntax: How to Extract a Token Based on a String of Delimiters

GET_TOKEN(string, delimiter_string, occurrence)

where:

string
Alphanumeric

Is the input string from which the token will be extracted. This can be an alphanumerical field or constant.

delimiter_string
Alphanumeric constant

Is a string that contains the list of delimiter characters. For example, ';,' contains three delimiter characters, semi-colon, blank space, and comma.

occurrence
Integer constant

Is a positive integer that specifies the token to be extracted. A negative integer will be accepted in the syntax, but will not extract a token. The value zero (0) is not supported.

Example: Extracting a Token Based on a String of Delimiters

GET_TOKEN extracts a token based on a string of delimiters.

GET_TOKEN(InputString, ';', 4)
For input string 'ABC,DEF;GHI/JKL', the result is JKL.

**INITCAP: Capitalizing the First Letter of Each Word in a String**

INITCAP capitalizes the first letter of each word in an input string and makes all other letters lowercase. A word starts at the beginning of the string, after a blank space, or after a special character.

**Syntax:**

How to Capitalize the First Letter of Each Word in a String

\[
\text{INITCAP}(\text{input\_string})
\]

where:

\[\text{input\_string}\]

Alphanumeric

Is the string to capitalize.

**Example:**

Capitalizing the First Letter of Each Word in a String

INITCAP capitalizes the first letter of each word.

\[
\text{INITCAP}(\text{NewName})
\]

For the string abc,def!ghi'jKL MNO, the result is Abc,Def!Ghi'Jkl Mno.

For MCKNIGHT, the result is Mcknight.

**LAST_NONBLANK: Retrieving the Last Field Value That is Neither Blank nor Missing**

LAST_NONBLANK retrieves the last field value that is neither blank nor missing. If all previous values are either blank or missing, LAST_NONBLANK returns a missing value.

**Syntax:**

How to Return the Last Value That is Neither Blank nor Missing

\[
\text{LAST\_NONBLANK}(\text{field})
\]

where:

\[\text{field}\]

Is the field name whose last non-blank value is to be retrieved. If the current value is not blank or missing, the current value is returned.

**Note:** LAST_NONBLANK cannot be used in a compound expression, for example, as part of an IF condition.
**Example:** Retrieving the Last Non-Blank Value

Consider the following delimited file named `input1.csv` that has two fields named `FIELD_1` and `FIELD_2`.

```
A,
B,
C,
```

The `input1` Master File follows.

```
FILENAME=INPUT1, SUFFIX=DFIX,
DATASET=baseapp/input1.csv(LRECL 15 RECFM V, BV_NAMESPACE=OFF, $
SEGMENT=INPUT1, SEGTYPE=S0, $
  FIELDNAME=FIELD_1, ALIAS=E01, USAGE=A1V, ACTUAL=A1V,
  MISSING=ON, $
  FIELDNAME=FIELD_2, ALIAS=E02, USAGE=A1V, ACTUAL=A1V,
  MISSING=ON, $
The input1 Access File follows.

SENAME=INPUT1,
  DELIMITER=',','
  HEADER=NO,
  PRESERVESPACE=NO,
  CDN=COMMAS_DOT,
  CONNECTION=<local>, $
```

The following request displays the `FIELD_1` values and computes the last non-blank value for each `FIELD_1` value.

```
TABLE FILE baseapp/INPUT1
PRINT FIELD_1 AS Input
COMPUTE
  Last_NonBlank/A1 MISSING ON = LAST_NONBLANK(FIELD_1);
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END
```

**LAST_NONBLANK: Retrieving the Last Field Value That is Neither Blank nor Missing**
The output is shown in the following image.

<table>
<thead>
<tr>
<th>Input</th>
<th>Last</th>
<th>NonBlank</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>.</td>
<td></td>
</tr>
<tr>
<td>A</td>
<td>A</td>
<td></td>
</tr>
<tr>
<td>.</td>
<td>A</td>
<td></td>
</tr>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>B</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>C</td>
<td></td>
</tr>
</tbody>
</table>

**LOWER: Returning a String With All Letters Lowercase**

The LOWER function takes a source string and returns a string of the same data type with all letters translated to lowercase.

**Syntax:**

\[
\text{LOWER} (\text{string})
\]

where:

- \( \text{string} \)
  
  Alphanumeric
  
  Is the string to convert to lowercase.

The returned string is the same data type and length as the source string.

**Example:**

**Converting a String to Lowercase**

LOWER converts LAST_NAME to lowercase.

\[
\text{LOWER}(\text{LAST\_NAME})
\]

For STEVENS, the result is stevens.

**LPAD: Left-Padding a Character String**

LPAD uses a specified character and output length to return a character string padded on the left with that character.
Syntax: How to Pad a Character String on the Left

\[
\text{LPAD}(\text{string, out_length, pad_character})
\]

where:

- **string**
  - Fixed length alphanumeric
  - Is a string to pad on the left side.

- **out_length**
  - Integer
  - Is the length of the output string after padding.

- **pad_character**
  - Fixed length alphanumeric
  - Is a single character to use for padding.

Example: Left-Padding a String

\[
\text{LPAD} \text{ left-pads the PRODUCT\_CATEGORY column with @ symbols:}
\]

\[
\text{LPAD}(\text{PRODUCT\_CATEGORY, 25, '@'})
\]

For Stereo Systems, the output is @@@@@@@@@@@@@Stereo Systems.

Reference: Usage Notes for LPAD

- To use the single quotation mark (') as the padding character, you must double it and enclose the two single quotation marks within single quotation marks (LPAD(COUNTRY, 20,'''')). You can use an amper variable in quotation marks for this parameter, but you cannot use a field, virtual or real.

- Input can be fixed or variable length alphanumeric.

- Output, when optimized to SQL, will always be data type VARCHAR.

- If the output is specified as shorter than the original input, the original data will be truncated, leaving only the padding characters. The output length can be specified as a positive integer or an unquoted &variable (indicating a numeric).

LTRIM: Removing Blanks From the Left End of a String

The LTRIM function removes all blanks from the left end of a string.
**Syntax:**  
How to Remove Blanks From the Left End of a String

\[
\text{LTRIM}(\text{string})
\]

where:

\text{string}

Alphanumeric

Is the string to trim on the left.

The data type of the returned string is AnV, with the same maximum length as the source string.

**Example:**  
Removing Blanks From the Left End of a String

RDIRECTOR has the director name right justified. LTRIM removes the leading blanks.

\[
\text{LTRIM}(\text{RDIRECTOR})
\]

For BROOKS R. the result is BROOKS R.

**PATTERNS:**  
Returning a Pattern That Represents the Structure of the Input String

PATTERNS returns a string that represents the structure of the input argument. The returned pattern includes the following characters:

- A is returned for any position in the input string that has an uppercase letter.
- a is returned for any position in the input string that has a lowercase letter.
- 9 is returned for any position in the input string that has a digit.

Note that special characters (for example, +/-=%) are returned exactly as they were in the input string.

The output is returned as variable length alphanumeric.

**Syntax:**  
How to Return a String That Represents the Pattern Profile of the Input Argument

\[
\text{PATTERNS}(\text{string})
\]

where:

\text{string}

Alphanumeric

Is a string whose pattern will be returned.
**Example:** Returning a Pattern Representing an Input String

PATTERNS returns the pattern representing the field ADDRESS_LINE_1.

```
PATTERNS(ADDRESS_LINE_1)
```

For 1010 Milam St # Ifp-2352

The result is 9999 Aaaaa Aa # Aaa-9999.

**POSITION:** Returning the First Position of a Substring in a Source String

The POSITION function returns the first position (in characters) of a substring in a source string.

**Syntax:** How to Return the First Position of a Substring in a Source String

```
POSITION(pattern, string)
```

where:

**pattern**

- Alphanumeric
  - Is the substring whose position you want to locate. The string can be as short as a single character, including a single blank.

**string**

- Alphanumeric
  - Is the string in which to find the pattern.

The data type of the returned value is Integer.

**Example:** Returning the First Position of a Substring

POSITION determines the position of the first capital letter I in LAST_NAME.

```
POSITION('I', LAST_NAME)
```

For STEVENS, the result is 0.

For SMITH, the result is 3.

**REGEX:** Matching a String to a Regular Expression

The REGEX function matches a string to a regular expression and returns true (1) if it matches and false (0) if it does not match.
A regular expression is a sequence of special characters and literal characters that you can combine to form a search pattern.

Many references for regular expressions exist on the web.

**Syntax:** How to Match a String to a Regular Expression

```plaintext
REGEX(string, regular_expression)
```

where:

- `string` Alphanumeric
  Is the character string to match.

- `regular_expression` Alphanumeric
  Is a regular expression enclosed in single quotation marks constructed using literals and metacharacters. The following metacharacters are supported:

  - . represents any single character
  - * represents zero or more occurrences
  - + represents one or more occurrences
  - ? represents zero or one occurrence
  - ^ represents beginning of line
  - $ represents end of line
  - [] represents any one character in the set listed within the brackets
  - [^] represents any one character not in the set listed within the brackets
  - | represents the Or operator
  - \ is the Escape Special Character
  - () contains a character sequence

For example, the regular expression `'^Ste(v|ph)en$'` matches values starting with Ste followed by either ph or v, and ending with en.

**Note:** The output value is numeric.
Example: Matching a String Against a Regular Expression

REGEX matches the FIRSTNAME field against the regular expression ‘^Sara(h?)$’, which matches Sara or Sarah:

\[ \text{REGEX(FIRSTNAME, '^[Sara(h?)$')} \]

For Sara, the result is 1.
For Amber, the result is 0.

REPLACE: Replacing a String

REPLACE replaces all instances of a search string in an input string with the given replacement string. The output is always variable length alphanumeric with a length determined by the input parameters.

Syntax: How to Replace all Instances of a String

\[ \text{REPLACE(input_string, search_string, replacement)} \]

where:

\[ \text{input_string} \]

Alphanumeric or text (An, AnV, TX)
Is the input string.

\[ \text{search_string} \]

Alphanumeric or text (An, AnV, TX)
Is the string to search for within the input string.

\[ \text{replacement} \]

Alphanumeric or text (An, AnV, TX)
Is the replacement string to be substituted for the search string. It can be a null string ("").

Example: Replacing a String

REPLACE replaces the string ‘South’ in the Country Name with the string ‘S.’

\[ \text{REPLACE(COUNTRY_NAME, 'SOUTH', 'S.')}; \]

For South Africa, the result is S. Africa.
Example: Replacing All Instances of a String

REPLACE removes the characters 'DAY' from the string DAY1:

\[ \text{REPLACE(DAY1, 'DAY', '')} \]

For 'SUNDAY MONDAY TUESDAY', the result is 'SUN MON TUES'.

RPAD: Right-Padding a Character String

RPAD uses a specified character and output length to return a character string padded on the right with that character.

Syntax: How to Pad a Character String on the Right

\[ \text{RPAD(string, out_length, pad_character)} \]

where:

string
Alphanumeric
Is a string to pad on the right side.

out_length
Integer
Is the length of the output string after padding.

pad_character
Alphanumeric
Is a single character to use for padding.

Example: Right-Padding a String

RPAD right-pads the PRODUCTCATEGORY column with @ symbols:

\[ \text{RPAD(PRODUCTCATEGORY, 25, '@')} \]

For Stereo Systems, the output is Stereo Systems@@@@@@@@@@@@.

Reference: Usage Notes for RPAD

- The input string can be data type AnV, VARCHAR, TX, and An.
- Output can only be AnV or An.
When working with relational VARCHAR columns, there is no need to trim trailing spaces from the field if they are not desired. However, with An and AnV fields derived from An fields, the trailing spaces are part of the data and will be included in the output, with the padding being placed to the right of these positions. You can use TRIM or TRIMV to remove these trailing spaces prior to applying the RPAD function.

RTRIM: Removing Blanks From the Right End of a String

The RTRIM function removes all blanks from the right end of a string.

**Syntax:**

RTRIM(string)

where:

string

Alphanumeric

Is the string to trim on the right.

The data type of the returned string is AnV, with the same maximum length as the source string.

**Example:**

Removing Blanks From the Right End of a String

RTRIM removes trailing blanks from DIRECTOR.

RTRIM(DIRECTOR)

For BROOKS R., the result is BROOKS R.

SPLIT: Extracting an Element From a String

The SPLIT function returns a specific type of element from a string. The output is returned as variable length alphanumeric.

**Syntax:**

SPLIT(element, string)
where:

**element**

Can be one of the following keywords:

- **EMAIL_DOMAIN.** Is the domain name portion of an email address in the string.
- **EMAIL_USERID.** Is the user ID portion of an email address in the string.
- **URL_PROTOCOL.** Is the URL protocol for a URL in the string.
- **URL_HOST.** Is the host name of the URL in the string.
- **URL_PORT.** Is the port number of the URL in the string.
- **URL_PATH.** Is the URL path for a URL in the string.
- **NAME_FIRST.** Is the first token (group of characters) in the string. Tokens are delimited by blanks.
- **NAME_LAST.** Is the last token (group of characters) in the string. Tokens are delimited by blanks.

**string**

Alphanumeric

Is the string from which the element will be extracted.

**Example:**  **Extracting an Element From a String**

SPLIT extracts the URL protocol from the string STRING1.

\[SPLIT(URL_PROTOCOL, STRING1)\]

For the URL ‘http://www.informationbuilders.com’ in STRING1, the result is http.

**SUBSTRING: Extracting a Substring From a Source String**

The SUBSTRING function extracts a substring from a source string. If the ending position you specify for the substring is past the end of the source string, the position of the last character of the source string becomes the ending position of the substring.
Syntax: **How to Extract a Substring From a Source String**

\[
\text{SUBSTRING} \left( \text{string}, \, \text{position}, \, \text{length} \right)
\]

where:

**string**
- Alphanumeric
  - Is the string from which to extract the substring. It can be a field, a literal in single quotation marks ("), or a variable.

**position**
- Positive Integer
  - Is the starting position of the substring in **string**.

**length**
- Integer
  - Is the limit for the length of the substring. The ending position of the substring is calculated as \( \text{position} + \text{length} - 1 \). If the calculated position beyond the end of the source string, the position of the last character of **string** becomes the ending position.

The data type of the returned substring is AnV.

**Example:** **Extracting a Substring From a Source String**

POSITION determines the position of the first letter I in LAST_NAME.

\[
\text{SUBSTRING} \left( \text{LAST_NAME}, \, \text{I\_IN\_NAME}, \, \text{I\_IN\_NAME+2} \right)
\]

For BANNING, the result is 5.

**TOKEN:** **Extracting a Token From a String**

The token function extracts a token (substring) from a string of characters. The tokens are separated by a delimiter consisting of one or more characters and specified by a token number reflecting the position of the token in the string.

**Syntax:** **How to Extract a Token From a String**

\[
\text{TOKEN} \left( \text{string}, \, \text{delimiter}, \, \text{number} \right)
\]
where:

**string**
Fixed length alphanumeric

Is the character string from which to extract the token.

**delimiter**
Fixed length alphanumeric

Is a delimiter consisting of one or more characters.

TOKEN can be optimized if the delimiter consists of a single character.

**number**
Integer

Is the token number to extract.

**Example:**  **Extracting a Token From a String**

TOKEN extracts the second token from the PRODUCT_SUBCATEG column, where the delimiter is a blank:

TOKEN(PRODUCT_SUBCATEG, ' ', 2)

For *iPod Docking Station*, the result is *Docking*.

**TRIM_: Removing a Leading Character, Trailing Character, or Both From a String**

The TRIM_ function removes all occurrences of a single character from either the beginning or end of a string, or both.

**Note:**

- Leading and trailing blanks count as characters. If the character you want to remove is preceded (for leading) or followed (for trailing) by a blank, the character will not be removed. Alphanumeric fields that are longer than the number of characters stored within them are padded with trailing blanks.
- The function will be optimized when run against a relational DBMS that supports trimming the character and location specified.
**Syntax:**

How to Remove a Leading Character, Trailing Character, or Both From a String

\[ \text{TRIM}_\text{where}( \text{pattern}, \text{string}) \]

where:

- \textit{where}
  - Keyword
    - Defines where to trim the source string. Valid values are:
      - \textbf{LEADING}, which removes leading occurrences.
      - \textbf{TRAILING}, which removes trailing occurrences.
      - \textbf{BOTH}, which removes leading and trailing occurrences.

- \textit{pattern}
  - Alphanumeric
    - Is a single character, enclosed in single quotation marks (""'), whose occurrences are to be removed from \textit{string}. For example, the character can be a single blank (" ").

- \textit{string}
  - Alphanumeric
    - Is the string to be trimmed.

The data type of the returned string is AnV.

**Example:**

**Trimming a Character From a String**

\[ \text{TRIM}_\text{LEADING}( 'B', \text{DIRECTOR}) \]

For BROOKS R., the result is ROOKS R.

**UPPER: Returning a String With All Letters Uppercase**

The UPPER function takes a source string and returns a string of the same data type with all letters translated to uppercase.
Syntax: How to Return a String With All Letters Uppercase

\[ \text{UPPER}(\text{string}) \]

where:

\[ \text{string} \]

Alphanumeric

Is the string to convert to uppercase.

The returned string is the same data type and length as the source string.

Example: Converting Letters to Uppercase

LAST\_NAME\_MIXED has the last name in mixed case. UPPER converts LAST\_NAME\_MIXED to uppercase.

\[ \text{UPPER}(\text{LAST\_NAME\_MIXED}) \]

For Banning, the result is BANNING.
Chapter 4

Character Functions

Character functions manipulate alphanumeric fields and character strings.

In this chapter:

- ARGLEN: Measuring the Length of a String
- ASIS: Distinguishing Between Space and Zero
- BITSON: Determining If a Bit Is On or Off
- BITVAL: Evaluating a Bit String as an Integer
- BYTVAL: Translating a Character to Decimal
- CHKFMT: Checking the Format of a String
- CHKNUM: Checking a String for Numeric Format
- CTRAN: Translating One Character to Another
- CTRFLD: Centering a Character String
- EDIT: Extracting or Adding Characters
- GETTOK: Extracting a Substring (Token)
- LCWORD: Converting a String to Mixed-Case
- LCWORD2: Converting a String to Mixed-Case
- LCWORD3: Converting a String to Mixed-Case
- OVRLAY: Overlaying a Character String
- PARAG: Dividing Text Into Smaller Lines
- PATTERN: Generating a Pattern From a String
- POSIT: Finding the Beginning of a Substring
- REVERSE: Reversing the Characters in a String
- RJUST: Right-Justifying a Character String
- SOUNDEX: Comparing Character Strings Phonetically
- SPELLNM: Spelling Out a Dollar Amount
- SQUEEZ: Reducing Multiple Spaces to a Single Space
- STRIP: Removing a Character From a String
- STRREP: Replacing Character Strings
- SUBSTR: Extracting a Substring
- TRIM: Removing Leading and Trailing Occurrences
- UPCASE: Converting Text to Uppercase
- XMLDECOD: Decoding XML-Encoded Characters
ARGLEN: Measuring the Length of a String

The ARGLEN function measures the length of a character string within a field, excluding trailing spaces. The field format in a Master File specifies the length of a field, including trailing spaces.

Syntax: How to Measure the Length of a Character String

ARGLEN(length, source_string, output)

where:

length
Integer
Is the length of the field containing the character string, or a field that contains the length.

source_string
Alphanumeric
Is the name of the field containing the character string.

output
Integer

Example: Measuring the Length of a Character String

ARGLEN determines the length of the character string in LAST_NAME and stores the result in a column with the format I3:

ARGLEN(15, LAST_NAME, 'I3')

For SMITH, the result is 5.

For BLACKWOOD, the result is 9.

ASIS: Distinguishing Between Space and Zero

The ASIS function distinguishes between a space and a zero in Dialogue Manager. It differentiates between a numeric string, a constant or variable defined as a numeric string (number within single quotation marks), and a field defined simply as numeric. ASIS forces a variable to be evaluated as it is entered rather than be converted to a number. It is used in Dialogue Manager equality expressions only.
**Syntax:** How to Distinguish Between a Space and a Zero

\[
\text{ASIS}(argument)
\]

where:

- **argument**
  - Alphanumeric
  - Is the value to be evaluated.
  - If you specify an alphanumeric literal, enclose it in single quotation marks. If you specify an expression, use parentheses, as needed, to ensure the correct order of evaluation.

**Example:** Distinguishing Between a Space and a Zero

The first request does not use ASIS. No difference is detected between variables defined as a space and 0.

```
-SET &VAR1 = ' ';  
-SET &VAR2 = 0;  
-IF &VAR2 EQ &VAR1 GOTO ONE;  
-TYPE VAR1 &VAR1 EQ VAR2 &VAR2 NOT TRUE  
-QUIT  
-ONE  
-TYPE VAR1 &VAR1 EQ VAR2 &VAR2 TRUE
```

The output is:

```
VAR1 EQ VAR2 0 TRUE
```

The next request uses ASIS to distinguish between the two variables.

```
-SET &VAR1 = ' ';  
-SET &VAR2 = 0;  
-IF &VAR2 EQ ASIS(&VAR1) GOTO ONE;  
-TYPE VAR1 &VAR1 EQ VAR2 &VAR2 NOT TRUE  
-QUIT  
-ONE  
-TYPE VAR1 &VAR1 EQ VAR2 &VAR2 TRUE
```

The output is:

```
VAR1 EQ VAR2 0 NOT TRUE
```
**Reference:** Usage Notes for ASIS

In general, Dialogue Manager variables are treated as alphanumeric values. However, a Dialogue Manager variable with the value of `'.'` may be treated as an alphanumeric value (`'.'`) or a number (0) depending on the context used.

- If the Dialogue Manager variable `'.'` is used in a mathematical expression, its value will be treated as a number. For example, in the following request, &DMVAR1 is used in an arithmetic expression and is evaluated as zero (0).

```
-SET &DMVAR1=.';
-SET &DMVAR2=10 + &DMVAR1;
-TYPE DMVAR2 = &DMVAR2
```

The output is;

```
DMVAR2 = 10
```

- If the Dialogue Manager variable value `'.'` is used in an IF test and is compared to the values `' ', '0', or '.', the result will be TRUE even if ASIS is used, as shown in the following example. The following IF tests all evaluate to TRUE.

```
-SET &DMVAR1=.';
-SET &DMVAR2=IF &DMVAR1 EQ ' ' THEN 'TRUE' ELSE 'FALSE';
-SET &DMVAR3=IF &DMVAR1 EQ '.' THEN 'TRUE' ELSE 'FALSE';
-SET &DMVAR4=IF &DMVAR1 EQ '0' THEN 'TRUE' ELSE 'FALSE';
```

- If the Dialogue Manager variable is used with ASIS, the result of the ASIS function will be always be considered alphanumeric and will distinguish between the space (`' '`), zero (`'0'`), or period (`'.'`), as in the following example. The following IF tests all evaluate to TRUE.

```
-SET &DMVAR2=IF ASIS('.') EQ ' ' THEN 'TRUE' ELSE 'FALSE';
-SET &DMVAR3=IF ASIS(' ') EQ ' ' THEN 'TRUE' ELSE 'FALSE';
-SET &DMVAR4=IF ASIS('0') EQ '0' THEN 'TRUE' ELSE 'FALSE';
```

- Comparing ASIS('0') to `' '` and ASIS(' ') to `'0'` always evaluates to FALSE.

**BITSON: Determining If a Bit Is On or Off**

The BITSON function evaluates an individual bit within a character string to determine whether it is on or off. If the bit is on, BITSON returns a value of 1. If the bit is off, it returns a value of 0. This function is useful in interpreting multi-punch data, where each punch conveys an item of information.
**Syntax:** How to Determine If a Bit Is On or Off

BITSON(bitnumber, source_string, output)

where:

*bitnumber*

  Integer

  Is the number of the bit to be evaluated, counted from the left-most bit in the character string.

*source_string*

  Alphanumeric

  Is the character string to be evaluated. The character string is in multiple eight-bit blocks.

*output*

  Integer

  Is the name of the field that contains the result, or the format of the output value enclosed in single quotation marks.

**Example:** Evaluating a Bit in a Field

BITSON evaluates the 24th bit of LAST_NAME:

\`\`BITSON(24, LAST_NAME, '11')\`

For SMITH, the result is 1.

For CROSS, the result is 9.

**BITVAL: Evaluating a Bit String as an Integer**

The BITVAL function evaluates a string of bits within a character string. The bit string can be any group of bits within the character string and can cross byte and word boundaries. The function evaluates the subset of bits in the string as an integer value.

If the number of bits is:

- Less than 1, the returned value is 0.
- Between 1 and 31 (the recommended range), the returned value is a zero or positive number representing the bits specified, extended with high-order zeroes for a total of 32 bits.
- Exactly 32, the returned value is the positive, zero, or the complement value of negative two, of the specified 32 bits.
Greater than 32 (33 or more), the returned value is the positive, zero, or the complement value of negative two, of the rightmost 32 bits specified.

**Syntax:**

**How to Evaluate a Bit String**

BITVAL(source_string, startbit, number, output)

where:

- **source_string**
  - Alphanumeric
  - Is the character string to be evaluated.

- **startbit**
  - Integer
  - Is the number of the first bit in the bit string, counting from the left-most bit in the character string. If this argument is less than or equal to 0, the function returns a value of zero.

- **number**
  - Integer
  - Is the number of bits in the subset of bits. If this argument is less than or equal to 0, the function returns a value of zero.

- **output**
  - Integer

**Example:** **Evaluating a Bit String**

BITVAL evaluates the bits 12 through 20 of LAST_NAME and stores the result in a column with the format I5:

BITVAL(LAST_NAME, 12, 9, 'I5')

For SMITH, the result is 332.

For JONES, the result is 365.

**BYTVAL: Translating a Character to Decimal**

The BYTVAL function translates a character to the ASCII, EBCDIC, or Unicode decimal value that represents it, depending on the operating system.
Syntax: How to Translate a Character

\[
\text{BYTVAL(} \text{character, output) }
\]

where:

- **character**
  - Alphanumeric
  - Is the character to be translated. If you supply more than one character, the function evaluates the first.

- **output**
  - Integer

Example: Translating the First Character of a Field

BYTVAL translates the first character of LAST_NAME into its ASCII decimal value and stores the result in a column with the format I3.

\[
\text{BYTVAL(LAST_NAME, 'I3')}\]

For SMITH, the result is 83.

For JONES the result is 74.

CHKFMT: Checking the Format of a String

The CHKFMT function checks a character string for incorrect characters or character types. It compares each character string to a second string, called a mask, by comparing each character in the first string to the corresponding character in the mask. If all characters in the character string match the characters or character types in the mask, CHKFMT returns the value 0. Otherwise, CHKFMT returns a value equal to the position of the first character in the character string not matching the mask.

If the mask is shorter than the character string, the function checks only the portion of the character string corresponding to the mask. For example, if you are using a four-character mask to test a nine-character string, only the first four characters in the string are checked; the rest are returned as a no match with CHKFMT giving the first non-matching position as the result.
Syntax: How to Check the Format of a Character String

CHKFMT(numchar, source_string, 'mask', output)

where:

numchar
   Integer
   Is the number of characters being compared to the mask.

string
   Alphanumeric
   Is the character string to be checked.

'mask'
   Alphanumeric
   Is the mask, which contains the comparison characters enclosed in single quotation marks.

Some characters in the mask are generic and represent character types. If a character in the string is compared to one of these characters and is the same type, it matches.

Generic characters are:

A is any letter between A and Z (uppercase or lowercase).
9 is any digit between 0–9.
X is any letter between A–Z or any digit between 0-9.
$ is any character.

Any other character in the mask represents only that character. For example, if the third character in the mask is B, the third character in the string must be B to match.

output
   Integer

Example: Checking the Format of a Field

CHKFMT examines EMP_ID for nine numeric characters starting with 11 and stores the result in a column with the format I3.

CHKFMT(9, EMP_ID, '119999999', 'I3')

For 071382660, the result is 1.
For 119265415, the result is 0.
For 23764317, the result is 2.

**CHKNUM: Checking a String for Numeric Format**

The CHKNUM function checks a character string for numeric format. If the string contains a valid numeric format, CHKNUM returns the value 1. If the string contains characters that are not valid in a number, CHKNUM returns zero (0).

**Syntax:**

How to Check the Format of a Character String

\[
\text{CHKNUM(} \text{numchar, source_string, output)}
\]

where:

- **numchar**
  - Integer
  - Is the number of characters in the string.

- **source_string**
  - Alphanumeric
  - Is the character string to be checked.

- **output**
  - Numeric

**Example:**

Checking a String for Numeric Format

CHKNUM examines STR1 for numeric format.

\[
\text{CHKNUM(8, str1, 'II')}\]

For 12345E01, the result is 1.
For ABCDEFG, the result is 0.

**CTRAN: Translating One Character to Another**

The CTRAN function translates a character within a character string to another character based on its decimal value. This function is especially useful for changing replacement characters to unavailable characters, or to characters that are difficult to input or unavailable on your keyboard. It can also be used for inputting characters that are difficult to enter when responding to a Dialogue Manager -PROMPT command, such as a comma or apostrophe. It eliminates the need to enclose entries in single quotation marks (').
To use CTRAN, you must know the decimal equivalent of the characters in internal machine representation. Note that the coding chart for conversion is platform dependent, hence your platform and configuration option determines whether ASCII, EBCDIC, or Unicode coding is used. Printable EBCDIC or ASCII characters and their decimal equivalents are listed in *Character Chart for ASCII and EBCDIC* on page 20.

In Unicode configurations, this function uses values in the range:

- 0 to 255 for 1-byte characters.
- 256 to 65535 for 2-byte characters.
- 65536 to 16777215 for 3-byte characters.
- 16777216 to 4294967295 for 4-byte characters (primarily for EBCDIC).

**Syntax:**

*How to Translate One Character to Another*

```ctran
CTRAN(length, source_string, decimal, decvalue, output)
```

where:

- `length`
  
  Integer
  
  Is the number of characters in the source string.

- `source_string`
  
  Alphanumeric
  
  Is the character string to be translated.

- `decimal`
  
  Integer
  
  Is the ASCII or EBCDIC decimal value of the character to be translated.

- `decvalue`
  
  Integer
  
  Is the ASCII or EBCDIC decimal value of the character to be used as a substitute for `decimal`.

- `output`
  
  Alphanumeric
Example: Translating Spaces to Underscores on an ASCII Platform

CTRAN translates the spaces in ADDRESS_LN3 (ASCII decimal value of 32) to underscores (ASCII decimal value of 95) and stores the result in a column with the format A20.

CTRAN(20, PRODNAME, 32, 95, 'A20')

For RUTHERFORD NJ 07073, the result is RUTHERFORD_NJ_07073_.

For NEW YORK NY 10039, the result is NEW_YORK_NY_10039__.

CTRFLD: Centering a Character String

The CTRFLD function centers a character string within a field. The number of leading spaces is equal to or one less than the number of trailing spaces.

CTRFLD is useful for centering the contents of a field and its report column, or a heading that consists only of an embedded field. HEADING CENTER centers each field value including trailing spaces. To center the field value without the trailing spaces, first center the value within the field using CTRFLD.

Syntax: How to Center a Character String

CTRFLD(source_string, length, output)

where:

source_string
   Alphanumeric
   Is the character string enclosed in single quotation marks, or a field or variable that contains the character string.

length
   Integer
   Is the number of characters in source_string and output. This argument must be greater than 0. A length less than 0 can cause unpredictable results.

output
   Alphanumeric

Example: Centering a Field

CTRFLD centers LAST_NAME and stores the result in a column with the format A12:

CTRFLD(LAST_NAME, 12, 'A12')
EDIT: Extracting or Adding Characters

The EDIT function extracts characters from the source string and adds characters to the output string, according to the mask. It can extract a substring from different parts of the source string. It can also insert characters from the source string into an output string. For example, it can extract the first two characters and the last two characters of a string to form a single output string.

EDIT compares the characters in a mask to the characters in a source string. When it encounters a nine (9) in the mask, EDIT copies the corresponding character from the source field to the output string. When it encounters a dollar sign ($) in the mask, EDIT ignores the corresponding character in the source string. When it encounters any other character in the mask, EDIT copies that character to the corresponding position in the output string. This process ends when the mask is exhausted.

**Note:**
- EDIT does not require an output argument because the result is alphanumeric and its size is determined from the mask value.
- EDIT can also convert the format of a field. For information on converting a field with EDIT, see *EDIT: Converting the Format of a Field* on page 282.

**Syntax:**

**How to Extract or Add Characters**

```plaintext
EDIT(source_string, 'mask');
```

where:

- **source_string**
  - Alphanumeric
  - Is a character string from which to pick characters. Each 9 in the mask represents one digit, so the size of *source_string* must be at least as large as the number of 9's in the mask.

- **mask**
  - Alphanumeric
  - Is a string of mask characters enclosed in single quotation marks. The length of the mask, excluding characters other than 9 and $, determines the length of the output field.

**Example:**

**Extracting Characters**

EDIT extracts the first initials from the FNAME column.

```plaintext
EDIT(FNAME, '9$$$$$$$$$')
```
For GREGORY, the result is G.
For STEVEN, the result is S.

**GETTOK: Extracting a Substring (Token)**

The GETTOK function divides a character string into substrings, called tokens. The data must have a specific character, called a delimiter, that occurs in the string and separates the string into tokens. GETTOK returns the token specified by the `token_number` argument. GETTOK ignores leading and trailing blanks in the source character string.

For example, suppose you want to extract the fourth word from a sentence. In this case, use the space character for a delimiter and the number 4 for `token_number`. GETTOK divides the sentence into words using this delimiter, then extracts the fourth word. If the string is not divided by the delimiter, use the PARAG function for this purpose. See *PARAG: Dividing Text Into Smaller Lines* on page 121.

**Syntax:** How to Extract a Substring (Token)

```
GETTOK(source_string, inlen, token_number, 'delim', outlen, output)
```

where:

- `source_string`  
  Alphanumeric
  Is the source string from which to extract the token.

- `inlen`  
  Integer
  Is the number of characters in `source_string`. If this argument is less than or equal to 0, the function returns spaces.

- `token_number`  
  Integer
  Is the number of the token to extract. If this argument is positive, the tokens are counted from left to right. If this argument is negative, the tokens are counted from right to left. For example, -2 extracts the second token from the right. If this argument is 0, the function returns spaces. Leading and trailing null tokens are ignored.
'delim'
    Alphanumeric
    Is the delimiter in the source string enclosed in single quotation marks. If you specify more
    than one character, only the first character is used.

outlen
    Integer
    Is the size of the token extracted. If this argument is less than or equal to 0, the function
    returns spaces. If the token is longer than this argument, it is truncated; if it is shorter, it
    is padded with trailing spaces.

output
    Alphanumeric
    Note that the delimiter is not included in the extracted token.

Example: Extracting a Token
GETTOK extracts the last token from ADDRESS_LN3 and stores the result in a column with the
format A10:

GETTOK(ADDRESS_LN3, 20, -1, ' ', 10, 'A10')

In this case, the last token will be the ZIP code.
For RUTHERFORD NJ 07073, the result is 07073.
For NEW YORK NY 10039, the result is 10039.

LCWORD: Converting a String to Mixed-Case

The LCWORD function converts the letters in a character string to mixed-case. It converts every
alphanumeric character to lowercase except the first letter of each new word and the first letter
after a single or double quotation mark, which it converts to uppercase. For example,
O'CONNOR is converted to O'Connor and JACK'S to Jack'S.

LCWORD skips numeric and special characters in the source string and continues to convert
the following alphabetic characters. The result of LCWORD is a string in which the initial
uppercase characters of all words are followed by lowercase characters.
Syntax: How to Convert a Character String to Mixed-Case

\[ \text{LCWORD}(\text{length}, \text{source \_string}, \text{output}) \]

where:

\text{length}  
Integer  
Is the number of characters in \text{source \_string} and \text{output}.

\text{string}  
Alphanumeric  
Is the character string to be converted.

\text{output}  
Alphanumeric

Example: Converting a Character String to Mixed-Case

LCWORD converts \text{LAST \_NAME} to mixed-case and stores the result in a column with the format A15:

\[ \text{LCWORD}(15, \text{LAST \_NAME}, '\text{A15}') \]

For \text{STEVENS}, the result is Stevens.
For \text{SMITH}, the result is Smith.

\text{LCWORD2: Converting a String to Mixed-Case}

The \text{LCWORD2} function converts the letters in a character string to mixed-case by converting the first letter of each word to uppercase and converting every other letter to lowercase. In addition, a double quotation mark or a space indicates that the next letter should be converted to uppercase.

For example, "\text{SMITH}" would be changed to "Smith" and "\text{JACK S}" would be changed to "Jack S".
**Syntax: How to Convert a Character String to Mixed-Case**

\[
\text{LCWORD2}(\text{length}, \text{string}, \text{output})
\]

where:

- `length`  
  Integer  
  Is the length, in characters, of the character string or field to be converted, or a field that contains the length.

- `string`  
  Alphanumeric  
  Is the character string to be converted, or a temporary field that contains the string.

- `output`  
  Alphanumeric  
  The length must be greater than or equal to `length`.

**Example: Converting a Character String to Mixed-Case**

LCWORD2 converts the string O’CONNOR’s to mixed-case:

The value returned is O’Connor’s.

**LCWORD3: Converting a String to Mixed-Case**

The LCWORD3 function converts the letters in a character string to mixed-case by converting the first letter of each word to uppercase and converting every other letter to lowercase. In addition, a single quotation mark indicates that the next letter should be converted to uppercase, as long as it is neither followed by a blank nor the last character in the input string.

For example, 'SMITH' would be changed to 'Smith' and JACK’S would be changed to Jack’s.

**Syntax: How to Convert a Character String to Mixed-Case Using LCWORD3**

\[
\text{LCWORD3}(\text{length}, \text{string}, \text{output})
\]

where:

- `length`  
  Integer  
  Is the length, in characters, of the character string or field to be converted, or a field that contains the length.
**string**
Alphanumeric

Is the character string to be converted, or a field that contains the string.

**output**
Alphanumeric

The length must be greater than or equal to length.

**Example:** Converting a Character String to Mixed-Case Using LCWORD3

For the string O'CONNOR’s, LCWORD3 returns O'Connor's.

For the string o'connor’s, LCWORD3 also returns O'Connor's.

**LJUST: Left-Justifying a String**

LJUST left-justifies a character string.

**Syntax:** How to Left-Justify a Character String

LJUST(length, source_string, output)

where:

**length**
Integer

Is the number of characters in source_string and output.

**source_string**
Alphanumeric

Is the character string to be justified.

**output**
Alphanumeric

**Example:** Left-Justifying a String

LJUST left-justifies FNAME and stores the result in a column with the format A25:

LJUST(15, FNAME, 'A25')

**LOCASE: Converting Text to Lowercase**

The LOCASE function converts alphanumeric text to lowercase.
**Syntax:** How to Convert Text to Lowercase

\[
\text{LOCASE}(\text{length}, \text{source\_string}, \text{output})
\]

where:

- **length**
  - Integer
  - Is the number of characters in **source\_string** and **output**. The length must be greater than 0.

- **source\_string**
  - Alphanumeric
  - Is the character string to convert.

- **output**
  - Alphanumeric

**Example:** Converting a String to Lowercase

LOCASE converts LAST\_NAME to lowercase and stores the result in a column with the format A15:

\[
\text{LOCASE}(15, \text{LAST\_NAME}, 'A15')
\]

For SMITH, the result is smith.

For JONES, the result is jones.

**OVRLAY: Overlaying a Character String**

The OVRLAY function overlays a base character string with a substring. The function enables you to edit part of an alphanumeric field without replacing the entire field.

**Syntax:** How to Overlay a Character String

\[
\text{OVRLAY}(\text{source\_string}, \text{length}, \text{substring}, \text{sublen}, \text{position}, \text{output})
\]

where:

- **source\_string**
  - Alphanumeric
  - Is the base character string.
**stringlen**

Integer

Is the number of characters in `source_string` and `output`. If this argument is less than or equal to 0, unpredictable results occur.

**substring**

Alphanumeric

Is the substring that will overlay `source_string`.

**sublen**

Integer

Is the number of characters in `substring`. If this argument is less than or equal to 0, the function returns spaces.

**position**

Integer

Is the position in `source_string` at which the overlay begins. If this argument is less than or equal to 0, the function returns spaces. If this argument is larger than `stringlen`, the function returns the source string.

**output**

Alphanumeric

Note that if the overlaid string is longer than the output field, the string is truncated to fit the field.

**Example:** Replacing Characters in a Character String

OVRLAY replaces the last three characters of EMP_ID with CURR_JOBCODE to create a new identification code and stores the result in a column with the format A9:

```
OVRLAY(EMP_ID, 9, CURR_JOBCODE, 3, 7, 'A9')
```

For EMP_ID of 326179357 with CURR_JOBCODE of B04, the result is 26179B04.

For EMP_ID of 818692173 with CURR_JOBCODE of A17, the result is 818692A17.

**PARAG: Dividing Text Into Smaller Lines**

The PARAG function divides a character string into substrings by marking them with a delimiter. It scans a specific number of characters from the beginning of the string and replaces the last space in the group scanned with the delimiter, thus creating a first substring, also known as a token. It then scans the next group of characters in the line, starting from the delimiter, and replaces its last space with a second delimiter, creating a second token. It repeats this process until it reaches the end of the line.
Once each token is marked off by the delimiter, you can use the function GETTOK to place the tokens into different fields (see GETTOK: Extracting a Substring (Token) on page 115). If PARAG does not find any spaces in the group it scans, it replaces the first character after the group with the delimiter. Therefore, make sure that any group of characters has at least one space. The number of characters scanned is provided as the maximum token size.

For example, if you have a field called 'subtitle' which contains a large amount of text consisting of words separated by spaces, you can cut the field into roughly equal substrings by specifying a maximum token size to divide the field. If the field is 350 characters long, divide it into three substrings by specifying a maximum token size of 120 characters. This technique enables you to print lines of text in paragraph form.

**Tip:** If you divide the lines evenly, you may create more sub-lines than you intend. For example, suppose you divide 120-character text lines into two lines of 60 characters maximum, but one line is divided so that the first sub-line is 50 characters and the second is 55. This leaves room for a third sub-line of 15 characters. To correct this, insert a space (using weak concatenation) at the beginning of the extra sub-line, then append this sub-line (using strong concatenation) to the end of the one before it. Note that the sub-line will be longer than 60 characters.

**Syntax:**

How to Divide Text Into Smaller Lines

```
PARAG(length, source_string, 'delimiter', max_token_size, output)
```

where:

- **length**
  
  Integer
  
  Is the number of characters in `source_string` and `output`.

- **source_string**
  
  Alphanumeric
  
  Is a string to divide into tokens.

- **delimiter**
  
  Alphanumeric
  
  Is the delimiter enclosed in single quotation marks. Choose a character that does not appear in the text.

- **max_token_size**
  
  Integer
  
  Is the upper limit for the size of each token.
outputs
Alphanumeric

**Example:** Dividing Text Into Smaller Lines

PARAG divides ADDRESS_LN2 into smaller lines of not more than ten characters, using a comma as the delimiter. The result is stored in a column with the format A20:

```
PARAG(20, ADDRESS_LN2, ',', 10, 'A20')
```

For 147-15 NORTHERN BLD, the result is 147-15,NORTHERN,BLD.

For 13 LINDEN AVE., the result is 13 LINDEN,AVE.

**PATTERN:** Generating a Pattern From a String

The PATTERN function examines a source string and produces a pattern that indicates the sequence of numbers, uppercase letters, and lowercase letters in the source string. This function is useful for examining data to make sure that it follows a standard pattern.

In the output pattern:

- Any character from the input that represents a single-byte digit becomes the character 9.
- Any character that represents an uppercase letter becomes A, and any character that represents a lowercase letter becomes a. For European NLS mode (Western Europe, Central Europe), A and a are extended to apply to accented alphabets.
- For Japanese, double-byte characters and Hankaku-katakana become C (uppercase). Note that double-byte includes Hiragana, Katakana, Kanji, full-width alphabets, full-width numbers, and full-width symbols. This means that all double-byte letters such as Chinese and Korean are also represented as C.
- Special characters remain unchanged.
- An unprintable character becomes the character X.

**Syntax:** How to Generate a Pattern From an Input String

```
PATTERN (length, source_string, output)
```

where:

- **length**
  - Numeric
  - Is the length of source_string.
Example: Producing a Pattern From Alphanumeric Data

PATTERN generates a pattern for each instance of TESTFLD. The result is stored in a column with the format A14:

\[ \text{PATTERN (14, TESTFLD, 'A14')} \]

For 212-736-6250, the result is 999-999-9999.

For 800-969-INFO, the result is 1999-999-AAAA.

POSIT: Finding the Beginning of a Substring

The POSIT function finds the starting position of a substring within a source string. For example, the starting position of the substring DUCT in the string PRODUCTION is 4. If the substring is not in the parent string, the function returns the value 0.

Syntax: How to Find the Beginning of a Substring

\[ \text{POSIT(source_string, length, substring, sublength, output)} \]

where:

\[ \text{source_string} \]
Alphanumeric

Is the string to parse.

\[ \text{length} \]
Integer

Is the number of characters in the source string. If this argument is less than or equal to 0, the function returns a 0.

\[ \text{substring} \]
Alphanumeric

Is the substring whose position you want to find.
**sublength**

Integer

Is the number of characters in *substring*. If this argument is less than or equal to 0, or if it is greater than *length*, the function returns a 0.

**output**

Integer

**Example:** Finding the Position of a Letter

POSIT determines the position of the first capital letter I in LAST_NAME and stores the result in a column with the format I2:

POSIT(LAST_NAME, 15, 'I', 1, 'I2')

For STEVENS, the result is 0.
For SMITH, the result is 3.
For IRVING, the result is 1.

**REVERSE: Reversing the Characters in a String**

The REVERSE function reverses the characters in a string.

**Syntax:** How to Reverse the Characters in a String

REVERSE(*length*, *source_string*, *output*)

where:

*length*

Integer

Is the number of characters in *source_string* and *output*.

*source_string*

Alphanumeric

Is the character string to reverse.

*output*

Alphanumeric
Example: Reversing the Characters in a String

REVERSE reverses the characters in PRODCAT and stores the result in a column with the format A15:

REVERSE(15, PRODCAT, 'A15')

For VCRs, the result is sRCV.
For DVD, the result is DVD.

RJUST: Right-Justifying a Character String

The RJUST function right-justifies a character string. All trailing blanks become leading blanks. This is useful when you display alphanumeric fields containing numbers.

Syntax: How to Right-Justify a Character String

RJUST(length, source_string, output)

where:

length
Integer
Is the number of characters in source_string and output Their lengths must be the same to avoid justification problems.

source_string
Alphanumeric
Is the character string to right justify.

output
Alphanumeric

Example: Right-Justifying a String

RJUST right-justifies LAST_NAME and stores the result in a column with the format A15:

RJUST(15, LAST_NAME, 'A15')

SOUNDEX: Comparing Character Strings Phonetically

The SOUNDEX function analyzes a character string phonetically, without regard to spelling. It converts character strings to four character codes. The first character must be the first character in the string. The last three characters represent the next three significant sounds in the source string.
**Syntax:** How to Compare Character Strings Phonetically

\[
\text{SOUNDEX}(\text{length}, \text{source\_string}, \text{output})
\]

where:

- **length**
  - Alphanumeric
  - Is the number of characters in `source\_string`. The number must be from 01 to 99, expressed with two digits (for example '01'); a number larger than 99 causes the function to return asterisks (*) as output.

- **source\_string**
  - Alphanumeric
  - Is the string to analyze.

- **output**
  - Alphanumeric

**Example:** Comparing Character Strings Phonetically

SOUNDEX analyzes LAST\_NAME phonetically and stores the result in a column with the format A4.

\[
\text{SOUNDEX('15', \text{LAST\_NAME}, 'A4')}
\]

**SPELLNM: Spelling Out a Dollar Amount**

The SPELLNM function spells out an alphanumeric string or numeric value containing two decimal places as dollars and cents. For example, the value 32.50 is THIRTY TWO DOLLARS AND FIFTY CENTS.

**Syntax:** How to Spell Out a Dollar Amount

\[
\text{SPELLNM}(\text{outlength}, \text{number}, \text{output})
\]

where:

- **outlength**
  - Integer
  - Is the number of characters in `output`. 
If you know the maximum value of *number*, use the following table to determine the value of *outlength*:

<table>
<thead>
<tr>
<th>If number is less than...</th>
<th>...outlength should be</th>
</tr>
</thead>
<tbody>
<tr>
<td>$10</td>
<td>37</td>
</tr>
<tr>
<td>$100</td>
<td>45</td>
</tr>
<tr>
<td>$1,000</td>
<td>59</td>
</tr>
<tr>
<td>$10,000</td>
<td>74</td>
</tr>
<tr>
<td>$100,000</td>
<td>82</td>
</tr>
<tr>
<td>$1,000,000</td>
<td>96</td>
</tr>
</tbody>
</table>

*number*
Alphanumeric or Numeric (9.2)

Is the number to be spelled out. This value must contain two decimal places.

*output*
Alphanumeric

**Example:**  Spelling Out a Dollar Amount

SPELLNM spells out the values in CURR_SAL and stores the result in a column with the format A82:

```plaintext
SPELLNM(82, CURR_SAL, 'A82')
```

For $13,200.00, the result is THIRTEEN THOUSAND TWO HUNDRED DOLLARS AND NO CENTS.
For $18,480.00, the result is EIGHTEEN THOUSAND FOUR HUNDRED EIGHTY DOLLARS AND NO CENTS.

**SQUEEZ: Reducing Multiple Spaces to a Single Space**

The SQUEEZ function reduces multiple contiguous spaces within a character string to a single space. The resulting character string has the same length as the original string but is padded on the right with spaces.
**Syntax:** How to Reduce Multiple Spaces to a Single Space

\[
SQUEEZ(length, source_string, output)
\]

where:

- \( length \)  
  Integer  
  Is the number of characters in \( source_string \) and \( output \).

- \( source_string \)  
  Alphanumeric  
  Is the character string to squeeze.

- \( output \)  
  Alphanumeric

**Example:** Reducing Multiple Spaces to a Single Space

SQUEEZ reduces multiple spaces in NAME to a single blank and stores the result in a column with the format A30:

\[
SQUEEZ(30, NAME, 'A30')
\]

For MARY SMITH, the result is MARY SMITH.

For DIANE JONES, the result is DIANE JONES.

For JOHN MCCOY, the result is JOHN MCCOY.

**STRIP: Removing a Character From a String**

The STRIP function removes all occurrences of a specific character from a string. The resulting character string has the same length as the original string but is padded on the right with spaces.

**Syntax:** How to Remove a Character From a String

\[
STRIP(length, source_string, char, output)
\]

where:

- \( length \)  
  Integer  
  Is the number of characters in \( source_string \) and \( output \).
source string
   Alphanumeric
   
   Is the string from which the character will be removed.

char
   Alphanumeric
   
   Is the character to be removed from the string. If more than one character is provided, the
   left-most character will be used as the strip character.

   Note: To remove single quotation marks, use two consecutive quotation marks. You must
   then enclose this character combination in single quotation marks.

output
   Alphanumeric

Example: Removing Occurrences of a Character From a String

STRIP removes all occurrences of a period (.) from DIRECTOR and stores the result in a field
with the format A17:

   STRIP(17, DIRECTOR, '.', 'A17')

For ZEMECKIS R., the result is ZEMECKIS R.

For BROOKS J.L., the result is BROOKS JL.

STRREP: Replacing Character Strings

The STRREP replaces all instances of a specified string within a source string. It also supports
replacement by null strings.

Syntax: How to Replace Character Strings

   STRREP (inlength, instring, searchlength, searchstring, replength, repstring, outlength, output)

   where:

   inlength
      Numeric
      
      Is the number of characters in the source string.

   instring
      Alphanumeric
      
      Is the source string.
searchlength
  Numeric
  Is the number of characters in the (shorter length) string to be replaced.

searchstring
  Alphanumeric
  Is the character string to be replaced.

replength
  Numeric
  Is the number of characters in the replacement string. Must be zero (0) or greater.

repstring
  Alphanumeric
  Is the replacement string (alphanumeric). Ignored if replength is zero (0).

outlength
  Numeric
  Is the number of characters in the resulting output string. Must be 1 or greater.

output
  Alphanumeric

Reference: Usage Note for STRREP Function
The maximum string length is 4095.

Example: Replacing Commas and Dollar Signs
STRREP finds and replaces commas and then dollar signs and stores the result in field with the format A17:

\[
\begin{align*}
\text{STRREP}(15, \text{CS\_ALPHA}, 1, ',', 0, 'X', 14, 'A14') \\
\text{STRREP}(14, \text{CS\_NOCOMMAS}, 1, '$', 4, '\text{USD }', 17, 'A17') \\
\end{align*}
\]

For $29,700.00, the result is USD 29700.00.
For $9,000.00, the result is USD 9000.00.

SUBSTR: Extracting a Substring
The SUBSTR function extracts a substring based on where it begins and its length in the source string.
**Syntax:** How to Extract a Substring

```sql
SUBSTR(length, source_string, start, end, sublength, output)
```

where:

- **length**
  - Integer
  - Is the number of characters in `source_string`.

- **source_string**
  - Alphanumeric
  - Is the string from which to extract a substring.

- **start**
  - Integer
  - Is the starting position of the substring in the source string. If `start` is less than one or greater than `length`, the function returns spaces.

- **end**
  - Integer
  - Is the ending position of the substring. If this argument is less than `start` or greater than `length`, the function returns spaces.

- **sublength**
  - Integer
  - Is the number of characters in the substring (normally `end - start + 1`). If `sublength` is longer than `end - start + 1`, the substring is padded with trailing spaces. If it is shorter, the substring is truncated. This value should be the declared length of `output`. Only `sublength` characters will be processed.

- **output**
  - Alphanumeric
**Example:**  Extracting a String

SUBSTR extracts the first three characters from LAST_NAME, and stores the results in a column with the format A3:

```
SUBSTR(15, LAST_NAME, 1, 3, 'A3')
```

For BANNING, the result is BAN.

For MCKNIGHT, the result is MCK.

**TRIM: Removing Leading and Trailing Occurrences**

The TRIM function removes leading and/or trailing occurrences of a pattern within a character string.

**Syntax:**  How to Remove Leading and Trailing Occurrences

```
TRIM(trim_where, source_string, length, pattern, sublength, output)
```

where:

- **trim_where**
  - Alphanumeric
  - Is one of the following, which indicates where to remove the pattern:
    - 'L' removes leading occurrences.
    - 'T' removes trailing occurrences.
    - 'B' removes both leading and trailing occurrences.

- **source_string**
  - Alphanumeric
  - Is the string to trim.

- **string_length**
  - Integer
  - Is the number of characters in the source string.

- **pattern**
  - Alphanumeric
  - Is the character string pattern to remove.
**sublength**
Integer

Is the number of characters in the pattern.

**output**
Alphanumeric

**Example:** Removing Leading Occurrences
TRIM removes leading occurrences of the characters BR from DIRECTOR and stores the result in a column with the format A17:

```plaintext
TRIM('L', DIRECTOR, 17, 'BR', 2, 'A17')
```

For BROOKS R., the result is OOKS R.

For ABRAHAMS J., the result is ABRAHAMS J.

**UPCASE: Converting Text to Uppercase**

The UPCASE function converts a character string to uppercase. It is useful for sorting on a field that contains both mixed-case and uppercase values. Sorting on a mixed-case field produces incorrect results because the sorting sequence in EBCDIC always places lowercase letters before uppercase letters, while the ASCII sorting sequence always places uppercase letters before lowercase. To obtain correct results, define a new field with all of the values in uppercase, and sort on that field.

**Syntax:** How to Convert Text to Uppercase

```plaintext
UPCASE(length, source_string, output)
```

where:

**length**
Integer

Is the number of characters in `source_string` and `output`.

**input**
Alphanumeric

Is the string to convert.
output

Alphanumeric of type AnV or An

If the format of the output_format is AnV, then the length returned is equal to the smaller of the source_string length and the upper_limit length.

Example: Converting a Mixed-Case String to Uppercase

UPCASE converts LAST_NAME_MIXED to uppercase and stores the result in a column with the format A15:

```
UPCASE(15, LAST_NAME_MIXED, 'A15')
```

For Banning, the result is BANNING.

For Mc Knight, the result is MCKNIGHT.

XMLDECOD: Decoding XML-Encoded Characters

The XMLDECOD function decodes the following five standard XML-encoded characters when they are encountered in a string:

<table>
<thead>
<tr>
<th>Character Name</th>
<th>Character</th>
<th>XML-Encoded Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ampersand</td>
<td>&amp;</td>
<td>&amp;</td>
</tr>
<tr>
<td>greater than symbol</td>
<td>&gt;</td>
<td>&gt;</td>
</tr>
<tr>
<td>less than symbol</td>
<td>&lt;</td>
<td>&lt;</td>
</tr>
<tr>
<td>double quotation mark</td>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>single quotation mark (apostrophe)</td>
<td>'</td>
<td>'</td>
</tr>
</tbody>
</table>

Syntax: How to Decode XML-Encoded Characters

```
XMLDECOD(inlength, source_string, outlength, output)
```

where:

*inlength*  
Integer

Is the length of the field containing the source character string, or a field that contains the length.
**source_string**
Alphanumeric

Is the name of the field containing the source character string or the string enclosed in single quotation marks (').

**outlength**
Integer

Is the length of the output character string, or a field that contains the length.

**output**
Integer

**Example:** Decoding XML-Encoded Characters

XMLDECOD decodes XML-encoded characters and stores the output in a string with format A30:

```
XMLDECOD(30, INSTRING, 30, 'A30')
```

For &amp;, the result is &.

For &gt;, the result is >.

**XMLENCOD: XML-Encoding Characters**

The XMLENCOD function encodes the following five standard characters when they are encountered in a string:

<table>
<thead>
<tr>
<th>Character Name</th>
<th>Character</th>
<th>Encoded Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ampersand</td>
<td>&amp;</td>
<td>&amp;</td>
</tr>
<tr>
<td>greater than symbol</td>
<td>&gt;</td>
<td>&gt;</td>
</tr>
<tr>
<td>less than symbol</td>
<td>&lt;</td>
<td>&lt;</td>
</tr>
<tr>
<td>double quotation mark</td>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>single quotation mark (apostrophe)</td>
<td>'</td>
<td>'</td>
</tr>
</tbody>
</table>
**Syntax:**

How to XML-Encode Characters

`XMLENCOD(inlength, source_string, option, outlength, output)`

where:

`inlength`
- Integer
  - Is the length of the field containing the source character string, or a field that contains the length.

`source_string`
- Alphanumeric
  - Is the name of the field containing the source character string or a string enclosed in single quotation marks ('').

`option`
- Integer
  - Is a code that specifies whether to process a string that already contains XML-encoded characters. Valid values are:
    - 0, the default, which cancels processing of a string that already contains at least one XML-encoded character.
    - 1, which processes a string that contains XML-encoded characters.

`outlength`
- Integer
  - Is the length of the output character string, or a field that contains the length.

**Note:** The output length, in the worst case, could be six times the length of the input.

`output`
- Integer

**Example:**

XML-Encoding Characters

`XMLENCOD` XML-encodes characters and stores the output in a string with format A30:

`XMLENCOD(30, INSTRING, 30, 1, 'A30')`

For `&`, the result is `&amp;`.

For `>`, the result is `&gt;`. 
Variable Length Character Functions

The character format AnV is supported in synonyms for FOCUS, XFOCUS, and relational data sources. This format is used to represent the VARCHAR (variable length character) data types supported by relational database management systems.

In this chapter:

- Overview
- LENV: Returning the Length of an Alphanumeric Field
- LOCASV: Creating a Variable Length Lowercase String
- POSITV: Finding the Beginning of a Variable Length Substring
- SUBSTV: Extracting a Variable Length Substring
- TRIMV: Removing Characters From a String
- UPCASV: Creating a Variable Length Uppercase String

Overview

For relational data sources, AnV keeps track of the actual length of a VARCHAR column. This information is especially valuable when the value is used to populate a VARCHAR column in a different RDBMS. It affects whether trailing blanks are retained in string concatenation and, for Oracle, string comparisons (the other relational engines ignore trailing blanks in string comparisons).

In a FOCUS or XFOCUS data source, AnV does not provide true variable length character support. It is a fixed-length character field with an extra two leading bytes to contain the actual length of the data stored in the field. This length is stored as a short integer value occupying two bytes. Because of the two bytes of overhead and the additional processing required to strip them, AnV format is not recommended for use with non-relational data sources.

AnV fields can be used as arguments to all Information Builders-supplied functions that expect alphanumeric arguments. An AnV input parameter is treated as an An parameter and is padded with blanks to its declared size (n). If the last parameter specifies an AnV format, the function result is converted to type AnV with actual length set equal to its size.
The functions described in this topic are designed to work specifically with the AnV data type parameters.

**LENV: Returning the Length of an Alphanumeric Field**

LENV returns the actual length of an AnV field or the size of an An field.

**Syntax:**

How to Find the Length of an Alphanumeric Field

\[
\text{LENV}(\text{source\_string}, \text{output})
\]

where:

- **source\_string**
  Alphanumeric of type An or AnV
  Is the source string or field. If it is an An format field, the function returns its size, \( n \). For a character string enclosed in quotation marks or a variable, the size of the string or variable is returned. For a field of AnV format, its length, taken from the length-in-bytes of the field, is returned.

- **output**
  Integer

**Example:**

Finding the Length of an AnV Field

LENV returns the length of TITLEV and stores the result in a column with the format I2:

\[
\text{LENV}(\text{TITLEV}, \text{'I2'})
\]

For ALICE IN WONDERLAND, the result is 19.

For SLEEPING BEAUTY, the result is 15.

**LOCASV: Creating a Variable Length Lowercase String**

The LOCASV function converts alphabetic characters in the source string to lowercase and is similar to LOCASE. LOCASV returns AnV output whose actual length is the lesser of the actual length of the AnV source string and the value of the input parameter upper\_limit.
**Syntax:** How to Create a Variable Length Lowercase String

LOCASV(upper_limit, source_string, output)

where:

**upper_limit**
Integer

Is the limit for the length of the source string.

**source_string**
Alphanumeric of type An or AnV

Is the string to be converted to lowercase. If it is a field, it can have An or AnV format. If it is a field of type AnV, its length is taken from the length in bytes stored in the field. If **upper_limit** is smaller than the actual length, the source string is truncated to this upper limit.

**output**
Alphanumeric of type An or AnV

If the output format is AnV, the actual length returned is equal to the smaller of the source string length and the upper limit.

**Example:** Creating a Variable Length Lowercase String

LOCASV converts LAST_NAME to lowercase and specifies a length limit of five characters. The results are stored in a column with the format A15V:

LOCASV(5, LAST_NAME, 'A15V')

For SMITH, the result is smith.

For JONES, the result is jones.

**POSITV: Finding the Beginning of a Variable Length Substring**

The POSITV function finds the starting position of a substring within a larger string. For example, the starting position of the substring DUCT in the string PRODUCTION is 4. If the substring is not in the parent string, the function returns the value 0. This is similar to POSIT; however, the lengths of its AnV parameters are based on the actual lengths of those parameters in comparison with two other parameters that specify their sizes.
**Syntax:**

How to Find the Beginning of a Variable Length Substring

POSITV(source_string, upper_limit, substring, sub_limit, output)

where:

**source_string**
Alphanumeric of type An or AnV

Is the source string that contains the substring whose position you want to find. If it is a field of AnV format, its length is taken from the length bytes stored in the field. If upper_limit is smaller than the actual length, the source string is truncated to this upper limit.

**upper_limit**
Integer

Is a limit for the length of the source string.

**substring**
Alphanumeric of type An or AnV

Is the substring whose position you want to find. If it is a field of type AnV, its length is taken from the length bytes stored in the field. If sub_limit is smaller than the actual length, the source string is truncated to this limit.

**sub_limit**
Integer

Is the limit for the length of the substring.

**output**
Integer

**Example:**

Finding the Starting Position of a Variable Length Pattern

POSITV finds the starting position of a comma in TITLEV, which would indicate a trailing definite or indefinite article in a movie title (such as " , THE" in SMURFS, THE). LENV is used to determine the length of title. The result is stored in a column with the format I4:

POSITV(TITLEV, LENV(TITLEV, 'I4'), ', ', 1, 'I4')

For “SMURFS, THE”, the result is 7.

For “SHAGGY DOG, THE”, the result is 11.
**SUBSTV: Extracting a Variable Length Substring**

The SUBSTV function extracts a substring from a string and is similar to SUBSTR. However, the end position for the string is calculated from the starting position and the substring length. Therefore, it has fewer parameters than SUBSTR. Also, the actual length of the output field, if it is an AnV field, is determined based on the substring length.

**Syntax:**

How to Extract a Variable Length Substring

\[ \text{SUBSTV}(\text{upper\_limit}, \text{source\_string}, \text{start}, \text{sub\_limit}, \text{output}) \]

where:

- **upper\_limit**
  - Integer
  - Is the limit for the length of the source string.

- **source\_string**
  - Alphanumeric of type An or AnV
  - Is the character string that contains the substring you want to extract. If it is a field of type AnV, its length is taken from the length bytes stored in the field. If **upper\_limit** is smaller than the actual length, the source string is truncated to the upper limit. The final length value determined by this comparison is referred to as **p\_length** (see the description of the **output** parameter for related information).

- **start**
  - Integer
  - Is the starting position of the substring in the source string. The starting position can exceed the source string length, which results in spaces being returned.

- **sub\_limit**
  - Integer
  - Is the length, in characters, of the substring. Note that the ending position can exceed the input string length depending on the provided values for **start** and **sub\_limit**.

- **output**
  - Alphanumeric of type An or AnV
  - If the format of **output** is AnV, and assuming **end** is the ending position of the substring, the actual length, **outlen**, is computed as follows from the values for **end**, **start**, and **p\_length** (see the **source\_string** parameter for related information):
    - If **end** > **p\_length** or **end** < **start**, then **outlen** = 0. Otherwise, **outlen** = **end** - **start** + 1.
**Example:** Extracting a Variable Length Substring

SUBSTV extracts the first three characters from the TITLEV and stores the result in a column with the format A20V:

```plaintext
SUBSTV(39, TITLEV, 1, 3, 'A20V')
```

For SMURFS, the result is SMU.

For SHAGGY DOG, the result is SHA.

**TRIMV: Removing Characters From a String**

The TRIMV function removes leading and/or trailing occurrences of a pattern within a character string. TRIMV is similar to TRIM. However, TRIMV allows the source string and the pattern to be removed to have AnV format.

TRIMV is useful for converting an An field to an AnV field (with the length in bytes containing the actual length of the data up to the last non-blank character).

**Syntax:** How to Remove Characters From a String

```plaintext
TRIMV(trim_where, source_string, upper_limit, pattern, pattern_limit, output)
```

where:

- **trim_where**
  - Alphanumeric
  - Is one of the following, which indicates where to remove the pattern:
    - 'L' removes leading occurrences.
    - 'T' removes trailing occurrences.
    - 'B' removes both leading and trailing occurrences.

- **source_string**
  - Alphanumeric of type An or AnV
  - Is the source string to be trimmed. If it is a field of type AnV, its length is taken from the length in bytes stored in the field. If `upper_limit` is smaller than the actual length, the source string is truncated to this upper limit.

- **upper_limit**
  - Integer
  - Is the upper limit for the length of the source string.
**pattern**
Alphanumeric of type An or AnV

Is the pattern to remove. If it is a field of type AnV, its length is taken from the length in bytes stored in the field. If `pattern_limit` is smaller than the actual length, the pattern is truncated to this limit.

**plength_limit**
Integer

Is the limit for the length of the pattern.

**output**
Alphanumeric of type An or AnV

If the output format is AnV, the length is set to the number of characters left after trimming.

**Example:** Creating an AnV Field by Removing Trailing Blanks

TRIMV removes trailing blanks from TITLE and stores the result in a column with the format A39V:

\[ \text{TRIMV('T', TITLE, 39, ' ', 1, 'A39V')} \]

**UPCASV:** Creating a Variable Length Uppercase String

UPCASV converts alphabetic characters to uppercase, and is similar to UPCASE. However, UPCASV can return AnV output whose actual length is the lesser of the actual length of the AnV source string and an input parameter that specifies the upper limit.

**Syntax:** How to Create a Variable Length Uppercase String

\[ \text{UPCASV(upper_limit, source_string, output)} \]

where:

**upper_limit**
Integer

Is the limit for the length of the source string.

**source_string**
Alphanumeric of type An or AnV

is the string to convert to uppercase. If it is a field of type AnV, its length is taken from the length in bytes stored in the field. If `upper_limit` is smaller than the actual length, the source string is truncated to the upper limit.
**output**
Alphanumeric of type An or AnV

If the output format is AnV, the length returned is equal to the smaller of the source string length and *upper_limit*.

**Example:**  Creating a Variable Length Uppercase String

UPCASEV converts LAST_NAME_MIXED to uppercase and stores the result in a column with the format A15V:

```
UPCASEV(15, LAST_NAME_MIXED, 'A15V5')
```

For Banning, the result is BANNING.

For McKnight, the result is MCKNIGHT.
The functions in this topic manipulate strings of DBCS and SBCS characters when your configuration uses a DBCS code page.

In this chapter:

- **DCTRAN: Translating A Single-Byte or Double-Byte Character to Another**
- **DEDIT: Extracting or Adding Characters**
- **DSTRIP: Removing a Single-Byte or Double-Byte Character From a String**
- **DSUBSTR: Extracting a Substring**
- **JPTRANS: Converting Japanese Specific Characters**
- **KKFCUT: Truncating a String**
- **SFTDEL: Deleting the Shift Code From DBCS Data**
- **SFTINS: Inserting the Shift Code Into DBCS Data**

---

**DCTRAN: Translating A Single-Byte or Double-Byte Character to Another**

The DCTRAN function translates a single-byte or double-byte character within a character string to another character based on its decimal value. To use DCTRAN, you need to know the decimal equivalent of the characters in internal machine representation.

The DCTRAN function can translate single-byte to double-byte characters and double-byte to single-byte characters, as well as single-byte to single-byte characters and double-byte to double-byte characters.

**Syntax:**

```
DCTRAN(length, source_string, indecimal, outdecimal, output)
```

where:

- `length` 
  Double

---

Functions Reference 147
Is the number of characters in \textit{source\_string}.

\textbf{source\_string}

Alphanumeric

Is the character string to be translated.

\textbf{indecimal}

Double

Is the ASCII or EBCDIC decimal value of the character to be translated.

\textbf{outdecimal}

Double

Is the ASCII or EBCDIC decimal value of the character to be used as a substitute for \textit{indecimal}.

\textbf{output}

Alphanumeric

\textit{Example: Using DCTRAN to Translate Double-Byte Characters}

In the following:

\begin{verbatim}
DCTRAN(8, 'AFA本B語', 177, 70, A8)
\end{verbatim}

For \textit{AFA本B語}, the result is \textit{AFA本B語}.

\textbf{DEDIT: Extracting or Adding Characters}

If your configuration uses a DBCS code page, you can use the DEDIT function to extract characters from or add characters to a string.

DEDIT works by comparing the characters in a mask to the characters in a source field. When it encounters a nine (9) in the mask, DEDIT copies the corresponding character from the source field to the new field. When it encounters a dollar sign ($) in the mask, DEDIT ignores the corresponding character in the source field. When it encounters any other character in the mask, DEDIT copies that character to the corresponding position in the new field.
**Syntax:**

How to Extract or Add DBCS or SBCS Characters

\[ \text{DEDIT}(\text{inlength}, \text{source_string}, \text{mask_length}, \text{mask}, \text{output}) \]

where:

- **inlength**
  - Integer
  - Is the number of bytes in `source_string`. The string can have a mixture of DBCS and SBCS characters. Therefore, the number of bytes represents the maximum number of characters possible in the source string.

- **source_string**
  - Alphanumeric
  - Is the string to edit.

- **mask_length**
  - Integer
  - Is the number of characters in mask.

- **mask**
  - Alphanumeric
  - Is the string of mask characters.
  - Each nine (9) in the mask causes the corresponding character from the source field to be copied to the new field.
  - Each dollar sign ($) in the mask causes the corresponding character in the source field to be ignored.
  - Any other character in the mask is copied to the new field.

- **output**
  - Alphanumeric

**Example:** Adding and Extracting DBCS Characters

The following example copies alternate characters from the source string to the new field, starting with the first character in the source string, and then adds several new characters at the end of the extracted string:

\[ \text{DEDIT}(15, \text{あいうえお}, 16, '9$9$9$9$-かきけこ', 'A30') \]

The result is あいうえお-かきけこ.
The following example copies alternate characters from the source string to the new field, starting with the second character in the source string, and then adds several new characters at the end of the extracted string:

```
DEDIT(15, 'あいうえお', 16, '$9$9$9$9$9-ABCDE', 'A20')
The result is aieoe-ABCDE.
```

### DSTRIP: Removing a Single-Byte or Double-Byte Character From a String

The DSTRIP function removes all occurrences of a specific single-byte or double-byte character from a string. The resulting character string has the same length as the original string, but is padded on the right with spaces.

**Syntax:**

**How to Remove a Single-Byte or Double-Byte Character From a String**

```
DSTRIP(length, source_string, char, output)
```

where:

- **length**
  - Double
  - Is the number of characters in `source_string` and `outfield`.

- **source_string**
  - Alphanumeric
  - Is the string from which the character will be removed.

- **char**
  - Alphanumeric
  - Is the character to be removed from the string. If more than one character is provided, the left-most character will be used as the strip character.

**Note:** To remove single quotation marks, use two consecutive quotation marks. You must then enclose this character combination in single quotation marks.

- **output**
  - Alphanumeric
**Example:** Removing a Double-Byte Character From a String

In the following:

\[ \text{DSUBSTR}(9, 'A 日A本B語', '日', A9) \]

For A 日A本B語, the result is AA本B語.

**DSUBSTR: Extracting a Substring**

If your configuration uses a DBCS code page, you can use the DSUBSTR function to extract a substring based on its length and position in the source string.

**Syntax:** How to Extract a Substring

\[ \text{DSUBSTR}(\text{inlength}, \text{source_string}, \text{start}, \text{end}, \text{sublength}, \text{output}) \]

where:

- **inlength**
  - Integer
  - Is the length of the source string in bytes. The string can have a mixture of DBCS and SBCS characters. Therefore, the number of bytes represents the maximum number of characters possible in the source string.

- **source_string**
  - Alphanumeric
  - Is the string from which the substring will be extracted.

- **start**
  - Integer
  - Is the starting position (in number of characters) of the substring in the source string. If this argument is less than one or greater than \( \text{end} \), the function returns spaces.

- **end**
  - Integer
  - Is the ending position (in number of characters) of the substring. If this argument is less than \( \text{start} \) or greater than \( \text{inlength} \), the function returns spaces.
$sublength$

Integer

Is the length of the substring, in characters (normally $end - start + 1$). If $sublength$ is longer than $end - start +1$, the substring is padded with trailing spaces. If it is shorter, the substring is truncated. This value should be the declared length of $output$. Only $sublength$ characters will be processed.

$output$

Alphanumeric

**Example:** Extracting a Substring

The following example extracts the 3-character substring in positions 4 through 6 from a 15-byte string of characters:

```
DSUBSTR( 15, 'あいうえお', 4, 6, 3, 'A10')
```

The result is いう.

*length*

Integer

Is the number of characters in the source_string.

*source_string*

Alphanumeric

Is the string to convert.

*output_format*

Alphanumeric

Is the name of the field that contains the output, or the format enclosed in single quotation marks ('').

**Example:** Using the JPTRANS Function

```
JPTRANS('UPCASE', 20, Alpha_DBCS_Field, 'A20')
```

For a b c, the result is A B C.
JPTTRANS: Converting Japanese Specific Characters

JPTTRANS('LOCASE', 20, Alpha_DBCS_Field, 'A20')
For A B C, the result is a b c.

JPTTRANS('HNZNALPHA', 20, Alpha_SBCS_Field, 'A20')
For AaBbCc123, the result is A a B b C c 1 2 3.

JPTTRANS('HNZNSIGN', 20, Symbol_SBCS_Field, 'A20')
For !@#$％,．？, the result is ! @ $ %、．？

JPTTRANS('HNZNKANA', 20, Hankaku_Katakana_Field, 'A20')
For 「ハ・スホ・ル。」, the result is 「ベースボール。」

JPTTRANS('ZNHNALPHA', 20, Alpha_DBCS_Field, 'A20')
For アイウ, the result is ア イ ウ

JPTTRANS('ZNHNALPHA', 20, Alpha_DBCS_Field, 'A20')
For A a B b C c 1 2 3, the result is AaBbCc123.

JPTTRANS('ZNHNSIGN', 20, Symbol_DBCS_Field, 'A20')
For !@#$％,．？, the result is !@#$％,．？

JPTTRANS('ZNHNKANA', 20, Zenkaku_Katakana_Field, 'A20')
For 「ベースボール。」, the result is 「ベースボール。」

JPTTRANS('HIRAKATA', 20, Hiragana_Field, 'A20')
For アイウ, the result is アイウ

JPTTRANS('HIRAKATA', 20, Hiragana_Field, 'A20')
For あいう, the result is アイウ
JPTRANS('KATAHIRA', 20, Zenkaku_Katakana_Field, 'A20')

For イウ, the result is あいう

In the following, codepoints 0x62 0x63 0x64 are converted to 0x81 0x82 0x83, respectively:

JPTRANS('930TO939', 20, CP930_Field, 'A20')

In the following, codepoints 0x59 0x62 0x63 are converted to 0x81 0x82 0x83, respectively:

JPTRANS('939TO930', 20, CP939_Field, 'A20')

Reference: Usage Notes for the JPTRANS Function

- HNZNSIGN and ZNHNSIGN focus on the conversion of symbols.

Many symbols have a one-to-one relation between Japanese Fullwidth characters and ASCII symbols, whereas some characters have one-to-many relations. For example, the Japanese punctuation character (U+3001) and Fullwidth comma , (U+FF0C) will be converted to the same comma , (U+002C). The following EXTRA rule for those special cases is shown below:

HNZNSIGN:

- Double Quote " (U+0022) -> Fullwidth Right Double Quote " (U+201D)
- Single Quote ' (U+0027) -> Fullwidth Right Single Quote ’ (U+2019)
- Comma , (U+002C) -> Fullwidth Ideographic Comma (U+3001)
- Full Stop . (U+002E) -> Fullwidth Ideographic Full Stop ? (U+3002)
- Backslash \ (U+005C) -> Fullwidth Backslash \ (U+FF3C)
- Halfwidth Left Corner Bracket (U+FF62) -> Fullwidth Left Corner Bracket (U+300C)
- Halfwidth Right Corner Bracket (U+FF63) -> Fullwidth Right Corner Bracket (U+300D)
- Halfwidth Katakana Middle Dot . (U+FF65) -> Fullwidth Middle Dot · (U+30FB)

ZNHNSIGN:

- Fullwidth Right Double Quote " (U+201D) -> Double Quote " (U+0022)
- Fullwidth Left Double Quote “ (U+201C) -> Double Quote " (U+0022)
- Fullwidth Quotation " (U+FF02) -> Double Quote " (U+0022)
- Fullwidth Right Single Quote ’ (U+2019) -> Single Quote ’ (U+0027)
Fullwidth Left Single Quote ' (U+2018) -> Single Quote ' (U+0027)

Fullwidth Single Quote ' (U+FF07) -> Single Quote ' (U+0027)

Fullwidth Ideographic Comma (U+3001) -> Comma , (U+002C)

Fullwidth Comma , (U+FF0C) -> Comma , (U+002C)

Fullwidth Ideographic Full Stop ? (U+3002) -> Full Stop . (U+002E)

Fullwidth Full Stop . (U+FF0E) -> Full Stop . (U+002E)

Fullwidth Yen Sign ¥ (U+FFE5) -> Yen Sign ¥ (U+00A5)

Fullwidth Backslash \ (U+FF3C) -> Backslash \ (U+005C)

Fullwidth Left Corner Bracket (U+300C) -> Halfwidth Left Corner Bracket (U+FF62)

Fullwidth Right Corner Bracket (U+300D) -> Halfwidth Right Corner Bracket (U+FF63)

Fullwidth Middle Dot · (U+30FB) -> Halfwidth Katakana Middle Dot · (U+FF65)

HNZNKANA and ZNHNKANA focus on the conversion of Katakana

They convert not only letters, but also punctuation symbols on the following list:

Fullwidth Ideographic Comma (U+3001) <-> Halfwidth Ideographic Comma (U+FF64)

Fullwidth Ideographic Full Stop (U+3002) <-> Halfwidth Ideographic Full Stop (U+FF61)

Fullwidth Left Corner Bracket (U+300C) <-> Halfwidth Left Corner Bracket (U+FF62)

Fullwidth Right Corner Bracket (U+300D) <-> Halfwidth Right Corner Bracket (U+FF63)

Fullwidth Middle Dot · (U+30FB) <-> Halfwidth Katakana Middle Dot · (U+FF65)

Fullwidth Prolonged Sound (U+30FC) <-> Halfwidth Prolonged Sound (U+FF70)

JPTRANS can be nested for multiple conversions.

For example, text data may contain fullwidth numbers and fullwidth symbols. In some situations, they should be cleaned up for ASCII numbers and symbols.

For バンゴウ # 1 2 3 , the result is バンゴウ#123

JPTRANS('ZNHNALPHA', 20, JPTRANS('ZNHNNSIGN', 20, Symbol_DBCS_Field, 'A20'), 'A20')

HNZNSPACE and ZNHNSPACE focus on the conversion of a space (blank character).
Currently only conversion between U+0020 and U+3000 is supported.

**KKFCUT: Truncating a String**

If your configuration uses a DBCS code page, you can use the KKFCUT function to truncate a string.

**Syntax:**

How to Truncate a String

\[
\text{KKFCUT}(\text{length, source_string, output})
\]

where:

- **length**
  - Integer
  - Is the length of the source string in bytes. The string can have a mixture of DBCS and SBCS characters. Therefore, the number of bytes represents the maximum number of characters possible in the source string.

- **source_string**
  - Alphanumeric
  - Is the string that will be truncated.

- **output**
  - Alphanumeric
  - The string will be truncated to the number of bytes in the output field.

**Example:**

Truncating a String

In the following, KKFCUT truncates the COUNTRY field (up to 10 bytes long) to A4 format:

\[
\text{COUNTRY\_CUT/A4} = \text{KKFCUT}(10, \text{COUNTRY, 'A4'});
\]

The output in ASCII environments is shown in the following image:

<table>
<thead>
<tr>
<th>国名</th>
<th>COUNTRY_CUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>イギリス</td>
<td>イギ</td>
</tr>
<tr>
<td>日本</td>
<td>日本</td>
</tr>
<tr>
<td>イタリア</td>
<td>イタ</td>
</tr>
<tr>
<td>ドイツ</td>
<td>ドイ</td>
</tr>
<tr>
<td>フランス</td>
<td>フラ</td>
</tr>
</tbody>
</table>
The output in EBCDIC environments is shown in the following image:

<table>
<thead>
<tr>
<th>国名</th>
<th>COUNTRY_CUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>日本</td>
<td>日</td>
</tr>
<tr>
<td>イタリア</td>
<td>イ</td>
</tr>
<tr>
<td>ドイツ</td>
<td>ド</td>
</tr>
<tr>
<td>フランス</td>
<td>フ</td>
</tr>
</tbody>
</table>

**SFTDEL: Deleting the Shift Code From DBCS Data**

If your configuration uses a DBCS code page, you can use the SFTDEL function to delete the shift code from DBCS data.

**Syntax:**

How to Delete the Shift Code From DBCS Data

\[
\text{SFTDEL}(\text{source\_string}, \text{length}, \text{output})
\]

where:

- **source\_string**
  - Alphanumeric
  - Is the string from which the shift code will be deleted.

- **length**
  - Integer
  - Is the length of the source string in bytes. The string can have a mixture of DBCS and SBCS characters. Therefore, the number of bytes represents the maximum number of characters possible in the source string.

- **output**
  - Alphanumeric

**Example:**

Deleting the Shift Code From a String

In the following, SFTDEL deleted the shift code from the COUNTRY field (up to 10 bytes long):

\[
\text{COUNTRY\_DEL/A10} = \text{SFTDEL(COUNTRY, 10, 'A10')};
\]
SFTINS: Inserting the Shift Code Into DBCS Data

If your configuration uses a DBCS code page, you can use the SFTINS function to insert the shift code into DBCS data.

**Syntax:**

How to Insert the Shift Code Into DBCS Data

SFTINS(source_string, length, output)

where:

source_string

Alphanumeric

Is the string into which the shift code will be inserted.

length

Integer

Is the length of the source string in bytes. The string can have a mixture of DBCS and SBCS characters. Therefore, the number of bytes represents the maximum number of characters possible in the source string.
Example: SFTINS: Inserting the Shift Code Into a String

In the following example, SFTINS inserts the shift code into the COUNTRY_DEL field (which is the COUNTRY field with the shift code deleted):

\[
\text{COUNTRY_INS}/A10 = \text{SFTINS(COUNTRY_DEL, 10, 'A10')};
\]

The output displays the original COUNTRY field, the COUNTRY_DEL field with the shift code deleted, and the COUNTRY_INS field with the shift code re-inserted.

The output in ASCII environments, is shown in the following image:

<table>
<thead>
<tr>
<th>国名</th>
<th>COUNTRY_DEL</th>
<th>COUNTRY_INS</th>
</tr>
</thead>
<tbody>
<tr>
<td>イギリス</td>
<td>イギリス</td>
<td>イギリス</td>
</tr>
<tr>
<td>日本</td>
<td>日本</td>
<td>日本</td>
</tr>
<tr>
<td>イタリア</td>
<td>イタリア</td>
<td>イタリア</td>
</tr>
<tr>
<td>ドイツ</td>
<td>ドイツ</td>
<td>ドイツ</td>
</tr>
<tr>
<td>フランス</td>
<td>フランス</td>
<td>フランス</td>
</tr>
</tbody>
</table>

The output in EBCDIC environments is shown in the following image:

<table>
<thead>
<tr>
<th>国名</th>
<th>COUNTRY_DEL</th>
<th>COUNTRY_INS</th>
</tr>
</thead>
</table>
| イギリス | バ"
| 日本 | イ
| イタリア | バ"
| ドイツ | バ"
| フランス | バ"
Data Source and Decoding Functions

Data source and decoding functions search for data source records, retrieve data source records or values, and assign values based on the value of an input field.

In this chapter:

- CHECKMD5: Computing an MD5 Hash Check Value
- CHECKSUM: Computing a Hash Sum
- COALESCE: Returning the First Non-Missing Value
- DB_EXPR: Inserting an SQL Expression Into a Request
- DB_INFILE: Testing Values Against a File or an SQL Subquery
- DB_LOOKUP: Retrieving Data Source Values
- DECODE: Decoding Values
- FIND: Verifying the Existence of a Value in a Data Source
- IMPUTE: Replacing Missing Values With Aggregated Values
- LAST: Retrieving the Preceding Value
- LOOKUP: Retrieving a Value From a Cross-referenced Data Source
- NULLIF: Returning a Null Value When Parameters Are Equal

CHECKMD5: Computing an MD5 Hash Check Value

CHECKMD5 takes an alphanumeric input value and returns a 128-bit value in a fixed length alphanumeric string, using the MD5 hash function. A hash function is any function that can be used to map data of arbitrary size to data of fixed size. The values returned by a hash function are called hash values. They can be used for assuring the integrity of transmitted data.

Syntax: How to Compute an MD5 Hash Check Value

```plaintext
CHECKMD5(buffer)
```
where:

buffer

Is a data buffer whose hash value is to be calculated. It can be a set of data of different types presented as a single field, or a group field in one of the following data type formats: An, AnV, or TXn.

**Example: Calculating an MD5 Hash Check Value**

CHECKMD5 calculates a fixed length MD5 hash check value, and HEXTYPE converts it to a printable hexadecimal string.

HEXTYPE(CHECKMD5(PRODUCT_CATEGORY))

For Accessories, the result is 98EDB85B00D9527AD5ACEBE451B3FAE6.

**CHECKSUM: Computing a Hash Sum**

CHECKSUM computes a hash sum, called the checksum, of its input parameter, as a whole number in format I11. This can be used for equality search of the fields. A checksum is a hash sum used to ensure the integrity of a file after it has been transmitted from one storage device to another.

**Syntax:**  How to Compute a CHECKSUM Hash Value

CHECKSUM(buffer)

where:

buffer

Is a data buffer whose hash index is to be calculated. It can be a set of data of different types presented as a single field, in one of the following data type formats: An, AnV, or TXn.

**Example: Calculating a CHECKSUM Hash Value**

CHECKSUM calculates a checksum hash value.

CHECKSUM(PRODUCT_CATEGORY)

For Accessories, the result is -830549649.
**COALESCE: Returning the First Non-Missing Value**

Given a list of arguments, COALESCE returns the value of the first argument that is not missing. If all argument values are missing, it returns a missing value if MISSING is ON. Otherwise it returns a default value (zero or blank).

**Syntax:** How to Return the First Non-Missing Value

\[
\text{COALESCE}(\text{arg1, arg2, ...})
\]

where:

\[
\text{arg1, arg2, ...}
\]

Any field, expression, or constant. The arguments should all be either numeric or alphanumeric.

Are the input parameters that are tested for missing values.

The output data type is the same as the input data types.

**Example:** Returning the First Non-Missing Value

COALESCE returns the first non-missing value:

\[
\text{COALESCE(DAMAGED, RETURNS)}
\]

The following table shows sample inputs and results.

<table>
<thead>
<tr>
<th>DAMAGED</th>
<th>RETURNS</th>
<th>RESULT</th>
</tr>
</thead>
<tbody>
<tr>
<td>MISSING</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>4</td>
<td>6</td>
</tr>
</tbody>
</table>

**DB_EXPR: Inserting an SQL Expression Into a Request**

The DB_EXPR function inserts a native SQL expression exactly as entered into the native SQL generated for a FOCUS or SQL language request.

The DB_EXPR function can be used in a DEFINE command, a DEFINE in a Master File, a WHERE clause, a FILTER FILE command, a filter in a Master File, or in an SQL statement. It can be used in a COMPUTE command if the request is an aggregate request (uses the SUM, WRITE, or ADD command) and has a single display command. The expression must return a single value.
**Syntax:** How to Insert an SQL Expression Into a Request With DB_EXPR

```
DB_EXPR(native_SQL_expression)
```

where:

- **native_SQL_expression**
  
  Is a partial native SQL string that is valid to insert into the SQL generated by the request. The SQL string must have double quotation marks (") around each field reference, unless the function is used in a DEFINE with a WITH phrase.

**Reference:** Usage Notes for the DB_EXPR Function

- The expression must return a single value.
- Any request that includes one or more DB_EXPR functions must be for a synonym that has a relational SUFFIX.
- Field references in the native SQL expression must be within the current synonym context.
- The native SQL expression must be coded inline. SQL read from a file is not supported.

**Example:** Inserting the DB2 BIGINT and CHAR Functions Into a TABLE Request

The following TABLE request against the WF_RETAIL data source uses the DB_EXPR function in the COMPUTE command to call two DB2 functions. It calls the BIGINT function to convert the squared revenue to a BIGINT data type, and then uses the CHAR function to convert that value to alphanumeric.

```
TABLE FILE WF
SUM REVENUE NOPRINT
AND COMPUTE BIGREV/A31 = DB_EXPR(CHAR(BIGINT("REVENUE" * "REVENUE")));
AS 'Alpha Square Revenue'
BY REGION
ON TABLE SET PAGE NOPAGE
END
```
The trace shows that the expression from the DB_EXPR function was inserted into the DB2 SELECT statement:

```sql
SELECT
T11."REGION",
    SUM(T1."Revenue")
   , ((CHAR(BIGINT( SUM(T1."Revenue") * SUM(T1."Revenue") ) ) )
FROM
wrd_fact_sales T1,
wrd_dim_customer T5,
wrd_dim_geography T11
WHERE
(T5."ID_CUSTOMER" = T1."ID_CUSTOMER") AND
(T11."ID_GEOGRAPHY" = T5."ID_GEOGRAPHY")
GROUP BY
T11."REGION  
ORDER BY
T11."REGION  
FOR FETCH ONLY;
END
```

**DB_INFILE: Testing Values Against a File or an SQL Subquery**

The DB_INFILE function compares one or more field values in a source file to values in a target file. The comparison can be based on one or more field values. DB_INFILE returns the value 1 (TRUE) if the set of source fields matches a set of values from the target file. Otherwise, the function returns 0 (zero, FALSE). DB_INFILE can be used where a function is valid in a FOCUS request, such as in a DEFINE or a WHERE phrase.

The target file can be any data source that FOCUS can read. Depending on the data sources accessed and the components in the request, either FOCUS or an RDBMS will process the comparison of values.

If FOCUS processes the comparison, it reads the target data source and dynamically creates a sequential file containing the target data values, along with a synonym describing the data file. It then builds IF or WHERE structures in memory with all combinations of source and target values. If the target data contains characters that FOCUS considers wildcard characters, it will treat them as wildcard characters unless the command SET EQTEST = EXACT is in effect.

The following situations exist when a relational data source is the source file:

- **The target values are in a relational data source from the same RDBMS and connection.**
  In this case, the target file referenced by DB_INFILE can be:

  - An SQL file containing a subquery that retrieves the target values. A synonym must exist that describes the target SQL file. The Access File must specify the CONNECTION and DATASET for the target file.
If the subquery results in a SELECT statement supported by the RDBMS, the relational adapter inserts the subquery into the WHERE predicate of the generated SQL.

If the subquery does not result in a valid SELECT statement for the RDBMS, the relational adapter retrieves the target values. It then generates a WHERE predicate, with a list of all combinations of source and target field values.

You can create an SQL file containing a subquery and a corresponding synonym using the HOLD FORMAT SQL_SCRIPT command.

- A relational data source. A synonym must exist that describes the target data source.

  If the data source contains only those fields referenced by DB_INFILE as target fields, the relational adapter creates a subquery that retrieves the target values. If the subquery results in a SELECT statement supported by the RDBMS, the relational adapter inserts the subquery into the WHERE predicate of the generated SQL.

  If the subquery does not result in a valid SELECT statement for the RDBMS, the relational adapter retrieves a unique list of the target values. It then generates a WHERE predicate with a list of all combinations of source and target field values.

- The target values are in a non-relational data source or a relational data source from a different RDBMS or connection. In this case, the target values are retrieved and passed to FOCUS for processing.

**Syntax:**

**How to Compare Source and Target Field Values With DB_INFILE**

```
DB_INFILE(target_file, s1, t1, ... sn, tn)
```

where:

target_file

  Is the synonym for the target file.

s1, ..., sn

  Are fields from the source file.

t1, ..., tn

  Are fields from the target file.

The function returns the value 1 if a set of target values matches the set of source values. Otherwise, the function returns a zero (0).
Reference: Usage Notes for DB_INFILE

- If both the source and target data sources have MISSING=ON for a comparison field, then a missing value in both files is considered an equality. If MISSING=OFF in one or both files, a missing value in one or both files results in an inequality.

- Values are not padded or truncated when compared, except when comparing date and date-time values.
  - If the source field is a date field and the target field is a date-time field, the time component is removed before comparison.
  - If the source field is a date-time field and the target field is a date field, a zero time component is added to the target value before comparison.

- If an alphanumeric field is compared to a numeric field, an attempt will be made to convert the alphanumeric value to a number before comparison.

- If FOCUS processes the comparison, and the target data contains characters that FOCUS considers wildcard characters, it will treat them as wildcard characters unless the command SET EQTEST = EXACT is in effect.

Example: Comparing Source and Target Values Using an SQL Subquery File

This example uses the WF_RETAIL DB2 data source.

The SQL file named retail_subquery.sql contains the following subquery that retrieves specified state codes in the Central and NorthEast regions:

```sql
SELECT MAX(T11.REGION), MAX(T11.STATECODE) FROM wrd_dim_geography T11
WHERE (T11.STATECODE IN('AR', 'IA', 'KS', 'KY', 'WY', 'CT', 'MA', 'NJ', 'NY', 'RI')) AND (T11.REGION IN('Central', 'NorthEast')) GROUP BY T11.REGION, T11.STATECODE
```

The retail_subquery.mas Master File follows:

```plaintext
FILENAME=RETAIL_SUBQUERY, SUFFIX=DB2, 
SEGMENT=RETAIL_SUBQUERY, SEGTYPE=S0, 
FIELDNAME=REGION, ALIAS=E01, USAGE=A15V, ACTUAL=A15V, MISSING=ON, 
FIELDNAME=STATECODE, ALIAS=E02, USAGE=A2, ACTUAL=A2, MISSING=ON, 
```

The retail_subquery.acx Access File follows:

```plaintext
SEGNAME=RETAIL_SUBQUERY, CONNECTION=CON1, DATASET=RETAIL_SUBQUERY.SQL, 
```
The following request uses the DB_INFILE function to compare region names and state codes against the names retrieved by the subquery:

```
TABLE FILE WF
SUM REVENUE
BY REGION
BY STATECODE
WHERE DB_INFILE(RETAIL_SUBQUERY, REGION, REGION, STATECODE, STATECODE)
ON TABLE SET PAGE NOPAGE
END
```

The trace shows that the subquery was inserted into the WHERE predicate in the generated SQL:

```
SELECT
  T11."REGION",
  T11."STATECODE",
  SUM(T1."Revenue")
FROM
  wrd_fact_sales T1,
  wrd_dim_customer T5,
  wrd_dim_geography T11
WHERE
  (T5."ID_CUSTOMER" = T1."ID_CUSTOMER") AND
  (T11."ID_GEOGRAPHY" = T5."ID_GEOGRAPHY") AND
  ((T11."REGION", T11."STATECODE") IN (SELECT MAX(T11.REGION),
    MAX(T11.STATECODE) FROM wrd_dim_geography T11 WHERE
    (T11.STATECOD In('AR', 'IA', 'KS', 'KY', 'WY', 'CT', 'MA',
    'NJ', 'NY', 'RI')) AND (T11.REGION IN('Central', 'NorthEast'))
  GROUP BY T11.REGION, T11.STATECODE))
GROUP BY
  T11."REGION",
  T11."STATECODE"
ORDER BY
  T11."REGION",
  T11."STATECODE"
FOR FETCH ONLY;
END
```

**Example:** Comparing Source and Target Values Using a Sequential File

The empvalues.ftm sequential file contains the last and first names of employees in the MIS department:

```
SMITH         MARY         JONES        DIANE       MCCOY
JOHN          BLACKWOOD    ROSEMARIE    GREENSPAN  MARY
CROSS         BARBARA
```
The empvalues.mas Master File describes the data in the empvalues.ftm file

FILENAME=EMPVALUES, SUFFIX=FIX, IOTYPE=BINARY, $
SEGMENT=EMPVALUE, SEGTYPE=S0, $
FIELDNAME=LN, ALIAS=E01, USAGE=A15, ACTUAL=A16, $
FIELDNAME=FN, ALIAS=E02, USAGE=A10, ACTUAL=A12, $

**Note:** You can create a sequential file, along with a corresponding synonym, using the HOLD FORMAT SQL_SCRIPT command.

The following request against the FOCUS EMPLOYEE data source uses the DB_INFILE function to compare employee names against the names stored in the empvalues.ftm file:

FILEDEF EMPVALUES DISK baseapp/empvalues.ftm
TABLE FILE EMPLOYEE
SUM CURR_SAL
BY LAST_NAME BY FIRST_NAME
WHERE DB_INFILE(EMPVALUES, LAST_NAME, LN, FIRST_NAME, FN)
ON TABLE SET PAGE NOPAGE
END

The output is:

<table>
<thead>
<tr>
<th>LAST_NAME</th>
<th>FIRST_NAME</th>
<th>CURR_SAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLACKWOOD</td>
<td>ROSEMARIE</td>
<td>$21,780.00</td>
</tr>
<tr>
<td>CROSS</td>
<td>BARBARA</td>
<td>$27,062.00</td>

</table>

**Syntax:** How to Control DB_INFILE Optimization

To control whether to prevent optimization of the DB_INFILE expression, issue the following command:

```
SET DB_INFILE = {DEFAULT|EXPAND_ALWAYS|EXPAND_NEVER}
```

In a TABLE request, issue the following command:

```
ON TABLE SET DB_INFILE  {DEFAULT|EXPAND_ALWAYS|EXPAND_NEVER}
```
DB_LOOKUP: Retrieving Data Source Values

where:

**DEFAULT**

Enables DB_INFILE to create a subquery if its analysis determines that it is possible. This is the default value.

**EXPAND_ALWAYS**

Prevents DB_INFILE from creating a subquery. Instead, it expands the expression into IF and WHERE clauses in memory.

**EXPAND_NEVER**

Prevents DB_INFILE from expanding the expression into IF and WHERE clauses in memory. Instead, it attempts to create a subquery. If this is not possible, a FOC32585 message is generated and processing halts.

**DB_LOOKUP: Retrieving Data Source Values**

You can use the DB_LOOKUP function to retrieve a value from one data source when running a request against another data source, without joining or combining the two data sources.

DB_LOOKUP compares pairs of fields from the source and lookup data sources to locate matching records and retrieve the value to return to the request. You can specify as many pairs as needed to get to the lookup record that has the value you want to retrieve. If your field list pairs do not lead to a unique lookup record, the first matching lookup record retrieved is used.

DB_LOOKUP can be called in a DEFINE command, TABLE COMPUTE command, MODIFY COMPUTE command, or DataMigrator flow.

There are no restrictions on the source file. The lookup file can be any non-FOCUS data source that is supported as the cross referenced file in a cluster join. The lookup fields used to find the matching record are subject to the rules regarding cross-referenced join fields for the lookup data source. A fixed format sequential file can be the lookup file if it is sorted in the same order as the source file.

**Syntax:**

**How to Retrieve a Value From a Lookup Data Source**

DB_LOOKUP(look_mf, srcfld1, lookfld1, srcfld2, lookfld2, ..., returnfld);

where:

**look_mf**

Is the lookup Master File.
srcfld1, srcfld2 ...

Are fields from the source file used to locate a matching record in the lookup file.

lookfld1, lookfld2 ...

Are columns from the lookup file that share values with the source fields. Only columns in
the table or file can be used; columns created with DEFINE cannot be used. For multi-
segment synonyms, only columns in the top segment can be used.

returnfld

Is the name of a column in the lookup file whose value is returned from the matching
lookup record. Only columns in the table or file can be used; columns created with DEFINE
cannot be used.

Reference: Usage Notes for DB_LOOKUP

- The maximum number of pairs that can be used to match records is 63.

- If the lookup file is a fixed format sequential file, it must be sorted and retrieved in the
  same order as the source file, unless the ENGINE INT SET CACHE=ON command is in
  effect. Having this setting in effect may also improve performance if the values will be
  looked up more than once. The key field of the sequential file must be the first lookup field
  specified in the DB_LOOKUP request. If it is not, no records will match.

In addition, if a DB_LOOKUP request against a sequential file is issued in a DEFINE FILE
command, you must clear the DEFINE FILE command at the end of the TABLE request that
references it, or the lookup file will remain open. It will not be reusable until closed and
may cause problems when you exit. Other types of lookup files can be reused without
clearing the DEFINE. They will be cleared automatically when all DEFINE fields are cleared.

- If the lookup field has the MISSING=ON attribute in its Master File and the DEFINE or
  COMPUTE command specifies MISSING ON, the missing value is returned when the lookup
  field is missing. Without MISSING ON in both places, the missing value is converted to a
default value (blank for an alphanumeric field, zero for a numeric field).

- Source records display on the report output even if they lack a matching record in the
  lookup file.

- Only real fields in the lookup Master File are valid as lookup and return fields.

- If there are multiple rows in the lookup table where the source field is equal to the lookup
  field, the first value of the return field is returned.
**Example:** Retrieving a Value From a LOOKUP Table

DB_LOOKUP takes the value for STORE_CODE and retrieves the STORENAME associated with it.

\[
\text{DB_LOOKUP}(\text{dmcomp,STORE_CODE,STORE_CODE,STORENAME})
\]

For 1003CA the result is Audio Expert.

For 1004MD the result is City Video For 2010AZ the result is eMart.

**DECODE: Decoding Values**

The DECODE function assigns values based on the coded value of an input field. DECODE is useful for giving a more meaningful value to a coded value in a field. For example, the field GENDER may have the code F for female employees and M for male employees for efficient storage (for example, one character instead of six for female). DECODE expands (decodes) these values to ensure correct interpretation on a report.

You can use DECODE by supplying values directly in the function or by reading values from a separate file.

**Syntax:** How to Supply Values in the Function

\[
\text{DECODE } \text{fieldname}(\text{code1 result1 code2 result2} \ldots [\text{ELSE default }]);
\]

\[
\text{DECODE } \text{fieldname}(\text{filename} \ldots [\text{ELSE default}]);
\]

where:

- **fieldname**
  - Alphanumeric or Numeric
  - Is the name of the input field.

- **code**
  - Alphanumeric or Numeric
  - Is the coded value that DECODE compares with the current value of *fieldname*. If the value has embedded blanks, commas, or other special characters, it must be enclosed in single quotation marks. When DECODE finds the specified value, it returns the corresponding result. When the code is compared to the value of the field name, the code and field name must be in the same format.
result
Alphanumeric or Numeric

Is the returned value that corresponds to the code. If the result has embedded blanks or
commas, or contains a negative number, it must be enclosed in single quotation marks.
Do not use double quotation marks (").

If the result is presented in alphanumeric format, it must be a non-null, non-blank string.
The format of the result must correspond to the data type of the expression.

default
Alphanumeric or Numeric

Is the value returned as a result for non-matching codes. The format must be the same as
the format of result. If you omit a default value, DECODE assigns a blank or zero to non-
matching codes.

filename
Alphanumeric

Is the name of the file in which code/result pairs are stored. Every record in the file must
contain a pair.

You can use up to 40 lines to define the code and result pairs for any given DECODE function,
or 39 lines if you also use an ELSE phrase. Use either a comma or blank to separate the code
from the result, or one pair from another.

Note: DECODE has no output argument.

Example: Supplying Values Using the DECODE Function

DECODE returns the state abbreviation for PLANT.

DECODE PLANT(BOS 'MA' DAL 'TX' LA 'CA')

For BOS, the result is MA.
For DAL, the result is TX.
For LA, the result is CA.

FIND: Verifying the Existence of a Value in a Data Source

The FIND function determines if an incoming data value is in an indexed FOCUS data source
field. The function sets a temporary field to a non-zero value if the incoming value is in the data
source field, and to 0 if it is not. A value greater than zero confirms the presence of the data
value, not the number of instances in the data source field.
You can also use FIND in a VALIDATE command to determine if a transaction field value exists in another FOCUS data source. If the field value is not in that data source, the function returns a value of 0, causing the validation test to fail and the request to reject the transaction.

You can use any number of FINDs in a COMPUTE or VALIDATE command. However, more FINDs increase processing time and require more buffer space in memory.

**Limit:** FIND does not work on files with different DBA passwords.

The opposite of FIND is NOT FIND. The NOT FIND function sets a temporary field to 1 if the incoming value is not in the data source and to 0 if the incoming value is in the data source.

**Syntax:**

How to Verify the Existence of a Value in a Data Source

```plaintext
FIND(fieldname [AS dbfield] IN file);
```

where:

- **fieldname**
  Is the name of the field that contains the incoming data value.

- **AS dbfield**
  Is the name of the data source field whose values are compared to the incoming field values.

  This field must be indexed. If the incoming field and the data source field have the same name, omit this phrase.

- **file**
  Is the name of the indexed FOCUS data source.

**Note:**

- FIND does not use an output argument.
- Do not include a space between FIND and the left parenthesis.

**Example:** Verifying the Existence of a Value in an Indexed Field

FIND determines if a supplied value in EMP_ID is in the EDUCFILE data source.

```plaintext
FIND(EMP_ID IN EDUCFILE)
```
**IMPUTE: Replacing Missing Values With Aggregated Values**

IMPUTE calculates a value to replace missing numeric data on report output, within a partition.

In place of eliminating data records with missing values from analysis, IMPUTE enables you to substitute a variety of estimates for the missing values, including the mean, the median, the mode, or a numeric constant, all calculated within the data partition specified by the reset key. This function is designed to be used with detail level reports (PRINT or LIST commands), and with calculated values (fields created with the COMPUTE command).

**Syntax:**

How to Replace Missing Values With Aggregated Values

`IMPUTE(field, reset_key, replacement)`

where:

*field*

Is the name of the numeric input field that is defined with MISSING ON.

*reset_key*

Defines the partition for the calculation. Valid values are:

- A sort field name.
- PRESET, which uses the break defined by the SET PARTITION_ON command.
- TABLE, which performs the calculation on the entire table.

*replacement*

Is a numeric constant or one of the following:

- MEAN
- MEDIAN
- MODE
Example: Replacing Missing Values With Aggregated Values

To run this example, the FOCUS data source SALEMISS must be created. SALEMISS is the SALES data source with some missing values added in the RETURNS and DAMAGED fields. The following is the SALEMISS Master File, which should be added to the IBISAMP application.

FILENAME=KSALES, SUFFIX=FOC, REMARKS="Legacy Metadata Sample: sales";

SEGNAME=STOR_SEG, SECTYPE=S1,
FIELDNAME=STORE_CODE, ALIAS=SNO, FORMAT=A3,
FIELDNAME=CITY, ALIAS=CTY, FORMAT=A15,
FIELDNAME=AREA, ALIAS=LOC, FORMAT=A1,

SEGNAME=DATE_SEG, PARENT=STOR_SEG, SECTYPE=SH1,
FIELDNAME=DATE, ALIAS=DTE, FORMAT=A4MD,

SEGNAME=PRODUCT, PARENT=DATE_SEG, SECTYPE=S1,
FIELDNAME=PROD_CODE, ALIAS=PCODE, FORMAT=A3, FIELDTYPE=I,
FIELDNAME=UNIT_SOLD, ALIAS=SOLD, FORMAT=I5,
FIELDNAME=RETAIL_PRICE, ALIAS=RP, FORMAT=D5.2M,
FIELDNAME=DELIVER_AMT, ALIAS=SHIP, FORMAT=I5,
FIELDNAME=OPENING_AMT, ALIAS=INV, FORMAT=I5,
FIELDNAME=RETURNS, ALIAS=RTN, FORMAT=I3, MISSING=ON,
FIELDNAME=DAMAGED, ALIAS=BAD, FORMAT=I3, MISSING=ON,
The following procedure creates the SALEMISS data source and then adds the missing values to the RETURNS and DAMAGED fields:

```
CREATE FILE ibisamp/SALEMISS
MODIFY FILE ibisamp/SALEMISS
FIXFORM STORE_CODE/3 CITY/15 AREA/1 DATE/4 PROD_CODE/3
FIXFORM UNIT_SOLD/5 RETAIL_PRICE/5 DELIVER_AMT/5
FIXFORM OPENING_AMT/5 RETURNS/3 DAMAGED/3

K1 NEWARK        U1018B10  13 .99   30   15  1  1
END
-RUN
```
The following request against the SALEMISS data source generates replacement values for the missing values in the RETURNS field, using only the values within the same store.

SET PARTITION_ON=FIRST
TABLE FILE SALEMISS
PRINT RETURNS
COMPUTE MEDIAN1 = IMPUTE(RETURNS, PRESET, MEDIAN);
COMPUTE MEAN1 = IMPUTE(RETURNS, PRESET, MEAN);
COMPUTE MODE1 = IMPUTE(RETURNS, PRESET, MODE);
BY STORE_CODE
ON TABLE SET PAGE NOPAGE
ON TABLE SET STYLE *
TYPE=REPORT, GRID=OFF,$
ENDSTYLE
END
The output is shown in the following image. The missing values occur in store 14Z, and the replacement values are calculated using only the RETURNS values from that store because PARTITION_ON is set to FIRST.

<table>
<thead>
<tr>

</table>

LAST: Retrieving the Preceding Value

The LAST function retrieves the preceding value for a field.

The effect of LAST depends on whether it appears in an extract or load transformation:

- In an extract transformation the LAST value applies to the previous record retrieved from the data source before sorting takes place.
In a load transformation, the LAST value applies to the record in the previous record loaded.

**Syntax:**

**How to Retrieve the Preceding Value**

`LAST fieldname`

where:

`fieldname`

Alphanumeric or Numeric

Is the field name.

**Note:** LAST does not use an output argument.

**Example:**

**Retrieving the Preceding Value**

LAST retrieves the previous value of DEPARTMENT:

`LAST DEPARTMENT`

**LOOKUP: Retrieving a Value From a Cross-referenced Data Source**

The LOOKUP function retrieves a data value from a cross-referenced FOCUS data source in a MODIFY request. You can retrieve data from a data source cross-referenced statically in a synonym or a data source joined dynamically to another by the JOIN command. LOOKUP retrieves a value, but does not activate the field. LOOKUP is required because a MODIFY request, unlike a TABLE request, cannot read cross-referenced data sources freely.

LOOKUP allows a request to use the retrieved data in a computation or message, but it does not allow you to modify a cross-referenced data source.

LOOKUP can read a cross-referenced segment that is linked directly to a segment in the host data source (the host segment). This means that the cross-referenced segment must have a segment type of KU, KM, DKU, or DKM (but not KL or KLU) or must contain the cross-referenced field specified by the JOIN command. Because LOOKUP retrieves a single cross-referenced value, it is best used with unique cross-referenced segments.

The cross-referenced segment contains two fields used by LOOKUP:

- The field containing the retrieved value. Alternatively, you can retrieve all the fields in a segment at one time. The field, or your decision to retrieve all the fields, is specified in LOOKUP.

For example, LOOKUP retrieves all the fields from the segment
RTN = LOOKUP(SEG.DATE_ATTEND);

- The cross-referenced field. This field shares values with a field in the host segment called the host field. These two fields link the host segment to the cross-referenced segment. LOOKUP uses the cross-referenced field, which is indexed, to locate a specific segment instance.

When using LOOKUP, the MODIFY request reads a transaction value for the host field. It then searches the cross-referenced segment for an instance containing this value in the cross-referenced field:

- If there are no instances of the value, the function sets a return variable to 0. If you use the field specified by LOOKUP in the request, the field assumes a value of blank if alphanumeric and 0 if numeric.

- If there are instances of the value, the function sets the return variable to 1 and retrieves the value of the specified field from the first instance it finds. There can be more than one if the cross-referenced segment type is KM or DKM, or if you specified the ALL keyword in the JOIN command.

**Syntax:**

**How to Retrieve a Value From a Cross-referenced Data Source**

`LOOKUP(field);`

where:

`field`

- Is the name of the field to retrieve in the cross-referenced file. If the field name also exists in the host data source, you must qualify it here. Do not include a space between LOOKUP and the left parenthesis.

**Note:** LOOKUP does not use an *output* argument.

**Example:**

**Using the LOOKUP Function**

LOOKUP finds the enrollment date from DATE_ENROLL. The result can then be used to validate an expression.

`LOOKUP(DATE_ENROLL)`
NULLIF: Returning a Null Value When Parameters Are Equal

NULLIF returns a null (missing) value when its parameters are equal. If they are not equal, it returns the first value. The field to which the value is returned should have MISSING ON.

Syntax: How to Return a Null Value for Equal Parameters

```
NULLIF(arg1, arg2)
```

where:

- `arg1, arg2`
  - Any type of field, constant, or expression.
  - Are the input parameters that are tested for equality. They must either both be numeric or both be alphanumeric.

The output data type is the same as the input data types.

Example: Testing for Equal Parameters

NULLIF tests the DAMAGED and RETURNS field values for equality.

```
NULLIF(DAMAGED, RETURNS)
```

For DAMAGED=3 and RETURNS = 3, the result is MISSING (.).
For DAMAGED=2 and RETURNS = 3, the result is 2.
Simplified date and date-time functions have streamlined parameter lists, similar to those used by SQL functions. In some cases, these simplified functions provide slightly different functionality than previous versions of similar functions.

The simplified functions do not have an output argument. Each function returns a value that has a specific data type.

When used in a request against a relational data source, these functions are optimized (passed to the RDBMS for processing).

Standard date and date-time formats refer to YYMD and HYYMD syntax (dates that are not stored in alphanumeric or numeric fields). Dates not in these formats must be converted before they can be used in the simplified functions. Input date and date-time parameters must provide full component dates. Literal date-time values can be used with the DT function.

All arguments can be either literals, field names, or amper variables.

**In this chapter:**

- **DT_CURRENT_DATE:** Returning the Current Date
- **DT_CURRENT_DATETIME:** Returning the Current Date and Time
- **DT_CURRENT_TIME:** Returning the Current Time
- **DTADD:** Incrementing a Date or Date-Time Component
- **DTDIFF:** Returning the Number of Component Boundaries Between Date or Date-Time Values
- **DTIME:** Extracting Time Components From a Date-Time Value
- **DTPART:** Returning a Date or Date-Time Component in Integer Format
- **DTRUNC:** Returning the Start of a Date Period for a Given Date
DT_CURRENT_DATE: Returning the Current Date

The DT_CURRENT_DATE function returns the current date-time provided by the running operating environment in date-time format. The time portion of the date-time is set to zero.

Syntax:

How to Return the Current Date

DT_CURRENT_DATE()

Example:

Returning the Current Date

DT_CURRENT_DATE returns the current date.

DT_CURRENT_DATE()

For September 8, 2016 (returning to a YYMD field), the result is 2016/09/08.

DT_CURRENT_DATETIME: Returning the Current Date and Time

DT_CURRENT_DATETIME returns the current date and time provided by the running operating environment in date-time format, with a specified time precision.

Syntax:

How to Return the Current Date and Time

DT_CURRENT_DATETIME(component)

where:

component

Is one of the following time precisions.

- SECOND.
- MILLISECOND.
- MICROSECOND.

Note: The field to which the value is returned must have a format that supports the time precision requested.

Example:

Returning the Current Date and Time

DT_CURRENT_DATETIME returns the current date and time to microsecond precision.

DT_CURRENT_DATETIME(MICROSECOND)
For September 8, 2016 at 5:10:31.605718 p.m. (returned to a field with format HYYMDm), the result is 2016/09/08 17:10:31.605718.

**DT_CURRENT_TIME: Returning the Current Time**

The DT_CURRENT_TIME function returns the current time provided by the running operating environment in date-time format, with a specified time precision. The date portion of the returned date-time value is set to zero.

**Syntax:**

```
DT_CURRENT_TIME(component)
```

where:

- **component**
  - Is one of the following time precisions.
    - **SECOND.**
    - **MILLISECOND.**
    - **MICROSECOND.**

**Note:** The field to which the value is returned must have a format that supports the time precision requested.

**Example:**

**Returning the Current Time**

DT_CURRENT_TIME returns the current time in milliseconds.

```
DT_CURRENT_TIME (MILLISECOND)
```

For 5:23:13.098 p.m. (returned to a field with format HHISs), the result is 17:23:13.098.

**DTADD: Incrementing a Date or Date-Time Component**

Given a date in standard date or date-time format, DTADD returns a new date after adding the specified number of a supported component. The returned date format is the same as the input date format.

**Syntax:**

```
DTADD(date, component, increment)
```
where:

\textit{date}

Date or date-time

Is the date or date-time value to be incremented, which must provide a full component date.

\textit{component}

Keyword

Is the component to be incremented. Valid components (and acceptable values) are:

- YEAR (1-9999).
- QUARTER (1-4).
- MONTH (1-12).
- WEEK (1-53). This is affected by the WEEKFIRST setting.
- DAY (of the Month, 1-31).
- HOUR (0-23).
- MINUTE (0-59).
- SECOND (0-59).

\textit{increment}

Integer

Is the value (positive or negative) to add to the component.

\textbf{Example: Incrementing the DAY Component of a Date}

DTADD adds three days to the employee date of birth:

\[
\text{DTADD}\left(\text{DATE\_OF\_BIRTH, DAY, 3}\right)
\]

For 1976/10/21, the result is 1976/10/24.

\textbf{Reference: Usage Notes for DTADD}

- Each element must be manipulated separately. Therefore, if you want to add 1 year and 1 day to a date, you need to call the function twice, once for YEAR (you need to take care of leap years) and once for DAY. The simplified functions can be nested in a single expression, or created and applied in separate DEFINE or COMPUTE expressions.
With respect to parameter validation, DTADD will not allow anything but a standard date or a date-time value to be used in the first parameter.

The increment is not checked, and the user should be aware that decimal numbers are not supported and will be truncated. Any combination of values that increases the YEAR beyond 9999 returns the input date as the value, with no message. If the user receives the input date when expecting something else, it is possible there was an error.

**DTDIFF: Returning the Number of Component Boundaries Between Date or Date-Time Values**

Given two dates in standard date or date-time formats, DTIFF returns the number of given component boundaries between the two dates. The returned value has integer format for calendar components or double precision floating point format for time components.

**Syntax:**

How to Return the Number of Component Boundaries

```
DTDIFF(end_date, start_date, component)
```

where:

**end_date**

Date or date-time

Is the ending full-component date in either standard date or date-time format. If this date is given in standard date format, all time components are assumed to be zero.

**start_date**

Date or date-time

Is the starting full-component date in either standard date or date-time format. If this date is given in standard date format, all time components are assumed to be zero.

**component**

Keyword

Is the component on which the number of boundaries is to be calculated. For example, QUARTER finds the difference in quarters between two dates. Valid components (and acceptable values) are:

- YEAR (1-9999).
- QUARTER (1-4).
- MONTH (1-12).
WEEK (1-53). This is affected by the WEEKFIRST setting.

DAY (of the Month, 1-31).

HOUR (0-23).

MINUTE (0-59).

SECOND (0-59).

**Example:** Returning the Number of Years Between Two Dates

DTDIFF calculates employee age when hired:

```
DTDIFF(START_DATE, DATE_OF_BIRTH, YEAR)
```

For the date of birth 1991/06/04 and the start date 2008/11/14, the result is 17.

DTDIFF calculates the difference between two date-time values in minutes:

```
DTDIFF(DATETIME1, DATETIME2, MINUTES)
```

For DATETIME1 = 2020/01/16 12:25 and DATETIME2 = 2020/01/16 12:20, the result is 5.

For DATETIME1 = 2020/01/16 12:25 and DATETIME2 = 2020/01/15 12:20, the result is 1445.

**DTIME: Extracting Time Components From a Date-Time Value**

Given a date-time value and time component keyword as input, DTIME returns the value of all of the time components up to and including the requested component. The remaining time components in the value are set to zero. The field to which the time component is returned must have a time format that supports the component being returned.

**Syntax:** How to Extract a Time Component From a Date-Time Value

```
DTIME(datetime, component)
```

where:

```
datetime
```

Date-time

Is the date-time value from which to extract the time component. It can be a field name or a date-time literal. It must provide a full component date.
component

Keyword

Valid values are:

- TIME. The complete time portion is returned. Its smallest component depends on the input date-time format. Nanoseconds are not supported or returned.
- HOUR. The time component up to and including the hour component is extracted.
- MINUTE. The time component up to and including the minute component is extracted.
- SECOND. The time component up to and including the second component is extracted.
- MILLISECOND. The time component up to and including the millisecond component is extracted.
- MICROSECOND. The time component up to and including the microsecond component is extracted.

Example: Extracting Time Components

DTIME extracts the TIME component from the data-time value 2018/01/17 05:45:22.777888.

\[
\text{DTIME(DT(2018/01/17 05:45:22.777888), TIME)}
\]

The result is 05:45:22.777888.

DTPART: Returning a Date or Date-Time Component in Integer Format

Given a date in standard date or date-time format and a component, DTPART returns the component value in integer format.

Syntax: How to Return a Date or Date-Time Component in Integer Format

\[
\text{DTPART(date, component)}
\]

where:

- \text{date}
  - Date or date-time
    - Is the full-component date in standard date or date-time format.
DTRUNC: Returning the Start of a Date Period for a Given Date

Component Keyword
Is the component to extract in integer format. Valid components (and values) are:

- YEAR (1-9999).
- QUARTER (1-4).
- MONTH (1-12).
- WEEK (of the year, 1-53). This is affected by the WEEKFIRST setting.
- DAY (of the Month, 1-31).
- DAY_OF_YEAR (1-366).
- WEEKDAY (day of the week, 1-7). This is affected by the WEEKFIRST setting.
- HOUR (0-23).
- MINUTE (0-59).
- SECOND (0-59).
- MILLISECOND (0-999).
- MICROSECOND (0-999999).

Example: Extracting the Quarter Component as an Integer
DTPART extracts the quarter from the employee start date:

\[
\text{DTPART(START\_DATE, QUARTER)}
\]

For 2009/04/11, the result is 2.

DTRUNC: Returning the Start of a Date Period for a Given Date
Given a date or timestamp and a component, DTRUNC returns the first date within the period specified by that component.

Syntax: How to Return the First or Last Date of a Date Period

\[
\text{DTRUNC(date\_or\_timestamp, date\_period)}
\]
where:

\textit{date\_or\_timestamp}

Date or date-time

Is the date or timestamp of interest, which must provide a full component date.

\textit{date\_period}

Is the period whose starting or ending date you want to find. Can be one of the following:

- \textbf{DAY}, returns the date that represents the input date (truncates the time portion, if there is one).
- \textbf{YEAR}, returns the date of the first day of the year.
- \textbf{MONTH}, returns the date of the first day of the month.
- \textbf{QUARTER}, returns the date of the first day in the quarter.
- \textbf{WEEK}, returns the date that represents the first date of the given week.

By default, the first day of the week will be Sunday, but this can be changed using the \textbf{WEEKFIRST} parameter.

- \textbf{YEAR\_END}, returns the last date of the year.
- \textbf{QUARTER\_END}, returns the last date of the quarter.
- \textbf{MONTH\_END}, returns the last date of the month.
- \textbf{WEEK\_END}, returns the last date of the week.

\textbf{Example: Returning the First Date in a Date Period}

DTRUNC returns the first date of the quarter given the date of birth:

\texttt{DTRUNC(DATE\_OF\_BIRTH,QUARTER)}

For 1993/03/27, the result is 1993/03/01.

\textbf{Example: Using the Start of Week Parameter for DTRUNC}

DTRUNC returns the date that represents the start of the week.

\texttt{DTRUNC(START\_DATE, WEEK)}

For 2013/01/15, the result is 2013/01/13.
**Example:** Returning the Date of the Last Day of a Week

DTRUNC calculates the date of the end of the week.

\[
\text{WEEKEND/YYMD} = \text{DTRUNC(START\_DATE, WEEK\_END)}
\]

For 2013/01/15, the result is 2013/01/19.
Date Functions

Date functions manipulate date values. There are two types of date functions:

- Standard date functions for use with non-legacy dates.
- Legacy date functions for use with legacy dates.

If a date is in an alphanumeric or numeric field that contains date display options (for example, I6YMD), you must use the legacy date functions.

In this chapter:

- Overview of Date Functions
- Using Standard Date Functions
- DATEADD: Adding or Subtracting a Date Unit to or From a Date
- DATECVT: Converting the Format of a Date
- DATEDIF: Finding the Difference Between Two Dates
- DATEMOV: Moving a Date to a Significant Point
- DATETRAN: Formatting Dates in International Formats
- FIYR: Obtaining the Financial Year
- FIQTR: Obtaining the Financial Quarter
- FIYYQ: Converting a Calendar Date to a Financial Date
- TODAY: Returning the Current Date
- Using Legacy Date Functions
- AYMD: Adding or Subtracting Days
- CHGDAT: Changing How a Date String Displays
- DA Functions: Converting a Legacy Date to an Integer
- DMY, MDY, YMD: Calculating the Difference Between Two Dates
- DOWK and DOWKL: Finding the Day of the Week
- DT Functions: Converting an Integer to a Date
- GREGDT: Converting From Julian to Gregorian Format
- JULDAT: Converting From Gregorian to Julian Format
- YM: Calculating Elapsed Months
Overview of Date Functions

The following explains the difference between the types of date functions:

- **Standard date** functions are for use with standard date formats, or just date formats. A date format refers to internally stored data that is capable of holding date components, such as century, year, quarter, month, and day. It does not include time components. A synonym does not specify an internal data type or length for a date format. Instead, it specifies display date components, such as D (day), M (month), Q (quarter), Y (2-digit year), or YY (4-digit year). For example, format MDYY is a date format that has three date components; it can be used in the USAGE attribute of a synonym. A real date value, such as March 9, 2004, described by this format is displayed as 03/09/2004, by default. Date formats can be full component and non-full component. Full component formats include all three letters, for example, D, M, and Y. JUL for Julian can also be included. All other date formats are non-full component. Some date functions require full component arguments for date fields, while others will accept full or non-full components. A date format was formerly called a smart date.

- **Legacy date** functions are for use with legacy dates only. A legacy date refers to formats with date edit options, such as I6YMD, A6MDY, I8YYMD, or A8MDYY. For example, A6MDY is a 6-byte alphanumeric string. The suffix MDY indicates the order in which the date components are stored in the field, and the prefix I or A indicates a numeric or alphanumeric form of representation. For example, a value '030599' can be assigned to a field with format A6MDY, which will be displayed as 03/05/99.

Date formats have an internal representation matching either numeric or alphanumeric format. For example, A6MDY matches alphanumeric format, YYMD and I6DMY match numeric format. When function output is a date in specified by output, it can be used either for assignment to another date field of this format, or it can be used for further data manipulation in the expression with data of matching formats. Assignment to another field of a different date format, will yield a random result.

All but three date functions deal with only one date format. The exceptions are DATECVT, HCNVRT, and HDATE, which convert one date type into another.

Using Standard Date Functions

When using standard date functions, you need to understand the settings that alter the behavior of these functions, as well as the acceptable formats and how to supply values in these formats.
You can affect the behavior of date functions in the following ways:

- Defining which days of the week are work days and which are not. Then, when you use a date function involving work days, dates that are not work days are ignored. For details, see Specifying Work Days on page 197.

- Determining whether to display leading zeros when a date function in Dialogue Manager returns a date. For details, see Enabling Leading Zeros For Date and Time Functions in Dialogue Manager on page 202.

For detailed information on each standard date function, see:

- DATEADD: Adding or Subtracting a Date Unit to or From a Date on page 203
- DATECVT: Converting the Format of a Date on page 205
- DATEDIF: Finding the Difference Between Two Dates on page 207
- DATEMOV: Moving a Date to a Significant Point on page 209
- DATETRAN: Formatting Dates in International Formats on page 214
- FIYR: Obtaining the Financial Year on page 230
- FIQTR: Obtaining the Financial Quarter on page 232
- FIYYQ: Converting a Calendar Date to a Financial Date on page 234
- TODAY: Returning the Current Date on page 235

### Specifying Work Days

You can determine which days are work days and which are not. Work days affect the DATEADD, DATEDIF, and DATEMOV functions. You identify work days as business days or holidays.

### Specifying Business Days

Business days are traditionally Monday through Friday, but not every business has this schedule. For example, if your company does business on Sunday, Tuesday, Wednesday, Friday, and Saturday, you can tailor business day units to reflect that schedule.
**Syntax:** How to Set Business Days

```plaintext
SET BUSDAYS = smtwtfs
```

where:

```plaintext
smtwtfs
```

Is the seven character list of days that represents your business week. The list has a position for each day from Sunday to Saturday:

- To identify a day of the week as a business day, enter the first letter of that day in that day's position.
- To identify a non-business day, enter an underscore (_) in that day's position.

If a letter is not in its correct position, or if you replace a letter with a character other than an underscore, you receive an error message.

**Example:** Setting Business Days to Reflect Your Work Week

The following designates work days as Sunday, Tuesday, Wednesday, Friday, and Saturday:

```plaintext
SET BUSDAYS = S_TW_FS
```

**Syntax:** How to View the Current Setting of Business Days

```plaintext
? SET BUSDAYS
```

**Specifying Holidays**

You can specify a list of dates that are designated as holidays in your company. These dates are excluded when using functions that perform calculations based on working days. For example, if Thursday in a given week is designated as a holiday, the next working day after Wednesday is Friday.

To define a list of holidays, you must:

1. Create a holiday file using a standard text editor.
2. Select the holiday file by issuing the SET command with the HDAY parameter.

**Reference:** Rules for Creating a Holiday File

- Dates must be in YYMD format.
- Dates must be in ascending order.
Each date must be on its own line.

Each year for which data exists must be included or the holiday file is considered invalid. Calling a date function with a date value outside the range of the holiday file returns a zero for business day requests.

If you are subtracting two dates in 2005, and the latest date in the holiday file is 20041231, the subtraction will not be performed. One way to avoid invalidating the holiday file is to put a date very far in the future in any holiday file you create (for example, 29991231), and then it will always be considered valid.

You may include an optional description of the holiday, separated from the date by a space.

By default, the holiday file has a file name of the form HDAYxxxx.err and is on your path, or on z/OS under PDS deployment, is a member named HDAYxxxx of a PDS allocated to DDNAME ERRORS. In your procedure or request, you must issue the SET HDAY=xxxx command to identify the file or member name. Alternatively, you can define the file to have any name and be stored anywhere or, on z/OS under PDS deployment, allocate the holiday file as a sequential file of any name or as member HDAYxxxx of any PDS. For information about using non-default holiday file names, see How to FILEDEF or DYNAM the Holiday File on page 200.

**Procedure:** How to Create a Holiday File

1. In a text editor, create a list of dates designated as holidays using the Rules for Creating a Holiday File on page 198.

2. Save the file.

If you are not using the default naming convention, see How to FILEDEF or DYNAM the Holiday File on page 200. If you are using the default naming convention, use the following instructions:

**In Windows and UNIX:** The file must be HDAYxxxx.ERR

**In z/OS:** The file must be a member of ERRORS named HDAYxxxx.

where:

*xxxx*  
Is a string of text four characters long.
Syntax: How to Select a Holiday File

SET HDAY = xxxx

where:

xxxx

Is the part of the name of the holiday file after HDAY. This string must be four characters long.

Example: Creating and Selecting a Holiday File

The following is the HDAYTEST file, which establishes holidays:

19910325 TEST HOLIDAY
19911225 CHRISTMAS

The following sets HDAYTEST as the holiday file:

SET BUSDAYS = SMTWTF
SET HDAY = TEST

Syntax: How to FILEDEF or DYNAM the Holiday File

In all environments except z/OS under PDS deployment, use the following syntax.

FILEDEF HDAYxxxx DISK (app|path)/filename.ext

where:

HDAYxxxx

Is the logical name (DDNAME) for the holiday file, where xxxx is any four characters. You establish this logical name by issuing the SET HDAY=xxxx command in your procedure or request.

app

Is the name of the application in which the holiday file resides.

path

Is the path to the holiday file.

filename.ext

Is the name of the holiday file.

On z/OS under PDS deployment, use the following to allocate a sequential holiday file.

DYNAM ALLOC {DD|FILE} HDAYxxxx DA qualif.filename.suffix SHR REU
On z/OS under PDS deployment, use the following to allocate a holiday file that is a member of a PDS.

```
DYNAM ALLOC {DD|FILE} HDAYxxxx DA qualif.filename.suffix(HDAYxxx) SHR REU
```

where:

- **HDAYxxxx**
  - Is the DDNAME for the holiday file. Your FOCEXEC or request must set the HDAY parameter to xxxx, where xxxx is any four characters you choose. If your holiday file is a member of a PDS, HDAYxxxx must also be the member name.

- **qualif.filename.suffix**
  - Is the fully-qualified name of the sequential file that contains the list of holidays or the PDS with member HDAYxxxx that contains the list of holidays.

**Example:** Defining a Holiday File

The following holiday file, named holiday.data in the c:\temp directory on Windows, defines November 3, 2011 and December 24, 2011 as holidays:

```
20111103
20111224
```

The following defines and sets the holiday file. Then DATEADD finds the next business day taking the holiday file into account:

```
FILEDEF HDAYMMMM DISK c:\ibi\holiday.data
SET HDAY = MMMM
SET BUSDAYS = _MTWTF_
DATEADD(NEWDATE, 'BD', 1);
```

For 2011/11/02, DATEADD returns 2011/11/04 because November 3 is a holiday.

**Example:** Allocating the Holiday File to a Sequential File on z/OS Under PDS Deployment

The following sequential file, named USER1.HOLIDAY.DATA, defines November 3, 2011 and December 24, 2011 as holidays:

```
20111103
20111224
```

The following defines and sets the holiday file. Then DATEADD finds the next business day taking the holiday file into account:

```
DYNAM ALLOC DD HDAYMMMM DA USER1.HOLIDAY.DATA SHR REU
SET HDAY = MMMM
DATEADD(NEWDATE, 'BD', 1);
```
For 2011/11/02, DATEADD returns 2011/11/04 because November 3 is a holiday.

**Example:** Allocating the Holiday File to a PDS Member on z/OS Under PDS Deployment

The following holiday file, member HDAYMMMM in a PDS named USER1.HOLIDAY.DATA, defines November 3, 2011 and December 24, 2011 as holidays:

```
20111103
20111224
```

The following defines and sets the holiday file. Then DATEADD finds the next business day taking the holiday file into account:

```
DYNAM ALLOC DD HDAYMMMM DA USER1.HOLIDAY.DATA(HDAYMMMM) SHR REU
SET HDAY = MMMM
SET BUSDAYS = _MTWTF_
DATEADD(NEWDATE, 'BD', 1);
```

For 2011/11/02, DATEADD returns 2011/11/04 because November 3 is a holiday.

**Enabling Leading Zeros For Date and Time Functions in Dialogue Manager**

If you use a date and time function in Dialogue Manager that returns a numeric integer format, Dialogue Manager truncates any leading zeros. For example, if a function returns the value 000101 (indicating January 1, 2000), Dialogue Manager truncates the leading zeros, producing 101, an incorrect date. To avoid this problem, use the LEADZERO parameter.

LEADZERO only supports an expression that makes a direct call to a function. An expression that has nesting or another mathematical function always truncates leading zeros. For example,

```
-SET &OUT = AYM(&IN, 1, 'I4')/100;
```

truncates leading zeros regardless of the LEADZERO parameter setting.

**Syntax:** How to Set the Display of Leading Zeros

```
SET LEADZERO = {ON|OFF}
```

where:

- **ON**
  
  Displays leading zeros if present.

- **OFF**

  Truncates leading zeros. OFF is the default value.
Example: Displaying Leading Zeros

The AYM function adds one month to the input date of December 1999:

```
-SET &IN = '9912';
-RUN
-SET &OUT = AYM(&IN, 1, 'I4');
-TYPE &OUT
```

Using the default LEADZERO setting, this yields:

```
1
```

This represents the date January 2000 incorrectly. Setting the LEADZERO parameter in the request as follows:

```
SET LEADZERO = ON
-SET &IN = '9912';
-SET &OUT = AYM(&IN, 1, 'I4');
-TYPE &OUT
```

results in the following:

```
0001
```

This correctly indicates January 2000.

DATEADD: Adding or Subtracting a Date Unit to or From a Date

The DATEADD function adds a unit to or subtracts a unit from a full component date format. A unit is one of the following:

- **Year.**
- **Month.** If the calculation using the month unit creates an invalid date, DATEADD corrects it to the last day of the month. For example, adding one month to October 31 yields November 30, not November 31, since November has 30 days.
- **Day.**
- **Weekday.** When using the weekday unit, DATEADD does not count Saturday or Sunday. For example, if you add one day to Friday, first DATEADD moves to the next weekday, Monday, then it adds a day. The result is Tuesday.
- **Business day.** When using the business day unit, DATEADD uses the BUSDAYS parameter setting and holiday file to determine which days are working days and disregards the rest. If Monday is not a working day, then one business day past Sunday is Tuesday.
Note that when the DATEADD function calculates the next or previous business day or work day, it always starts from a business day or work day. So if the actual day is Saturday or Sunday, and the request wants to calculate the next business day, the function will use Monday as the starting day, not Saturday or Sunday, and will return Tuesday as the next business day. Similarly, when calculating the previous business day, it will use the starting day Friday, and will return Thursday as the previous business day. You can use the DATEROV function to move the date to the correct type of day before using DATEADD.

DATEADD requires a date to be in date format. Since Dialogue Manager interprets a date as alphanumeric or numeric, and DATEADD requires a standard date stored as an offset from the base date, do not use DATEADD with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date.

Syntax: How to Add or Subtract a Date Unit to or From a Date

DATEADD(date, 'component', increment)

where:

date
  Date
  Is a full component date.

component
  Alphanumeric
  Is one of the following enclosed in single quotation marks:
  Y indicates a year component.
  M indicates a month component.
  D indicates a day component.
  WD indicates a weekday component.
  BD indicates a business day component.

increment
  Integer
  Is the number of date units added to or subtracted from date. If this number is not a whole unit, it is rounded down to the next largest integer.
**Note:** DATEADD does not use an output argument. It uses the format of the date argument for the result. As long as the result is a full component date, it can be assigned only to a full component date field or to integer field.

**Example:** **Adding or Subtracting a Date Unit to or From a Date**

This example finds a delivery date that is 12 business days after today:

```
DELIV_DATE/YYMD = DATEADD('&DATEMDYY', 'BD', 12);
```

It returns 20040408, which will be Thursday if today is March 23 2004, Tuesday.

To make sure it is Thursday, assign it as

```
DELIV_DAY/W = DATEADD('&DATEMDYY', 'BD', 12);
```

which returns 4, representing Thursday. Note the use of the system variable &YYMD and the natural date representation of the today's date.

**Tip:** There is an alternative way to add to or subtract from the date. As long as any standard date is internally presented as a whole number of the least significant component units (that is, a number of days for full component dates, a number of months for YYM or MY format dates, and so on), you can add/subtract the desired number of these units directly, without DATEADD. Note that you must assign the date result to the same format date field, or the same field. For example, assuming YYM_DATE is a date field of format YYM, you can add 13 months to it and assign the result to the field NEW_YYM_DT, in the following statement:

```
NEW_YYM_DT/YYM = YYM_DATE + 13;
```

Otherwise, a non-full component date must be converted to a full component date before using DATEADD.

**DATECVT: Converting the Format of a Date**

The DATECVT function converts the field value of any standard date format or legacy date format into a date format (offset from the base date), in the desired standard date format or legacy date format. If you supply an invalid format, DATECVT returns a zero or a blank.
Syntax: 

**How to Convert a Date Format**

\[
\text{DATECVT}(date, 'in\_format', output)
\]

where:

\textit{date}  
Date  
Is the date to be converted. If you supply an invalid date, DATECVT returns zero. When the conversion is performed, a legacy date obeys any DEFCENT and YRTHRESH parameter settings supplied for that field.

\textit{in\_format}  
Alphanumeric  
Is the format of the date enclosed in single quotation marks. It is one of the following:

- A non-legacy date format (for example, YYMD, YQ, M, DMY, JUL).
- A legacy date format (for example, I6YMD or A8MDYY).
- A non-date format (such as I8 or A6). A non-date format in \textit{in\_format} functions as an offset from the base date of a YYMD field (12/31/1900).

\textit{output}  
Alphanumeric  
Is the output format. It is one of the following:

- A non-legacy date format (for example, YYMD, YQ, M, DMY, JUL).
- A legacy date format (for example, I6YMD or A8MDYY).
- A non-date format (such as I8 or A6). This format type causes DATECVT to convert the date into a full component date and return it as a whole number in the format provided.

Example: 

**Converting the Format of a Date**

This example first converts a numeric date, NUMDATE, to a character date, and then assigns the result to a non-date alphanumeric field, CHARDATE.

\[
\text{CHARDATE/A13 = DATECVT (NUMDATE, 'I8YYMD', 'A8YYMD');}
\]

**Note:** DATECVT does not use an output format; it uses the format of the argument output_format for the result.
DATEDIF: Finding the Difference Between Two Dates

The DATEDIF function returns the difference between two full component standard dates in units of a specified component. A component is one of the following:

- **Year.** Using the year unit with DATEDIF yields the inverse of DATEADD. If subtracting one year from date X creates date Y, then the count of years between X and Y is one. Subtracting one year from February 29 produces the date February 28.

- **Month.** Using the month component with DATEDIF yields the inverse of DATEADD. If subtracting one month from date X creates date Y, then the count of months between X and Y is one. If the to-date is the end-of-month, then the month difference may be rounded up (in absolute terms) to guarantee the inverse rule.

  If one or both of the input dates is the end of the month, DATEDIF takes this into account. This means that the difference between January 31 and April 30 is three months, not two months.

- **Day.**

- **Weekday.** With the weekday unit, DATEDIF does not count Saturday or Sunday when calculating days. This means that the difference between Friday and Monday is one day.

- **Business day.** With the business day unit, DATEDIF uses the BUSDAYS parameter setting and holiday file to determine which days are working days and disregards the rest. This means that if Monday is not a working day, the difference between Friday and Tuesday is one day. See *Rules for Creating a Holiday File* on page 198 for more information.

DATEDIF returns a whole number. If the difference between two dates is not a whole number, DATEDIF truncates the value to the next largest integer. For example, the number of years between March 2, 2001, and March 1, 2002, is zero. If the end date is before the start date, DATEDIF returns a negative number.

Since Dialogue Manager interprets a date as alphanumeric or numeric, and DATEDIF requires a standard date stored as an offset from the base date, do not use DATEDIF with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date.
**Syntax:** How to Find the Difference Between Two Dates

DATEDIF('from_date', 'to_date', 'component')

where:

*from_date*  
Date  
Is the start date from which to calculate the difference. Is a full component date.

*to_date*  
Date  
Is the end date from which to calculate the difference.

*component*  
Alphanumeric  
Is one of the following enclosed in single quotation marks:

- **Y** indicates a year unit.
- **M** indicates a month unit.
- **D** indicates a day unit.
- **WD** indicates a weekday unit.
- **BD** indicates a business day unit.

**Note:** DATEDIF does not use an output argument because for the result it uses the format 'I8'.

**Example:** Finding the Difference Between Two Dates

The example finds the number of complete months between today, March 23, 2004, and one specific day in the past

DATEDIF('September 11 2001', '20040323', 'M')

and returns 30, which can be assigned to a numeric field.

**Tip:** There is an alternative way to find the difference between dates. As long as any standard date is presented internally as a whole number of the least significant component units (that is, a number of days for full component dates, a number of months for YYM or MY format dates, etc.), you can find the difference in these component units (not any units) directly, without DATEDIF. For example, assume OLD_YYM_DT is a date field in format MYY and NEW_YYM_DT is another date in format YYM. Note that the least significant component for both formats is month, M. The difference in months, then, can be found by subtracting the field OLD_YYM_DT from NEW_YYM_DT in the following statement:
Otherwise, non-full component standard dates or legacy dates should be converted to full component standard dates before using DATEDIF.

**DATEMOV: Moving a Date to a Significant Point**

The DATEMOV function moves a date to a significant point on the calendar.

**Note:** Using the beginning of week point (BOW) will always return Monday, and using the end of week point (EOW) will always return Friday. Also, if the date used with the DATEMOV function falls on Saturday or Sunday, the actual date used by the function will be the moved forward to the next Monday. If you do not want to do the calculation by moving the date from Saturday or Sunday to Monday, or if you want the BOW to be Sunday and the EOW to be Saturday, you can use the DTRUNC function.

Since Dialogue Manager interprets a date as alphanumeric or numeric, and DATEMOV requires a standard date stored as an offset from the base date, do not use DATEMOV with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date. For example, the following converts the integer legacy date 20050131 to a smart date, adds one month, and converts the result to an alphanumeric legacy date:

```plaintext
-SET &STRT=DATECVT(20050131,©I8YYMD©, ©YYMD©);
-SET &NMT=DATEADD(&STRT,©M©,1);
-SET &NMTA=DATECVT(&NMT,©YYMD©,©A8MTDYY©);
-TYPE A MONTH FROM 20050131 IS &NMTA
```

The output shows that the DATEADD function added the actual number of days in the month of February to get to the end of the month from the end of January:

```
A MONTH FROM 20050131 IS 02282005
```

DATEMOV works only with full component dates.

**Syntax:** How to Move a Date to a Significant Point

```
DATEMOV(date, 'move-point')
```

where:

- **date**
  - Date
  - Is the date to be moved. It must be a full component format date (for example, MDYY or YYJUL).
move-point
Alphanumeric

Is the significant point the date is moved to enclosed in single quotation marks ('). An invalid point results in a return code of zero. Valid values are:

- **EOM**, which is the end of month.
- **BOM**, which is the beginning of month.
- **EOQ**, which is the end of quarter.
- **BOQ**, which is the beginning of quarter.
- **EOY**, which is the end of year.
- **BOY**, which is the beginning of year.
- **EOW**, which is the end of week.
- **BOW**, which is the beginning of week.
- **NWD**, which is the next weekday.
- **NBD**, which is the next business day.
- **PWD**, which is the prior weekday.
- **PBD**, which is the prior business day.
- **WD-**, which is a weekday or earlier.
- **BD-**, which is a business day or earlier.
- **WD+**, which is a weekday or later.
- **BD+**, which is a business day or later.

A business day calculation is affected by the BUSDAYS and HDAY parameter settings.

Note that when the DATEADD function calculates the next or previous business day or work day, it always starts from a business day or work day. So if the actual day is Saturday or Sunday, and the request wants to calculate the next business day, the function will use Monday as the starting day, not Saturday or Sunday, and will return Tuesday as the next business day. Similarly, when calculating the previous business day, it will use the starting day Friday, and will return Thursday as the previous business day.
To avoid skipping a business day or work day, use DATEMOV. To return the next business or work day, use BD- or WD- to first move to the previous business or work day (if it is already a business day or work day, it will not be moved). Then use DATEADD to move to the next business or work day. If you want to return the previous business or work day, first use BD+ or WD+ to move to the next business or work day (if it is already the correct type of day, it will not be moved). Then use DATEADD to return the previous business or work day.

**Note:** DATEMOV does not use an output argument. It uses the format of the date argument for the result. As long as the result is a full component date, it can be assigned only to a full component date field or to an integer field.

**Example:** Moving a Date to a Significant Point

This example finds the end day of the current date week

```
DATEDIF('&YYMD', 'EOW')
```

and returns 20040326 if today is 2004, March 23rd. Note the use of the system variable &YYMD and natural date representation in the first argument.

**Example:** Returning the Next Business Day

This example shows why you may need to use DATEMOV to get the correct result.

The following request against the GGSALES data source uses the BD (Business Day) move point against the DATE field. First DATE is converted to a smart date, then DATEADD is called with the BD move-point:

```
DEFINE FILE GGSALES
  DT1/WMDYY=DATE;
  DT2/WMDYY = DATEADD(DT1 , 'BD', 1);
  DAY/Dt = DT1;
  END

TABLE FILE GGSALES
  SUM  DT1
  DT2
  BY DT1 NOPRINT
  WHERE RECORDLIMIT EQ 10
  END
```
When the date is on a Saturday or Sunday on the output, the next business day is returned as a Tuesday. This is because before doing the calculation, the original date was moved to a business day:

<table>
<thead>
<tr>
<th>DT1</th>
<th>DT2</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUN, 09/01/1996</td>
<td>TUE, 09/03/1996</td>
</tr>
<tr>
<td>FRI, 11/01/1996</td>
<td>MON, 11/04/1996</td>
</tr>
<tr>
<td>SUN, 12/01/1996</td>
<td>TUE, 12/03/1996</td>
</tr>
<tr>
<td>SAT, 03/01/1997</td>
<td>TUE, 03/04/1997</td>
</tr>
<tr>
<td>TUE, 04/01/1997</td>
<td>WED, 04/02/1997</td>
</tr>
<tr>
<td>THU, 05/01/1997</td>
<td>FRI, 05/02/1997</td>
</tr>
<tr>
<td>SUN, 06/01/1997</td>
<td>TUE, 06/03/1997</td>
</tr>
<tr>
<td>MON, 09/01/1997</td>
<td>TUE, 09/02/1997</td>
</tr>
<tr>
<td>WED, 10/01/1997</td>
<td>THU, 10/02/1997</td>
</tr>
</tbody>
</table>

In the following version of the request, DATEMOV is called to make sure the starting day is a business day. The move point specified in the first call is BD- which only moves the date to the prior business day if it is not already a business day. The call to DATEADD then uses the BD move point to return the next business day:

```plaintext
DEFINE FILE GGSALES
DT1/WMDYY=DATE;
DT1A/WMDYY=DATEMOV(DT1, 'BD-');
DT2/WMDYY = DATEADD(DT1A, 'BD', 1);
DAY/Dt = DT1;
END

TABLE FILE GGSALES
SUM DT1 DT1A DT2
BY DT1 NOPRINT
WHERE RECORDLIMIT EQ 10
END
```

On the output, the next business day after a Saturday or Sunday is now returned as Monday:

<table>
<thead>
<tr>
<th>DT1</th>
<th>DT1A</th>
<th>DT2</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUN, 09/01/1996</td>
<td>FRI, 08/30/1996</td>
<td>MON, 09/02/1996</td>
</tr>
<tr>
<td>SAT, 03/01/1997</td>
<td>FRI, 02/28/1997</td>
<td>MON, 03/03/1997</td>
</tr>
<tr>
<td>TUE, 04/01/1997</td>
<td>TUE, 04/01/1997</td>
<td>WED, 04/02/1997</td>
</tr>
<tr>
<td>THU, 05/01/1997</td>
<td>THU, 05/01/1997</td>
<td>FRI, 05/02/1997</td>
</tr>
<tr>
<td>SUN, 06/01/1997</td>
<td>FRI, 05/30/1997</td>
<td>MON, 06/02/1997</td>
</tr>
<tr>
<td>MON, 09/01/1997</td>
<td>MON, 09/01/1997</td>
<td>TUE, 09/02/1997</td>
</tr>
<tr>
<td>WED, 10/01/1997</td>
<td>WED, 10/01/1997</td>
<td>THU, 10/02/1997</td>
</tr>
</tbody>
</table>
**Example:** Using a DEFINE FUNCTION to Move a Date to the Beginning of the Week

The following DEFINE FUNCTION named BOWK takes a date and the name of the day you want to consider the beginning of the week and returns a date that corresponds to the beginning of the week:

```plsql
DEFINE FUNCTION BOWK(THEDATE/MDYY, WEEKSTART/A10)
  DAYOFWEEK/W=THEDATE;
  DAYNO/I1=IF DAYOFWEEK EQ 7 THEN 0 ELSE DAYOFWEEK;
  FIRSTOFWK/I1=DECODE WEEKSTART('SUNDAY' 0 'MONDAY' 1 'TUESDAY' 2 'WEDNESDAY' 3 'THURSDAY' 4 'FRIDAY' 5 'SATURDAY' 6 'SUN' 0 'MON' 1 'TUE' 2 'WED' 3 'THU' 4 'FRI' 5 'SAT' 6);
  BOWK/MDYY=IF DAYNO GE FIRSTOFWK THEN THEDATE-DAYNO+FIRSTOFWK ELSE THEDATE-7-DAYNO+FIRSTOFWK;
END
```

The following request uses the BOWK function to return a date (DT2) that corresponds to the beginning of the week for each value of the DT1 field:

```plsql
DEFINE FILE GGSALES
  DT1/WMDYY=DATE;
  DT2/WMDYY = BOWK(DT1, 'SUN');
END

TABLE FILE GGSALES
  SUM DT1
  DT2
  BY DT1 NOPRINT
  WHERE RECORDLIMIT EQ 10
  ON TABLE SET PAGE NOLEAD
END
```

The output is shown in the following image:
DATETRAN: Formatting Dates in International Formats

The DATETRAN function formats dates in international formats.

**Syntax:**

```
DATETRAN (indate, '(intype)', '([formatops])', 'lang', outlen, output)
```

where:

*indate*

Is the input date (in date format) to be formatted. Note that the date format cannot be an alphanumeric or numeric format with date display options (legacy date format).
**intype**

Is one of the following character strings indicating the input date components and the order in which you want them to display, enclosed in parentheses and single quotation marks.

The following table shows the single component input types:

<table>
<thead>
<tr>
<th>Single Component Input Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>' (W) '</td>
<td>Day of week component only (original format must have only W component).</td>
</tr>
<tr>
<td>' (M) '</td>
<td>Month component only (original format must have only M component).</td>
</tr>
</tbody>
</table>

The following table shows the two-component input types:

<table>
<thead>
<tr>
<th>Two-Component Input Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>' (YYM) '</td>
<td>Four-digit year followed by month.</td>
</tr>
<tr>
<td>' (YM) '</td>
<td>Two-digit year followed by month.</td>
</tr>
<tr>
<td>' (MYY) '</td>
<td>Month component followed by four-digit year.</td>
</tr>
<tr>
<td>' (MY) '</td>
<td>Month component followed by two-digit year.</td>
</tr>
</tbody>
</table>

The following table shows the three-component input types:

<table>
<thead>
<tr>
<th>Three-Component Input Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>' (YYMD) '</td>
<td>Four-digit year followed by month followed by day.</td>
</tr>
<tr>
<td>' (YMD) '</td>
<td>Two-digit year followed by month followed by day.</td>
</tr>
<tr>
<td>' (DMYY) '</td>
<td>Day component followed by month followed by four-digit year.</td>
</tr>
<tr>
<td>Three-Component Input Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'(DMY)'</td>
<td>Day component followed by month followed by two-digit year.</td>
</tr>
<tr>
<td>'(MDYY)'</td>
<td>Month component followed by day followed by four-digit year.</td>
</tr>
<tr>
<td>'(MDY)'</td>
<td>Month component followed by day followed by two-digit year.</td>
</tr>
<tr>
<td>'(MD)'</td>
<td>Month component followed by day (derived from three-component date by ignoring year component).</td>
</tr>
<tr>
<td>'(DM)'</td>
<td>Day component followed by month (derived from three-component date by ignoring year component).</td>
</tr>
</tbody>
</table>

formatops

Is a string of zero or more formatting options enclosed in parentheses and single quotation marks. The parentheses and quotation marks are required even if you do not specify formatting options. Formatting options fall into the following categories:

- Options for suppressing initial zeros in month or day numbers.

  **Note:** Zero suppression replaces initial zeros with blanks spaces.

- Options for translating month or day components to full or abbreviated uppercase or default case (mixed-case or lowercase depending on the language) names.

- Date delimiter options and options for punctuating a date with commas.

Valid options for suppressing initial zeros in month or day numbers are listed in the following table. Note that the initial zero is replaced by a blank space:

<table>
<thead>
<tr>
<th>Format Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>Zero-suppresses months (displays numeric months before October as 1 through 9 rather than 01 through 09).</td>
</tr>
</tbody>
</table>
### Format Option

<table>
<thead>
<tr>
<th>Format Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Displays days before the tenth of the month as 1 through 9 rather than 01 through 09.</td>
</tr>
<tr>
<td>dp</td>
<td>Displays days before the tenth of the month as 1 through 9 rather than 01 through 09 with a period after the number.</td>
</tr>
<tr>
<td>do</td>
<td>Displays days before the tenth of the month as 1 through 9. For English (langcode EN) only, displays an ordinal suffix (st, nd, rd, or th) after the number.</td>
</tr>
</tbody>
</table>

The following table shows valid month and day name translation options:

<table>
<thead>
<tr>
<th>Format Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Displays month as an abbreviated name, with no punctuation, all uppercase.</td>
</tr>
<tr>
<td>TR</td>
<td>Displays month as a full name, all uppercase.</td>
</tr>
<tr>
<td>Tp</td>
<td>Displays month as an abbreviated name, followed by a period, all uppercase.</td>
</tr>
<tr>
<td>t</td>
<td>Displays month as an abbreviated name with no punctuation. The name is all lowercase or initial uppercase, depending on language code.</td>
</tr>
<tr>
<td>tr</td>
<td>Displays month as a full name. The name is all lowercase or initial uppercase, depending on language code.</td>
</tr>
<tr>
<td>tp</td>
<td>Displays month as an abbreviated name, followed by a period. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>Format Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>W</td>
<td>Includes an abbreviated day-of-the-week name at the start of the displayed date, all uppercase with no punctuation.</td>
</tr>
<tr>
<td>WR</td>
<td>Includes a full day-of-the-week name at the start of the displayed date, all uppercase.</td>
</tr>
<tr>
<td>Wp</td>
<td>Includes an abbreviated day-of-the-week name at the start of the displayed date, all uppercase, followed by a period.</td>
</tr>
<tr>
<td>w</td>
<td>Includes an abbreviated day-of-the-week name at the start of the displayed date with no punctuation. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>wr</td>
<td>Includes a full day-of-the-week name at the start of the displayed date. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>wp</td>
<td>Includes an abbreviated day-of-the-week name at the start of the displayed date followed by a period. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>X</td>
<td>Includes an abbreviated day-of-the-week name at the end of the displayed date, all uppercase with no punctuation.</td>
</tr>
<tr>
<td>XR</td>
<td>Includes a full day-of-the-week name at the end of the displayed date, all uppercase.</td>
</tr>
<tr>
<td>Format Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Xp</td>
<td>Includes an abbreviated day-of-the-week name at the end of the displayed date, all uppercase, followed by a period.</td>
</tr>
<tr>
<td>x</td>
<td>Includes an abbreviated day-of-the-week name at the end of the displayed date with no punctuation. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>xr</td>
<td>Includes a full day-of-the-week name at the end of the displayed date. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
<tr>
<td>xp</td>
<td>Includes an abbreviated day-of-the-week name at the end of the displayed date followed by a period. The name displays in the default case of the specified language (for example, all lowercase for French and Spanish, initial uppercase for English and German).</td>
</tr>
</tbody>
</table>

The following table shows valid date delimiter options:

<table>
<thead>
<tr>
<th>Format Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Uses a blank as the component delimiter. This is the default if the month or day of week is translated or if comma is used.</td>
</tr>
<tr>
<td>.</td>
<td>Uses a period (.) as the component delimiter.</td>
</tr>
<tr>
<td>–</td>
<td>Uses a minus sign (-) as the component delimiter. This is the default when the conditions for a blank default delimiter are not satisfied.</td>
</tr>
<tr>
<td>Format Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>/</td>
<td>Uses a slash (/) as the component delimiter.</td>
</tr>
<tr>
<td></td>
<td>Omits component delimiters.</td>
</tr>
<tr>
<td>K</td>
<td>Uses appropriate Asian characters as component delimiters.</td>
</tr>
<tr>
<td>c</td>
<td>Places a comma (,) after the month name (following T, Tp, TR, t, tp, or tr).</td>
</tr>
<tr>
<td></td>
<td>Places a comma and blank after the day name (following W, Wp, WR, w, wp, or wr).</td>
</tr>
<tr>
<td></td>
<td>Places a comma and blank before the day name (following X, XR, x, or xr).</td>
</tr>
<tr>
<td>e</td>
<td>Displays the Spanish or Portuguese word de or DE between the day and month, and between the month and year. The case of the word de is determined by the case of the month name. If the month is displayed in uppercase, DE is displayed. Otherwise, de is displayed. Useful for formats DMY, DMYY, MY, and MYY.</td>
</tr>
<tr>
<td>D</td>
<td>Inserts a comma (,) after the day number and before the general delimiter character specified.</td>
</tr>
<tr>
<td>Y</td>
<td>Inserts a comma (,) after the year and before the general delimiter character specified.</td>
</tr>
</tbody>
</table>

**lang**

Is the two-character standard ISO code for the language into which the date should be translated, enclosed in single quotation marks ('). Valid language codes are:

- 'AR' Arabic
- 'CS' Czech
- 'DA' Danish
- 'DE' German
'EN' English
'ES' Spanish
'FI' Finnish
'FR' French
'EL' Greek
'IW' Hebrew
'IT' Italian
'JA' Japanese
'KO' Korean
'LT' Lithuanian
'NL' Dutch
'NO' Norwegian
'PO' Polish
'PT' Portuguese
'RU' Russian
'SV' Swedish
'TH' Thai
'TR' Turkish
'TW' Chinese (Traditional)
'ZH' Chinese (Simplified)

outlen
Numeric

Is the length of the output field in bytes. If the length is insufficient, an all blank result is returned. If the length is greater than required, the field is padded with blanks on the right.

output
Alphanumeric
**Usage Notes for the DATETRAN Function**

- The output field, though it must be type A, and not AnV, may in fact contain variable length information, since the lengths of month names and day names can vary, and also month and day numbers may be either one or two bytes long if a zero-suppression option is selected. Unused bytes are filled with blanks.

- All invalid and inconsistent inputs result in all blank output strings. Missing data also results in blank output.

- The base dates (1900-12-31 and 1900-12 or 1901-01) are treated as though the DATEDISPLAY setting were ON (that is, not automatically shown as blanks). To suppress the printing of base dates, which have an internal integer value of 0, test for 0 before calling DATETRAN. For example:

```plaintext
RESULT/A40 = IF DATE EQ 0 THEN '' ELSE
DATETRAN (DATE, '(YYMD)', '(d)', 'FR', 40, 'A40');
```

- Valid translated date components are contained in files named DTLNGlng where lng is a three-character code that specifies the language. These files must be accessible for each language into which you want to translate dates.

- The DATETRAN function is not supported in Dialogue Manager.
**Example:** Using the DATETRAN Function

The following request prints the day of the week in the default case of the specific language:

```sql
DEFINE FILE VIDEOTRK
TRANS1/YYMD=20050104;
TRANS2/YYMD=20051003;

DATEW/W=TRANS1 ;
DATEW2/W=TRANS2 ;
DATEYYMD/YYMDW=TRANS1 ;
DATEYYMD2/YYMDW=TRANS2 ;

OUT1A/A8=DATETRAN(DATEW, '(W)', '(wr)', 'EN', 8 , 'A8') ;
OUT1B/A8=DATETRAN(DATEW2, '(W)', '(wr)', 'EN', 8 , 'A8') ;
OUT1C/A8=DATETRAN(DATEW, '(W)', '(wr)', 'ES', 8 , 'A8') ;
OUT1D/A8=DATETRAN(DATEW2, '(W)', '(wr)', 'ES', 8 , 'A8') ;
OUT1E/A8=DATETRAN(DATEW, '(W)', '(wr)', 'FR', 8 , 'A8') ;
OUT1F/A8=DATETRAN(DATEW2, '(W)', '(wr)', 'FR', 8 , 'A8') ;
OUT1G/A8=DATETRAN(DATEW, '(W)', '(wr)', 'DE', 8 , 'A8') ;
OUT1H/A8=DATETRAN(DATEW2, '(W)', '(wr)', 'DE', 8 , 'A8') ;
END

TABLE FILE VIDEOTRK
HEADING
"FORMAT wr"
""
"Full day of week name at beginning of date, default case (wr)"
"English / Spanish / French / German"
""
SUM OUT1A AS '' OUT1B AS '' TRANSDATE NOPRINT
OVER OUT1C AS '' OUT1D AS ''
OVER OUT1E AS '' OUT1F AS ''
OVER OUT1G AS '' OUT1H AS ''
ON TABLE SET PAGE-NUM OFF
ON TABLE SET STYLE *
GRID=OFF, $ 
END
```
The output is:

```plaintext
FORMAT wr

Full day of week name at beginning of date, default case (wr)
English / Spanish / French / German

Tuesday       Monday
martes        lunes
mardi         lundi
Dienstag      Montag
```

The following request prints a blank delimited date with an abbreviated month name in English. Initial zeros in the day number are suppressed, and a suffix is added to the end of the number:

```plaintext
DEFINE FILE VIDEOTRK
TRANS1/YYMD=20050104;
TRANS2/YYMD=20050302;

DATEW/W=TRANS1     ;
DATEW2/W=TRANS2    ;
DATEYYMD/YYMDW=TRANS1    ;
DATEYYMD2/YYMDW=TRANS2   ;

OUT2A/A15=DATETRAN(DATEYYMD, ©(MDYY)©, ©(Btdo)©, ©EN©, 15, ©A15©) ;
OUT2B/A15=DATETRAN(DATEYYMD2, ©(MDYY)©, ©(Btdo)©, ©EN©, 15, 'A15') ;
END

TABLE FILE VIDEOTRK
HEADING
"FORMAT Btdo"
"
"Blank-delimited (B)"
"Abbreviated month name, default case (t)"
"Zero-suppress day number, end with suffix (do)"
"English"
"
SUM OUT2A AS '' OUT2B AS '' TRANSDATE NOPRINT
ON TABLE SET PAGE-NUM OFF
END
```
The following request prints a blank delimited date, with an abbreviated month name in German. Initial zeros in the day number are suppressed, and a period is added to the end of the number:

```
DEFINE FILE VIDEOTRK
TRANS1/YYMD=20050104;
TRANS2/YYMD=20050302;

DATEW/W=TRANS1     ;
DATEW2/W=TRANS2    ;
DATEYYMD/YYMDW=TRANS1    ;
DATEYYMD2/YYMDW=TRANS2   ;

**FIYR: Obtaining the Financial Year**

The FIYR function returns the financial year, also known as the fiscal year, corresponding to a given calendar date based on the financial year starting date and the financial year numbering convention.

Since Dialogue Manager interprets a date as alphanumeric or numeric, and FIYR requires a standard date stored as an offset from the base date, do not use FIYR with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date.

**Syntax:**

**How to Obtain the Financial Year**

```
FIYR(inputdate, lowcomponent, startmonth, startday, yrnumbering, output)
```

where:

**inputdate**

Date

Is the date for which the financial year is returned. The date must be a standard date stored as an offset from the base date.

If the financial year does not begin on the first day of a month, the date must have Y(Y), M, and D components, or Y(Y) and JUL components (note that JUL is equivalent to YJUL). Otherwise, the date only needs Y(Y) and M components or Y(Y) and Q components.

**lowcomponent**

Alphanumeric
Is one of the following:

- **D** if the date contains a D or JUL component.
- **M** if the date contains an M component, but no D component.
- **Q** if the date contains a Q component.

**startmonth**

Numeric

1 through 12 are used to represent the starting month of the financial year, where 1 represents January and 12 represents December. If the low component is Q, the start month must be 1, 4, 7, or 10.

**startday**

Numeric

Is the starting day of the starting month, usually 1. If the low component is M or Q, 1 is required.

**yrnumbering**

Alphanumeric

Valid values are:

- **FYE** to specify the *Financial Year Ending* convention. The financial year number is the calendar year of the ending date of the financial year. For example, when the financial year starts on October 1, 2008, the date 2008 November 1 is in FY 2009 Q1 because that date is in the financial year that ends on 2009 September 30.

- **FYS** to specify the *Financial Year Starting* convention. The financial year number is the calendar year of the starting date of the financial year. For example, when the financial year starts on April 6, 2008, the date 2008 July 6 is in FY 2008 Q2 because that date is in the financial year that starts on 2008 April 6.

**output**

I, Y, or YY

The result will be in integer format, or Y or YY. This function returns a year value. In case of an error, zero is returned.

**Note:** February 29 cannot be used as a start day for a financial year.
**Example:** Obtaining the Financial Year

FIYR obtains the financial year for PERIOD, which has format YYM:

\[
\text{FIYR(PERIOD, 'M', 4, 1, 'FYE', 'YY')};
\]

For PERIOD 2002/03, the result is 2002

For PERIOD 2002/04, the result is 2003.

**FIQTR: Obtaining the Financial Quarter**

The FIQTR function returns the financial quarter corresponding to a given calendar date based on the financial year starting date and the financial year numbering convention.

Since Dialogue Manager interprets a date as alphanumeric or numeric, and FIQTR requires a standard date stored as an offset from the base date, do not use FIQTR with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date.

**Syntax:** How to Obtain the Financial Quarter

\[
\text{FIQTR(inputdate, lowcomponent, startmonth, startday, yrnumbering, output)}
\]

where:

- **inputdate**
  
  **Date**

  Is the date for which the financial year is returned. The date must be a standard date stored as an offset from the base date.

  If the financial year does not begin on the first day of a month, the date must have Y(Y), M, and D components, or Y(Y) and JUL components (note that JUL is equivalent to YJUL). Otherwise, the date only needs Y(Y) and M components or Y(Y) and Q components.

- **lowcomponent**
  
  **Alphabetic**

  Is one of the following:

  - **D** if the date contains a D or JUL component.
  - **M** if the date contains an M component, but no D component.
  - **Q** if the date contains a Q component.
**startmonth**

Numeric

1 through 12 are used to represent the starting month of the financial year, where 1 represents January and 12 represents December. If the low component is Q, the start month must be 1, 4, 7, or 10.

**startday**

Numeric

Is the starting day of the starting month, usually 1. If the low component is M or Q, 1 is required.

**yrnumbering**

Alphanumeric

Valid values are:

FYE to specify the Financial Year Ending convention. The financial year number is the calendar year of the ending date of the financial year. For example, when the financial year starts on October 1, 2008, the date 2008 November 1 is in FY 2009 Q1 because that date is in the financial year that ends on 2009 September 30.

FYS to specify the Financial Year Starting convention. The financial year number is the calendar year of the starting date of the financial year. For example, when the financial year starts on April 6, 2008, the date 2008 July 6 is in FY 2008 Q2 because that date is in the financial year that starts on 2008 April 6.

**output**

I or Q

The result will be in integer format, or Q. This function will return a value of 1 through 4. In case of an error, zero is returned.

**Note:** February 29 cannot be used as a start day for a financial year.

**Example:** Obtaining the Financial Quarter

FIQTR obtains the financial quarter for START_DATE (format YYMD) and returns a column with format Q;

FIQTR(START_DATE,'D',10,1,'FYE','Q');

For 1997/10/01, the result is Q1.
For 1996/07/30, the result is Q4.
FIYYQ: Converting a Calendar Date to a Financial Date

The FIYYQ function returns a financial date containing both the financial year and quarter that corresponds to a given calendar date. The returned financial date is based on the financial year starting date and the financial year numbering convention.

Since Dialogue Manager interprets a date as alphanumeric or numeric, and FIYYQ requires a standard date stored as an offset from the base date, do not use FIYYQ with Dialogue Manager unless you first convert the variable used as the input date to an offset from the base date.

Syntax:

How to Convert a Calendar Date to a Financial Date

\[ \text{FIYYQ}(\text{inputdate}, \text{lowcomponent}, \text{startmonth}, \text{startday}, \text{yrnumbering}, \text{output}) \]

where:

\text{inputdate}

Is the date for which the financial year is returned. The date must be a standard date stored as an offset from the base date.

If the financial year does not begin on the first day of a month, the date must have Y(Y), M, and D components, or Y(Y) and JUL components (note that JUL is equivalent to YJUL). Otherwise, the date only needs Y(Y) and M components or Y(Y) and Q components.

\text{lowcomponent}

Is one of the following:

- \( \text{D} \) if the date contains a D or JUL component.
- \( \text{M} \) if the date contains an M component, but no D component.
- \( \text{Q} \) if the date contains a Q component.

\text{startmonth}

Is the starting month of the financial year, where 1 represents January and 12 represents December. If the low component is Q, the start month must be 1, 4, 7, or 10.

**startday**

Numeric

Is the starting day of the starting month, usually 1. If the low component is M or Q, 1 is required.

**yrnumbering**

Alphanumeric

Valid values are:

*FYE* to specify the *Financial Year Ending* convention. The financial year number is the calendar year of the ending date of the financial year. For example, when the financial year starts on October 1, 2008, the date 2008 November 1 is in FY 2009 Q1 because that date is in the financial year that ends on 2009 September 30.

*FYS* to specify the *Financial Year Starting* convention. The financial year number is the calendar year of the starting date of the financial year. For example, when the financial year starts on April 6, 2008, the date 2008 July 6 is in FY 2008 Q2 because that date is in the financial year that starts on 2008 April 6.

**output**

Y[Y]Q or QY[Y]

In case of an error, zero is returned.

**Note:** February 29 cannot be used as a start day for a financial year.

**Example:**  **Converting a Calendar Date to a Financial Date**

FIYYQ returns the financial date in format YQ that corresponds to START_DATE (format YYMD);

FIYYQ(START_DATE,'D',10,1,'FYE','YQ');

For 1997/10/01, the result is 98 Q1.

For 1996/07/30, the result is 96 Q4.

**TODAY: Returning the Current Date**

The TODAY function retrieves the current date from the operating system in the format MM/DD/YY or MM/DD/YYYY. It always returns a date that is current. Therefore, if you are running an application late at night, use TODAY. You can remove the default embedded slashes with the EDIT function.
You can also retrieve the date in the same format (separated by slashes) using the Dialogue Manager system variable &DATE. You can retrieve the date without the slashes using the system variables &YMD, &MDY, and &DMY. The system variable &DATEfmt retrieves the date in a specified format.

**Syntax:** How to Retrieve the Current Date

```plaintext
TODAY(output)
```

where:

`output`

- Alphanumeric, at least A8

The following apply:

- If the format is A8 or A9, TODAY returns the 2-digit year.
- If the format is A10 or greater, TODAY returns the 4-digit year.

**Example:** Retrieving the Current Date

TODAY retrieves the current date and stores it in a column with the format A10.

```plaintext
TODAY('A10')
```

**Using Legacy Date Functions**

The legacy date functions were created for use with dates in integer, packed decimal, or alphanumeric format.

For detailed information on each legacy date function, see:

- `AYM: Adding or Subtracting Months` on page 237
- `AYMD: Adding or Subtracting Days` on page 237
- `CHGDAT: Changing How a Date String Displays` on page 238
- `DA Functions: Converting a Legacy Date to an Integer` on page 241
- `DMY, MDY, YMD: Calculating the Difference Between Two Dates` on page 242
- `DOWK and DOWKL: Finding the Day of the Week` on page 242
- `DT Functions: Converting an Integer to a Date` on page 243
- `GREGDT: Converting From Julian to Gregorian Format` on page 244
Using Old Versions of Legacy Date Functions

The functions described in this section are legacy date functions. They were created for use with dates in integer or alphanumeric format. They are no longer recommended for date manipulation. Standard date and date-time functions are preferred.

All legacy date functions support dates for the year 2000 and later.

AYMD: Adding or Subtracting Days

The AYMD function adds days to or subtracts days from a date in year-month-day format. You can convert a date to this format using the CHGDAT or EDIT function.

Syntax:  How to Add or Subtract Days to or From a Date

AYMD(indate, days, output)

where:

indate

I6, I6YMD, I8, I8YYMD

Is the legacy date in year-month-day format. If the date is not valid, the function returns the value 0 (zero).

days

Integer

Is the number of days you are adding to or subtracting from indate. To subtract days, use a negative number.

output

I6, I6YMD, I8, or I8YYMD

Is the same format as indate.

If the addition or subtraction of days crosses forward or backward into another century, the century digits of the output year are adjusted.
CHGDAT: Changing How a Date String Displays

Example:  Adding Days to a Date

AYMD adds 35 days to each value in the HIRE_DATE field, and stores the result in a column with the format I6YMD.

AYMD(HIRE_DATE, 35, 'I6YMD')

For 99/08/01, the result is 99/09/05.
For 99/01/04, the result is 99/02/08.

CHGDAT: Changing How a Date String Displays

The CHGDAT function rearranges the year, month, and day portions of an input character string representing a date. It may also convert the input string from long to short or short to long date representation. Long representation contains all three date components: year, month, and day; short representation omits one or two of the date components, such as year, month, or day. The input and output date strings are described by display options that specify both the order of date components (year, month, day) in the date string and whether two or four digits are used for the year (for example, 04 or 2004). CHGDAT reads an input date character string and creates an output date character string that represents the same date in a different way.

Note: CHGDAT requires a date character string as input, not a date itself. Whether the input is a standard or legacy date, convert it to a date character string (using the EDIT or DATECVT functions, for example) before applying CHGDAT.

The order of date components in the date character string is described by display options comprised of the following characters in your chosen order:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Day of the month (01 through 31).</td>
</tr>
<tr>
<td>M</td>
<td>Month of the year (01 through 12).</td>
</tr>
<tr>
<td>Y[Y]</td>
<td>Year. Y indicates a two-digit year (such as 94); YY indicates a four-digit year (such as 1994).</td>
</tr>
</tbody>
</table>
To spell out the month rather than use a number in the resulting string, append one of the following characters to the display options for the resulting string:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Displays the month as a three-letter abbreviation.</td>
</tr>
<tr>
<td>X</td>
<td>Displays the full name of the month.</td>
</tr>
</tbody>
</table>

Display options can consist of up to five display characters. Characters other than those display options are ignored.

For example: The display options 'DMYY' specify that the date string starts with a two digit day, then two digit month, then four digit year.

**Note:** Display options are *not* date formats.

**Reference:** Short to Long Conversion

If you are converting a date from short to long representation (for example, from year-month to year-month-day), the function supplies the portion of the date missing in the short representation, as shown in the following table:

<table>
<thead>
<tr>
<th>Portion of Date Missing</th>
<th>Portion Supplied by Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day (for example, from YM to YMD)</td>
<td>Last day of the month.</td>
</tr>
<tr>
<td>Month (for example, from Y to YM)</td>
<td>Last month of the year (December).</td>
</tr>
<tr>
<td>Year (for example, from MD to YMD)</td>
<td>The year 99.</td>
</tr>
<tr>
<td>Converting year from two-digit to four-digit (for example, from YMD to YYMD)</td>
<td>The century will be determined by the 100-year window defined by DEFCENT and YRTHRESH.</td>
</tr>
</tbody>
</table>
**Syntax:** How to Change the Date Display String

CHGDAT('in_display_options','out_display_options',date_string,output)

where:

'**in_display_options**'

A1 to A5

Is a series of up to five display options that describe the layout of date_string. These options can be stored in an alphanumeric field or supplied as a literal enclosed in single quotation marks.

'**out_display_options**'

A1 to A5

Is a series of up to five display options that describe the layout of the converted date string. These options can be stored in an alphanumeric field or supplied as a literal enclosed in single quotation marks.

**date_string**

A2 to A8

Is the input date character string with date components in the order specified by in_display_options.

Note that if the original date is in numeric format, you must convert it to a date character string. If date_string does not correctly represent the date (the date is invalid), the function returns blank spaces.

**output**

Ax where xx is a number of characters large enough to fit the date string specified by out_display_options. A17 is long enough to fit the longest date string.

**Note:** Since CHGDAT uses a date string (as opposed to a date) and returns a date string with up to 17 characters, use the EDIT or DATECVT functions or any other means to convert the date to or from a date character string.

**Example:** Converting the Date Display From YMD to MDYYX

ALPHA_HIRE is HIRE_DATE converted from numeric to alphanumeric format. CHGDAT converts each value in ALPHA_HIRE from displaying the components as YMD to MDYYX and stores the result in a column with the format A17. The option X in the output value displays the full name of the month.
DA Functions: Converting a Legacy Date to an Integer

The DA functions convert a legacy date to the number of days between it and a base date. By converting a date to the number of days, you can add and subtract dates and calculate the intervals between them, or you can add to or subtract numbers from the dates to get new dates.

You can convert the result back to a date using the DT functions discussed in DT Functions: Converting an Integer to a Date on page 243.

There are six DA functions; each one accepts a date in a different format.

Syntax:  
How to Convert a Date to an Integer

\[ \text{function(indate, output)} \]

where:

\( \text{function} \)

Is one of the following:

- \( \text{DADMY} \) converts a date in day-month-year format.
- \( \text{DADYM} \) converts a date in day-year-month format.
- \( \text{DAMDY} \) converts a date in month-day-year format.
- \( \text{DAMYD} \) converts a date in month-year-day format.
- \( \text{DAYDM} \) converts a date in year-day-month format.
- \( \text{DAYMD} \) converts a date in year-month-day format.

\( \text{indate} \)

I6xxx or P6xxx, where xxx corresponds to the function DAxxx you are using.

Is the legacy date to be converted. If \( \text{indate} \) is a numeric literal, enter only the last two digits of the year; the function assumes the century component. If the date is invalid, the function returns a 0.

\( \text{output} \)

Integer
Example: Converting Dates and Calculating the Difference Between Them

DAYMD converts DAT_INC and HIRE_DATE to the number of days since December 31, 1899 and the smaller number is then subtracted from the larger number:

\[
\text{DAYMD(DAT\_INC, 'I8')} - \text{DAYMD(HIRE\_DATE, 'I8')}
\]

DMY, MDY, YMD: Calculating the Difference Between Two Dates

The DMY, MDY, and YMD functions calculate the difference between two legacy dates in integer, alphanumeric, or packed format.

Syntax: How to Calculate the Difference Between Two Dates

\[
\text{function(from_date, to_date)}
\]

where:

- **function**
  - Is one of the following:
    - **DMY** calculates the difference between two dates in day-month-year format.
    - **MDY** calculates the difference between two dates in month-day-year format.
    - **YMD** calculates the difference between two dates in year-month-day format.

- **from_date**
  - I, P, or A format with date display options.
  - Is the beginning legacy date.

- **to_date**
  - I, P, or A format with date display options.I6xxx or I8xxx where xxx corresponds to the specified function (DMY, YMD, or MDY).
  - Is the end date.

Example: Calculating the Number of Days Between Two Dates

YMD calculates the number of days between the dates in HIRE\_DATE and DAT\_INC.

\[
\text{YMD(HIRE\_DATE, DAT\_INC)}
\]

DOWK and DOWKL: Finding the Day of the Week

The DOWK and DOWKL functions find the day of the week that corresponds to a date. DOWK returns the day as a three letter abbreviation; DOWKL displays the full name of the day.
**Syntax:** How to Find the Day of the Week

```
{DOWK|DOWKL}(indate, output)
```

where:

- **indate**
  
  I6YMD or I8YYMD

  Is the legacy date in year-month-day format. If the date is not valid, the function returns spaces. If the date specifies a two digit year and DEFCENT and YRTHRESH values have not been set, the function assumes the 20th century.

- **output**

  DOWK: A4. DOWKL: A12

**Example:** Finding the Day of the Week

DOWK determines the day of the week that corresponds to the value in the HIRE_DATE field and stores the result in a column with the format A4.

```
DOWK(HIRE_DATE, 'A4')
```

For 80/06/02, the result is MON.

For 82/08/01, the result is SUN.

**DT Functions: Converting an Integer to a Date**

There are six DT functions; each one converts a number into a date of a different format.
**Syntax:** How to Convert an Integer to a Date

\[
\text{function(number, output)}
\]

where:

**function**

Is one of the following:

- **DTDMY** converts a number to a day-month-year date.
- **DTDYM** converts a number to a day-year-month date.
- **DTMDY** converts a number to a month-day-year date.
- **DTMYD** converts a number to a month-year-day date.
- **DTYDM** converts a number to a year-day-month date.
- **DTYMD** converts a number to a year-month-day date.

**number**

Integer

Is the number of days since the base date, possibly received from the functions DAxxx.

**output**

I8xxx, where xxx corresponds to the function DTxxx in the above list.

**Example:** Converting an Integer to a Date

DTMDY converts NEWF (which was converted to the number of days by DAYMD) to the corresponding date and stores the result in a column with the format I8MDYY.

\[
\text{DTMDY(NEWF, 'I8MDYY')}\]

For 81/11/02, the result is 11/02/1981.

For 82/05/01, the result is 05/01/1982.

**GREGDT:** Converting From Julian to Gregorian Format

The GREGDT function converts a date in Julian format (year-day) to Gregorian format (year-month-day).
A date in Julian format is a five- or seven-digit number. The first two or four digits are the year; the last three digits are the number of the day, counting from January 1. For example, January 1, 1999 in Julian format is either 99001 or 1999001; June 21, 2004 in Julian format is 2004173.

**Syntax:** How to Convert From Julian to Gregorian Format

```
GREGDT(indate, output)
```

where:

- **indate**
  - I5 or I7
  - Is the Julian date. If the date is invalid, the function returns a 0 (zero).

- **output**
  - I6, I8, I6YMD, or I8YYMD

**Example:** Converting From Julian to Gregorian Format

DTMDY converts NEWF (which was converted to the number of days by DAYMD) to the corresponding date and stores the result in a column with the format I8MDYY.

```
DTMDY(NEWF, 'I8MDYY')
```

For 81/11/02, the result is 11/02/1981.

For 82/05/01, the result is 05/01/1982.

**JULDAT: Converting From Gregorian to Julian Format**

The JULDAT function converts a date from Gregorian format (year-month-day) to Julian format (year-day). A date in Julian format is a five- or seven-digit number. The first two or four digits are the year; the last three digits are the number of the day, counting from January 1. For example, January 1, 1999 in Julian format is either 99001 or 1999001.
**Syntax:**  How to Convert From Gregorian to Julian Format

```
JULDAT(indate, output)
```

where:

- **indate**
  - I6, I8, I6YMD, I8YYMD
  - Is the legacy date to convert.

- **output**
  - I5 or I7

**Example:**  Converting From Gregorian to Julian Format

GREGDT converts JULIAN to YYMD (Gregorian) format. It determines the century using the default DEFDEFAULT and YRTHRESH parameter settings. The result is stored in a column with the format I8.

```
GREGDT(JULIAN, 'I8')
```

For 82213, the result is 19820801.
For 82004, the result is 19820104.

**YM: Calculating Elapsed Months**

The YM function calculates the number of months between two dates. The dates must be in year-month format. You can convert a date to this format by using the CHGDAT or EDIT function.

**Syntax:**  How to Calculate Elapsed Months

```
YM(fromdate, todate, output)
```

where:

- **fromdate**
  - I4YM or I6YYM
  - Is the start date in year-month format (for example, I4YM). If the date is not valid, the function returns the value 0 (zero).
todate

I4YM or I6YYM

Is the end date in year-month format. If the date is not valid, the function returns the value 0 (zero).

output

Integer

Tip: If fromdate or todate is in integer year-month-day format (I6YMD or I8YYMD), simply divide by 100 to convert to year-month format and set the result to an integer. This drops the day portion of the date, which is now after the decimal point.

Example: Calculating Elapsed Months

YM calculates the difference between HIRE_MONTH and MONTH_INC and stores the results in a column with the format I3.

YM(HIRE_MONTH, MONTH_INC, 'I3')
Date-Time functions are for use with timestamps in date-time formats, also known as H formats. A timestamp value refers to internally stored data capable of holding both date and time components with an accuracy of up to a nanosecond.

In this chapter:

- Using Date-Time Functions
- HADD: Incrementing a Date-Time Value
- HCNVRT: Converting a Date-Time Value to Alphanumeric Format
- HDATE: Converting the Date Portion of a Date-Time Value to a Date Format
- HDIFF: Finding the Number of Units Between Two Date-Time Values
- HDTTM: Converting a Date Value to a Date-Time Value
- HGETC: Storing the Current Local Date and Time in a Date-Time Field
- HGETZ: Storing the Current Coordinated Universal Time in a Date-Time Field
- HHMMSS: Retrieving the Current Time
- HHMS: Converting a Date-Time Value to a Time Value
- HINPUT: Converting an Alphanumeric String to a Date-Time Value
- HMMIDNT: Setting the Time Portion of a Date-Time Value to Midnight
- HNAME: Retrieving a Date-Time Component in Alphanumeric Format
- HPART: Retrieving a Date-Time Component as a Numeric Value
- HSETPT: Inserting a Component Into a Date-Time Value
- HTIME: Converting the Time Portion of a Date-Time Value to a Number
- HTMTOTS: Converting a Time to a Timestamp
- HYYWD: Returning the Year and Week Number From a Date-Time Value
Using Date-Time Functions

The functions described in this section operate on fields in date-time format (sometimes called H format).

However, you can also provide a date as a character string using the macro DT, followed by a character string in parentheses, presenting date and time. Date components are separated by slashes '/'; time components by colons ':%'.

Alternatively, the day can be given as a natural day, like 2004 March 31, in parentheses. Either the date or time component can be omitted. For example, the date-time format argument can be expressed as DT(2004/03/11 13:24:25.99) or DT(March 11 2004).

The following is another example that creates a timestamp representing the current date and time. The system variables &YYMD and &TOD are used to obtain the current date and time, respectively:

```
-SET &MYSTAMP = &YYMD | ' ' | EDIT(&TOD,'99:$99:$99');
```

Today’s date (&YYMD) is concatenated with the time of day (&TOD). The EDIT function is used to change the dots (.) in the time of day variable to colons (:).

The following request uses the DT macro on the alphanumeric date and time variable &MYSTAMP:

```
TABLE FILE CAR
   PRINT CAR NOPRINT
   COMPUTE   DTCUR/HYYMDS = DT(&MYSTAMP);
   IF RECORDLIMIT IS 1;
END
```

Date-Time Parameters

The DATEFORMAT parameter specifies the order of the date components for certain types of date-time values. The WEEKFIRST parameter specifies the first day of the week. The DTSTRICT parameter determines the extent to which date-time values are checked for validity.

Specifying the Order of Date Components

The DATEFORMAT parameter specifies the order of the date components (month/day/year) when date-time values are entered in the formatted string and translated string formats. It makes the input format of a value independent of the format of the variable to which it is being assigned.
Syntax: How to Specify the Order of Date Components in a Date-Time Field

SET DATEFORMAT = option

where:

option

Can be one of the following: MDY, DMY, YMD, or MYD. MDY is the default value for the U.S. English format.

Specifying the First Day of the Week for Use in Date-Time Functions

The WEEKFIRST parameter specifies a day of the week as the start of the week. This is used in week computations by the HADD, HDIFF, HNAME, HPART, and HYYWD functions. It is also used by the DTADD, DTDIFF, DTRUNC, and DTPART functions. The default values are different for these functions, as described in How to Set a Day as the Start of the Week on page 251.

The WEEKFIRST parameter does not change the day of the month that corresponds to each day of the week, but only specifies which day is considered the start of the week.

The HPART, DTPART, HYYWD, and HNAME subroutines can extract a week number from a date-time value. To determine a week number, they can use different definitions. For example, ISO 8601 standard week numbering defines the first week of the year as the first week in January with four or more days. Any preceding days in January belong to week 52 or 53 of the preceding year. The ISO standard also establishes Monday as the first day of the week.

You specify which type of week numbering to use by setting the WEEKFIRST parameter, as described in How to Set a Day as the Start of the Week on page 251.

Since the week number returned by HNAME, DTPART, and HPART functions can be in the current year or the year preceding or following, the week number by itself may not be useful. The function HYYWD returns both the year and the week for a given date-time value.

Syntax: How to Set a Day as the Start of the Week

SET WEEKFIRST = value

where:

value

Can be:

- 1 through 7, representing Sunday through Saturday with non-standard week numbering.
Week numbering using these values establishes the first week in January with seven
days as week number 1. Preceding days in January belong to the last week of the
previous year. All weeks have seven days.

- **ISO1 through ISO7**, representing Sunday through Saturday with ISO standard week
  numbering.

  **Note:** ISO is a synonym for ISO2.

  Week numbering using these values establishes the first week in January with at least
  four days as week number 1. Preceding days in January belong to the last week of the
  previous year. All weeks have seven days.

- **STD1 through STD7**, in which the digit 1 (Sunday) through 7 (Saturday) indicates the
  starting day of the week.

  **Note:** STD without a digit is equivalent to STD1.

  Week numbering using these values is as follows. Week number 1 begins on January 1
  and ends on the day preceding the first day of the week. For example, for STD1, the
  first week ends on the first Saturday of the year. The first and last week may have
  fewer than seven days.

- **SIMPLE**, which establishes January 1 as the start of week 1, January 8 is the start of
  week 2, and so on. The first day of the week is, thus, the same as the first day of the
  year. The last week (week 53) is either one or two days long.

- **0 (zero)**, is the value of the WEEKFIRST setting before the user issues an explicit
  WEEKFIRST setting. The date-time functions HPART, HNAME, HYWD, HADD, and HDIFF
  use Saturday as the start of the week, when the WEEKFIRST setting is 0. The simplified
  functions DTADD, DTDIFF, DTRUNC, and DTPART, as well as printing of dates truncated
  to weeks, and recognition of date constant strings that contain week numbers, use
  Sunday as the default value, when the WEEKFIRST setting is 0. If the user explicitly
  sets WEEKFIRST to another value, that value is used by all of the functions.

**Example:** Setting Sunday as the Start of the Week

The following designates Sunday as the start of the week, using non-standard week
numbering:

```
SET WEEKFIRST = 1
```
**Syntax:** How to View the Current Setting of WEEKFIRST

```
? SET WEEKFIRST
```

This returns the value that indicates the week numbering algorithm and the first day of the week. For example, the integer 1 represents Sunday with non-standard week numbering.

**Controlling Processing of Date-Time Values**

Strict processing checks date-time values when they are input by an end user, read from a transaction file, displayed, or returned by a subroutine to ensure that they represent a valid date and time. For example, a numeric month must be between 1 and 12, and the day must be within the number of days for the specified month.

**Syntax:** How to Enable Strict Processing of Date-Time Values

```
SET DTSTRICT = {ON|OFF}
```

where:

**ON**

Invokes strict processing. ON is the default value.

Strict processing checks date-time values when they are input by an end user, read from a transaction file, displayed, or returned by a subroutine to ensure that they represent a valid date and time. For example, a numeric month must be between 1 and 12, and the day must be within the number of days for the specified month.

If DTSTRICT is ON and the result would be an invalid date-time value, the function returns the value zero (0).

**OFF**

Does not invoke strict processing. Date-time components can have any value within the constraint of the number of decimal digits allowed in the field. For example, if the field is a two-digit month, the value can be 12 or 99, but not 115.

**Supplying Arguments for Date-Time Functions**

Date-time functions may operate on a component of a date-time value. This topic lists the valid component names and abbreviations for use with these functions.
Reference: Arguments for Use With Date and Time Functions

The following component names, valid abbreviations, and values are supported as arguments for the date-time functions that require them:

<table>
<thead>
<tr>
<th>Component Name</th>
<th>Abbreviation</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>yy</td>
<td>0001-9999</td>
</tr>
<tr>
<td>quarter</td>
<td>qq</td>
<td>1-4</td>
</tr>
<tr>
<td>month</td>
<td>mm</td>
<td>1-12 or a month name, depending on the function.</td>
</tr>
<tr>
<td>day-of-year</td>
<td>dy</td>
<td>1-366</td>
</tr>
<tr>
<td>day or day-of-month</td>
<td>dd</td>
<td>1-31 (The two component names are equivalent.)</td>
</tr>
<tr>
<td>week</td>
<td>wk</td>
<td>1-53</td>
</tr>
<tr>
<td>weekday</td>
<td>dw</td>
<td>1-7 (Sunday-Saturday)</td>
</tr>
<tr>
<td>hour</td>
<td>hh</td>
<td>0-23</td>
</tr>
<tr>
<td>minute</td>
<td>mi</td>
<td>0-59</td>
</tr>
<tr>
<td>second</td>
<td>ss</td>
<td>0-59</td>
</tr>
<tr>
<td>millisecond</td>
<td>ms</td>
<td>0-999</td>
</tr>
<tr>
<td>microsecond</td>
<td>mc</td>
<td>0-999999</td>
</tr>
<tr>
<td>nanosecond</td>
<td>ns</td>
<td>0-999999999</td>
</tr>
</tbody>
</table>

Note:

For an argument that specifies a length of eight, ten, or 12 characters, use eight to include milliseconds, ten to include microseconds, and 12 to include nanoseconds in the returned value.
The last argument is always a USAGE format that indicates the data type returned by the function. The type may be A (alphanumeric), I (integer), D (floating-point double precision), H (date-time), or a date format (for example, YYMD).

**HADD: Incrementing a Date-Time Value**

The HADD function increments a date-time value by a given number of units.

**Syntax:**

**How to Increment a Date-Time Value**

HADD(datetime, 'component', increment, length, output)

where:

datetime

Date-time

Is the date-time value to be incremented.

component

Alphanumeric

Is the name of the component to be incremented enclosed in single quotation marks. For a list of valid components, see *Arguments for Use With Date and Time Functions* on page 254.

Note: WEEKDAY is not a valid component for HADD.

increment

Integer

Is the number of units (positive or negative) by which to increment the component.

length

Integer

Is the number of characters returned. Valid values are:

- **8** indicates a date-time value that includes one to three decimal digits (milliseconds).
- **10** indicates a date-time value that includes four to six decimal digits (microseconds).
- **12** indicates a date-time value that includes seven to nine decimal digits (nanoseconds).
Example: Incrementing a Date-Time Value

The following example increments thirty months to some specific date-time in the past:

\[
\text{HADD(\textbf{DT}(2001/09/11 08:54:34), 'MONTH', 30, 8, 'HYYMDS')}\]

and returns the timestamp 2004/03/11 08:54:34.00.

Example: Converting Unix (Epoch) Time to a Date-Time Value

Unix time (also known as Epoch time) defines an instant in time as the number of seconds that have elapsed since 00:00:00 Coordinated Universal Time (UTC), Thursday, 1 January 1970, not counting leap seconds.

The following DEFINE FUNCTION takes a number representing epoch time and converts it to a date-time value by using the HADD function to add the number of seconds represented by the input value in epoch time to the epoch base date:

\[
\text{DEFINE FUNCTION UNIX2GMT(INPUT/I9)}
\]

\[
\text{UNIX2GMT/HYYMDS = HADD(DT(1970 JAN 1), 'SECONDS', INPUT, 8, 'HYYMDS');}
\]

The following request uses this DEFINE FUNCTION to convert the epoch time 1449068652 to a date-time value:

\[
\text{DEFINE FILE GGSALES}
\]

\[
\text{INPUT/I9=1449068652;}
\]

\[
\text{OUTDATE/HMTDYYSb = UNIX2GMT(INPUT);}\]

\[
\text{END}
\]

\[
\text{TABLE FILE GGSALES}
\]

\[
\text{PRINT DATE NOPRINT INPUT OUTDATE}
\]

\[
\text{WHERE RECORDLIMIT EQ 1}
\]

\[
\text{ON TABLE SET PAGE NOLEAD}
\]

\[
\text{END}
\]

The output is shown in the following image:

<table>
<thead>
<tr>
<th>INPUT</th>
<th>OUTDATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1449068652</td>
<td>December 02 2015 3:04:12 pm</td>
</tr>
</tbody>
</table>
HCNVRT: Converting a Date-Time Value to Alphanumeric Format

The HCNVRT function converts a date-time value to alphanumeric format for use with operators such as EDIT, CONTAINS, and LIKE.

Syntax: How to Convert a Date-Time Value to Alphanumeric Format

HCNVRT(datetime, '(format)', length, output)

where:

datetime
Date-time
Is the date-time value to be converted.

format
Alphanumeric
Is the format of the date-time field enclosed in parentheses and single quotation marks. It must be a date-time format (data type H, up to H23).

length
Integer
Is the number of characters in the alphanumeric field that is returned. If length is smaller than the number of characters needed to display the alphanumeric field, the function returns a blank.

output
Alphanumeric

Example: Converting a Date-Time Value to Alphanumeric Format

Assume that you have a date-time field DTCUR in H format. To convert this timestamp to an alphanumeric string, use the following syntax:

HCNVRT(DTCUR, '(HMDYYS)', 20, 'A20')

The function returns the string '03/26/2004 14:25:58' that is assignable to an alphanumeric variable.
HDATrE: Converting the Date Portion of a Date-Time Value to a Date Format

The HDATE function converts the date portion of a date-time value to the date format YYMD. You can then convert the result to other date formats.

Syntax:
HDATrE(datetime, output)

where:
datetime
   Date-time
   Is the date-time value to be converted.
output
   Date

Example:
Converting the Date Portion of a Timestamp Value to a Date Format
This example converts the DTCUR field, which is the current date/time timestamp, into a date field using the format DMY:
MYDATE/DMY = HDATE(DTCUR, 'YYMD');

The function returns the date in format YYMD, then assigns it to MYDATE after conversion to its format MY as 03/04. Note that the output_format of HDATE is presented as a full component date format MDYY, as required.

HDIFtr: Finding the Number of Units Between Two Date-Time Values

The HDIFtr function calculates the number of date or time component units between two date-time values.

Reference: Usage Notes for HDIFtr
HDIFtr does its subtraction differently from DATEDIF, which subtracts date components stored in date fields. The DATEDIF calculation looks for full years or full months. Therefore, subtracting the following two dates and requesting the number of months or years, results in 0:
DATE1 12/25/2014, DATE2 1/5/2015
Performing the same calculation using HDIFF on date-time fields results in a value of 1 month or 1 year as, in this case, the month or year is first extracted from each date-time value, and then the subtraction occurs.

**Syntax:**

How to Find the Number of Units Between Two Date-Time Values

\[
\text{HDIFF}(\text{end}_dt, \text{start}_dt, \text{'component'}, \text{output})
\]

where:

**end\_dt**
- Date-time
- Is the date-time value to subtract from.

**start\_dt**
- Date-time
- Is the date-time value to subtract.

**component**
- Alphanumeric
- Is the name of the component to be used in the calculation, enclosed in single quotation marks. If the component is a week, the WEEKFIRST parameter setting is used in the calculation.

**output**
- Floating-point double-precision

**Example:**

Finding the Number of Units Between Two Date-Time Values

Assume that we have a date-time field DTCUR in H format, which is has a current date and time timestamp. To find the number of days from President’s Day 2004 to today use the expression:

\[
\text{DIFDAY/I6} = \text{HDIF(DTCUR, DT(2004/02/16), \text{'DAY'}, \text{'D6.0'})}
\]

The function returns the number of days in double precision floating point format, then assigns it to DIFDAY as integer value. If today is March 31, 2004, the DIFDAY is assigned to 46.
If you wish to obtain results in seconds, use the expression

\[
\text{DIFSEC/}I9 = \text{HDIF(DTCUR, DT(2004 February 16), 'SECOND', 'D9.0')}
\]

which assigns 3801600 to DIFSEC. Note that the format 'D9.0' is used with HDIF. Using 'I9' for an output_format in HDIF is invalid.

**HDTTM: Converting a Date Value to a Date-Time Value**

The HDTTM function converts a date value to a date-time value. The time portion is set to midnight.

**Syntax:**

How to Convert a Date Value to a Date-Time Value

\[
\text{HDTTM}(date, length, output)
\]

where:

- **date**
  
  Date
  
  Is the date to be converted. It must be a full component format date. For example, it can be MDYY or YYJUL.

- **length**
  
  Integer
  
  Is the length of the returned date-time value. Valid values are:
  
  - 8 indicates a time value that includes milliseconds.
  - 10 indicates a time value that includes microseconds.
  - 12 indicates a time value that includes nanoseconds.

- **output**
  
  Date-time
  
  Is the generated date-time value. The value must have a date-time format (data type H).
Example: Converting a Date to a Timestamp

This example converts the President’s Day date into a timestamp:

\[ TS/\text{HYYMD} = \text{HDTTM}('\text{February 16 2004}', 8, TS) \]

the function returns 2004/02/16 00:00:00 and assigns this timestamp to field TS. Note the zero values of time components in the timestamp. Also note the use of natural date constants in single quotation marks for the date in the first function parameter.

HGETC: Storing the Current Local Date and Time in a Date-Time Field

The HGETC function returns the current local date and time in the desired date-time format. If millisecond or microsecond values are not available in your operating environment, the function retrieves the value zero for these components.

Syntax: How to Store the Current Local Date and Time in a Date-Time Field

\[ \text{HGETC}(\text{length}, \text{output}) \]

where:

- \text{length} 
  Integer
  Is the length of the returned date-time value. Valid values are:
  - \textbf{8} indicates a time value that includes milliseconds.
  - \textbf{10} indicates a time value that includes microseconds.
  - \textbf{12} indicates a time value that includes nanoseconds.

- \text{output} 
  Date-time
  Is the returned date-time value.

Example: Storing the Current Date and Time as a Timestamp

This example,

\[ \text{HGETC}(8, '\text{HYYMD}') \]

creates a timestamp representing the current date and time.
HGETZ: Storing the Current Coordinated Universal Time in a Date-Time Field

HGETZ provides the current Coordinated Universal Time (UTC/GMT time, often called Zulu time). UTC is the primary civil time standard by which the world regulates clocks and time.

The value is returned in the desired date-time format. If millisecond or microsecond values are not available in your operating environment, the function retrieves the value zero for these components.

Syntax: How to Store the Current Universal Date and Time in a Date-Time Field

\[ \text{HGETZ}(\text{length}, \text{output}) \]

where:

\textit{length}

Integer

Is the length of the returned date-time value. Valid values are:

- 8 indicates a time value that includes milliseconds.
- 10 indicates a time value that includes microseconds.
- 12 indicates a time value that includes nanoseconds.

\textit{output}

Date-time

Is the returned date-time value.

Example: Storing the Current Universal Date and Time as a Timestamp

This example,

\[ \text{HGETZ}(8, 'HYYMDS') \]

creates a timestamp representing the current date and time.
**Example:** Calculating the Time Zone

The time zone can be calculated as a positive or negative hourly offset from GMT. Locations to the west of the prime meridian have a negative offset. The following request uses the HGETC function to retrieve the local time, and the HGETZ function to retrieve the GMT time. The HDIFF function calculates the number of boundaries between them in minutes. The zone is found by dividing the minutes by 60:

```
DEFINE FILE EMPLOYEE
LOCALTIME/HYYMDS = HGETC(8, LOCALTIME);
UTCTIME/HYYMDS = HGETZ(8, UTCTIME);
MINUTES/D4= HDIFF(LOCALTIME, UTCTIME, 'MINUTES', 'D4');
ZONE/P3 = MINUTES/60;
END
```

```
TABLE FILE EMPLOYEE
PRINT EMP_ID NOPRINT OVER
LOCALTIME OVER
UTCTIME OVER
MINUTES OVER
ZONE
IF RECORDLIMIT IS 1
END
```

The output is:

```
LOCALTIME  2015/05/12 12:47:04
UTCTIME    2015/05/12 16:47:04
MINUTES                     -240
ZONE                        -4
```

**HHMMSS: Retrieving the Current Time**

The HHMMSS function retrieves the current time from the operating system as an eight character string, separating the hours, minutes, and seconds with periods.

**Syntax:** How to Retrieve the Current Time

```
HHMMSS(output)
```

where:

```
output
```

Alphanumeric, at least A8
**Example:** Retrieving the Current Time

This example,

```
HMMSS('A10')
```

creates a character string representing current time, like 12.09.47. Note that shorter output_format format will cause truncation of output.

**HHMS: Converting a Date-Time Value to a Time Value**

The HHMS function converts a date-time value to a time value.

**Syntax:** How to Convert a Date-Time Value to a Time Value

```
HHMS(datetime, length, output)
```

where:

- **datetime**
  - Date-time
  - Is the date-time value to be converted.

- **length**
  - Numeric
  - Is the length of the returned time value. Valid values are:
    - 8 indicates a time value that includes milliseconds.
    - 10 indicates a time value that includes microseconds.
    - 12 indicates a time value that includes nanoseconds.

- **output**
  - Time

**Example:** Converting a Date-Time Value to a Time value

HHMS converts the date-time field TRANSDATE to a time value with format HHIS:

```
HHMS(TRANSDATE, 8, 'HHIS')
```

For 2000/06/26 05:45, the output is 05:45:00
**HINPUT: Converting an Alphanumeric String to a Date-Time Value**

The HINPUT function converts an alphanumeric string to a date-time value.

**Syntax:**

**How to Convert an Alphanumeric String to a Date-Time Value**

\[
\text{HINPUT(} \text{source\_length, 'source\_string', output\_length, output) }
\]

where:

- **source\_length**
  - Integer
  - Is the number of characters in the source string to be converted.

- **source\_string**
  - Alphanumeric
  - Is the string to be converted.

- **output\_length**
  - Integer
  - Is the length of the returned date-time value. Valid values are:
    - 8 indicates a time value that includes one to three decimal digits (milliseconds).
    - 10 indicates a time value that includes four to six decimal digits (microseconds).
    - 12 indicates a time value that includes seven to nine decimal digits (nanoseconds).

- **output**
  - Date-time
  - Is the returned date-time value.

**Example:** **Converting an Alphanumeric String to a Timestamp**

This example,

\[
\text{DTM/YYMDS = HINPUT(14, '20040229 13:34:00', 8, DTM);} 
\]

converts the character string (20040229 13:34:00) into a timestamp, which is then assigned to the date-time field DTM. DTM is displayed as 2004/02/29 13:34:00.
**HMIDNT: Setting the Time Portion of a Date-Time Value to Midnight**

The HMIDNT function changes the time portion of a date-time value to midnight (all zeros by default). This allows you to compare a date field with a date-time field.

**Syntax:**

**How to Set the Time Portion of a Date-Time Value to Midnight**

```plaintext
HMIDNT(datetime, length, output)
```

*where:*

- **datetime**
  
  Date-time
  
  Is the date-time value whose time is to be set to midnight.

- **length**
  
  Integer
  
  Is the length of the returned date-time value. Valid values are:
  
  - **8** indicates a time value that includes milliseconds.
  - **10** indicates a time value that includes microseconds.
  - **12** indicates a time value that includes nanoseconds.

- **output**
  
  Date-time
  
  Is the date-time return value whose time is set to midnight and whose date is copied from timestamp.

**Example:**

**Setting the Time Portion of a Timestamp to Midnight**

This example converts the character string (20040229 13:34:00) to a timestamp, which is assigned to DTM:

```plaintext
DTM/HYYMDS = HINPUT(14, '20040229 13:34:00', 8, DTM);
```

This example resets the time portion of DTM to midnight and assigned the timestamp (02/29/2004 00:00:00) to DTMDNT:

```plaintext
DTMDNT/HMDYYS = HMIDNT(DTM, 8, DTMDNT);
```
HNAME: Retrieving a Date-Time Component in Alphanumeric Format

The HNAME function extracts a specified component from a date-time value and returns it in alphanumeric format.

Syntax: How to Retrieve a Date-Time Component in Alphanumeric Format

\[
\text{HNAME}(\text{datetime}, \text{component}, \text{output})
\]

where:

- \text{datetime}
  - Date-time
  - Is the date-time value from which a component value is to be extracted.

- \text{component}
  - Alphanumeric
  - Is the name of the component to be retrieved enclosed in single quotation marks. For a list of valid components, see Arguments for Use With Date and Time Functions on page 254.

- \text{output}
  - Alphanumeric, at least \text{A2}
  - The function converts a month argument to an abbreviation of the month name and converts all other components to strings of digits only. The year is always four digits, and the hour assumes the 24-hour system.

Example: Retrieving a Timestamp Date or Time Component as an Alphanumeric Value

Assuming that the current time obtained by the function HGETC in the first parameter is 13:22:11, this example returns the string '13' and assigns it to AHOUR:

\[
\text{AHOUR/A2} = \text{HNAME(\text{HGETC}(8, \text{HYYMDS}), \text{HOUR}, \text{AHOUR});}
\]

Example: Retrieving a Timestamp Date or Time Component as an Alphanumeric Value

Assuming that the current time obtained by the function HGETC in the first parameter is 13:22:11, this example returns the string '13' and assigns it to AHOUR:

\[
\text{AHOUR/A2} = \text{HNAME(\text{HGETC}(8, \text{HYYMDS}), \text{HOUR}, \text{AHOUR});}
\]

HPART: Retrieving a Date-Time Component as a Numeric Value

The HPART function extracts a specified component from a date-time value and returns it in numeric format.
Syntax: How to Retrieve a Date-Time Component in Numeric Format

```lisp
HPART(datetime, 'component', output)
```

where:
- `datetime`
  
  Date-time
  
  Is the date-time value from which the component is to be extracted.
- `component`
  
  Alphanumeric
  
  Is the name of the component to be retrieved enclosed in single quotation marks. For a list of valid components, see Arguments for Use With Date and Time Functions on page 254.
- `output`
  
  Integer

Example: Retrieving a Timestamp Date or Time Component as Numeric Value

Assuming that the current time obtained by HGETC in the first parameter is 14:01:39, this example returns a whole number, 14, and assigns it to IHOUR:

```lisp
IHOUR/I2 = HPART(HGETC(8,'HYMDS'),'HOUR', IHOUR);
```

HSETPT: Inserting a Component Into a Date-Time Value

The HSETPT function inserts the numeric value of a specified component into a date-time value.

Syntax: How to Insert a Component Into a Date-Time Value

```lisp
HSETPT(datetime, 'component', value, length, output)
```

where:
- `datetime`
  
  Date-time
  
  Is the date-time value in which to insert the component.
component

Alphanumeric

Is the name of the component to be inserted enclosed in single quotation marks. See "Arguments for Use With Date and Time Functions" on page 254 for a list of valid components.

value

Integer

Is the numeric value to be inserted for the requested component.

length

Integer

Is the length of the returned date-time value. Valid values are:

- **8** indicates a time value that includes one to three decimal digits (milliseconds).
- **10** indicates a time value that includes four to six decimal digits (microseconds).
- **12** indicates a time value that includes seven to nine decimal digits (nanoseconds).

output

Date-time

Is the returned date-time value whose chosen component is updated. All other components are copied from the source date-time value.

**Example:** Inserting a Component Into a Date-Time Value

Assuming that the current date and time obtained by HGETC in the first parameter are 03/31/2004 and 13:34:36, this example,

\[
\text{UHOUR/HMDYYS = HSETPT(HGETC(8, 'HYYMDS'), 'HOUR', 7, 8, UHOUR);}\]

returns 03/31/2004 07:34:36.

**HTIME: Converting the Time Portion of a Date-Time Value to a Number**

The HTIME function converts the time portion of a date-time value to the number of milliseconds if the length argument is eight, microseconds if the length argument is ten, or nanoseconds if the length argument is 12.
Syntax: How to Convert the Time Portion of a Date-Time Value to a Number

HTIME(length, datetime, output)

where:

length

Integer
Is the length of the input date-time value. Valid values are:

- 8 indicates a time value that includes one to three decimal digits (milliseconds).
- 10 indicates a time value that includes four to six decimal digits (microseconds).
- 12 indicates a time value that includes seven to nine decimal digits (nanoseconds).

datetime

Date-time
Is the date-time value from which to convert the time.

output

Floating-point double-precision

Example: Converting the Time Portion of a Date-Time Value to a Number

Assuming that the current date and time obtained by HGETC in the second parameter are 03/31/2004 and 13:48:14, this example returns and assigns to NMILLI, 49,694,395. (Note that this example uses milliseconds rather than microseconds.)

NMILLI/D12.0 = HTIME(8, HGETC(10,'HYYMDS'), NMICRO);

Assuming that the first parameter is equal to 10 and the timestamp format is HYYMDSS, this example returns and assigns to NMICRO, 50,686,123,024.

NMICRO/D12.0 = HTIME(10, HGETC(10,'HYYMDSS'), NMICRO);

HTMTOTS: Converting a Time to a Timestamp

The HTMTOTS function returns a timestamp using the current date to supply the date components of its value, and copies the time components from its input date-time value.

Syntax: How to Convert a Time to a Timestamp

HTMTOTS(time, length, output)
where:

**time**

Date-Time

Is the date-time value whose time will be used. The date portion will be ignored.

**length**

Integer

Is the length of the result. This can be one of the following:

- **8** for input time values including milliseconds.
- **10** for input time values including microseconds.
- **12** for input time values including nanoseconds.

**output_format**

Date-Time

Is the timestamp whose date is set to the current date, and whose time is copied from time.

**Example:**  Converting a Time to a Timestamp

This example produces a timestamp, whose date and time are current, and stores the result in a column with the format in the field HMDYYS:

```sql
HMDYYS = HTMTOTS(DT(&MYTOD), 8, 'HMDYYS');
```

**HYYWD: Returning the Year and Week Number From a Date-Time Value**

The week number returned by HNAME and HPART can actually be in the year preceding or following the input date.

The HYYWD function returns both the year and the week number from a given date-time value.

The output is edited to conform to the ISO standard format for dates with week numbers, yyyy-Www-d.
Syntax: How to Return the Year and Week Number From a Date-Time Value

\[ \text{HYYWD}(\text{dtvalue}, \text{output}) \]

where:

\textit{dtvalue}

Date-time

Is the date-time value to be edited.

\textit{output}

Alphanumeric

The output format must be at least 10 characters long. The output is in the following format:

\[ \text{yyyy-Www-d} \]

where:

\textit{yyyy}

Is the four-digit year.

\textit{ww}

Is the two-digit week number (01 to 53).

\textit{d}

Is the single-digit day of the week (1 to 7). The \textit{d} value is relative to the current \textsc{weekfirst} setting. If \textsc{weekfirst} is 2 or ISO2 (Monday), then Monday is represented in the output as 1, Tuesday as 2.

Using the \textsc{edit} function, you can extract the individual subfields from this output.

Example: Returning the Year and Week Number From a Date-time Value

The following converts the \textsc{transdate} date-time value to the ISO standard format for dates with week numbers. \textsc{weekfirst} is set to \textsc{iso2}, which produces ISO standard week numbering:

\[ \text{ISODATE/A10} = \text{HYYWD(TRANSDATE, } \text{'A10'}) ; \]

For date component 1999/01/30 04:16, the value is 1999-W04-6.
For date component 1999/12/15, the value is 1999-W50-3.
Simplified Conversion Functions

Simplified conversion functions have streamlined parameter lists, similar to those used by SQL functions. In some cases, these simplified functions provide slightly different functionality than previous versions of similar functions.

The simplified functions do not have an output argument. Each function returns a value that has a specific data type.

When used in a request against a relational data source, these functions are optimized (passed to the RDBMS for processing).

In this chapter:

- CHAR: Returning a Character Based on a Numeric Code
- COMPACTFORMAT: Displaying Numbers in an Abbreviated Format
- CTRLCHAR: Returning a Non-Printable Control Character
- FPRINT: Displaying a Value in a Specified Format
- HEXTYPE: Returning the Hexadecimal View of an Input Value
- PHONETIC: Returning a Phonetic Key for a String
- TO_INTEGER: Converting a Character String to an Integer Value
- TO_NUMBER: Converting a Character String to a Numeric Value

CHAR: Returning a Character Based on a Numeric Code

The CHAR function accepts a decimal integer and returns the character identified by that number converted to ASCII or EBCDIC, depending on the operating environment. The output is returned as variable length alphanumeric. If the number is above the range of valid characters, a null value is returned.

For a chart of printable characters and their decimal equivalents, see Character Chart for ASCII and EBCDIC.

Syntax: How to Return a Character Based on a Numeric Code

`CHAR(number_code)`
where:

\textit{number\_code} \\
\textit{Integer} \\

Is a field, number, or numeric expression whose whole absolute value will be used as a number code to retrieve an output character.

For example, a TAB character is returned by \texttt{CHAR(9)} in ASCII environments, or by \texttt{CHAR(5)} in EBCDIC environments.

\textbf{Example: Using the CHAR Function to Insert Control Characters Into a String}

\texttt{CHAR} returns a carriage control character in an ASCII environment.

\texttt{CHAR(13)}

\textbf{COMPACTFORMAT: Displaying Numbers in an Abbreviated Format}

COMPACTFORMAT displays numbers in a compact format where:

- K is an abbreviation for thousands.
- M is an abbreviation for millions.
- B is an abbreviation for billions.
- T is an abbreviation for trillions.

COMPACTFORMAT computes which abbreviation to use, based on the order of magnitude of the largest value in the column. The returned value is an alphanumeric string. Attempting to output this value to a numeric format will result in a format error, and the value zero (0) will be displayed.

\textbf{Syntax: How to Display Numbers in an Abbreviated Format}

\texttt{COMPACTFORMAT(input)}

where:

\textit{input} \\
Is the name of a numeric field.

\textbf{Example: Displaying Numbers in an Abbreviated Format}

COMPACTFORMAT abbreviates the display of \texttt{COGS\_US}.

\texttt{COMPACTFORMAT(COGS\_US)}
For $2,950,358.00, the result is $3M.

**CTRLCHAR: Returning a Non-Printable Control Character**

The CTRLCHAR function returns a nonprintable control character specific to the running operating environment, based on a supported list of keywords. The output is returned as variable length alphanumeric.

**Syntax:** How to Return a Non-Printable Control Character

```plaintext
CTRLCHAR(ctrl_char)
```

where:

- `ctrl_char` is one of the following keywords.
  - **NUL** returns a null character.
  - **SOH** returns a start of heading character.
  - **STX** returns a start of text character.
  - **ETX** returns an end of text character.
  - **EOT** returns an end of transmission character.
  - **ENQ** returns an enquiry character.
  - **ACK** returns an acknowledge character.
  - **BEL** returns a bell or beep character.
  - **BS** returns a backspace character.
  - **TAB** or **HT** returns a horizontal tab character.
  - **LF** returns a line feed character.
  - **VT** returns a vertical tab character.
  - **FF** returns a form feed (top of page) character.
  - **CR** returns a carriage control character.
  - **SO** returns a shift out character.
  - **SI** returns a shift in character.
DLE returns a data link escape character.

DC1 or XON returns a device control 1 character.

DC2 returns a device control 2 character.

DC3 or XOFF returns a device control 3 character.

DC4 returns a device control 4 character.

NAK returns a negative acknowledge character.

SYN returns a synchronous idle character.

ETB returns an end of transmission block character.

CAN returns a cancel character.

EM returns an end of medium character.

SUB returns a substitute character.

ESC returns an escape, prefix, or altmode character.

FS returns a file separator character.

GS returns a group separator character.

RS returns a record separator character.

US returns a unit separator character.

DEL returns a delete, rubout, or interrupt character.

**Example:** Using the CTRLCHAR Function to Insert Control Characters Into a String

CTRLCHAR returns a carriage control character in an ASCII environment.

**CTRLCHAR (CR)**

**FPRINT: Displaying a Value in a Specified Format**

Given an output format, the simplified conversion function FPRINT converts a value to alphanumeric format for display.

**Note:** A legacy FPRINT function also exists and is still supported. For information, see *FPRINT: Converting Fields to Alphanumeric Format* on page 283. The legacy function has an additional argument for the name or format of the returned value.
Syntax: How to Display a Value in a Specified Format

FPRINT(value, 'out_format')

where:

value
Any data type
Is the value to be converted.

'out_format'
Fixed length alphanumeric
Is the display format. For information about valid display formats, see the manual.

Example: Displaying a Value in a Specified Format

FPRINT converts a date to alphanumeric format.

FPRINT(TIME_DATE, 'YYMtrD')

For 01/03/2009, the result is 2009, January 3.

HEXTYPE: Returning the Hexadecimal View of an Input Value

The HEXTYPE function returns the hexadecimal view of an input value of any data type. The result is returned as variable length alphanumeric. The alphanumeric field to which the hexadecimal value is returned must be large enough to hold two characters for each input character. The value returned depends on the running operating environment.

Syntax: How to Returning the Hexadecimal View of an Input Value

HEXTYPE(in_value)

where:

in_value
Is an alphanumeric or integer field, constant, or expression.

Example: Returning a Hexadecimal View

HEXTYPE returns a hexadecimal view of COUNTRY_NAME.

HEXTYPE(COUNTRY_NAME)

For Argentina, the result is 417267656E74696E61.
PHONETIC: Returning a Phonetic Key for a String

PHONETIC calculates a phonetic key for a string, or a null value on failure. Phonetic keys are useful for grouping alphanumeric values, such as names, that may have spelling variations. This is done by generating an index number that will be the same for the variations of the same name based on pronunciation. One of two phonetic algorithms can be used for indexing, Metaphone and Soundex. Metaphone is the default algorithm, except on z/OS where the default is Soundex.

You can set the algorithm to use with the following command.

```
SET PHONETIC_ALGORITHM = {METAPHONE|SOUNDEX}
```

Most phonetic algorithms were developed for use with the English language. Therefore, applying the rules to words in other languages may not give a meaningful result.

Metaphone is suitable for use with most English words, not just names. Metaphone algorithms are the basis for many popular spell checkers.

**Note:** Metaphone is not optimized in generated SQL. Therefore, if you need to optimize the request for an SQL DBMS, the SOUNDEX setting should be used.

Soundex is a legacy phonetic algorithm for indexing names by sound, as pronounced in English.

**Syntax:**

How to Return a Phonetic Key

```
PHONETIC(string)
```

where:

```
string
  Alphanumeric
```

Is a string for which to create the key. A null value will be returned on failure.

**Example:**

Generating a Phonetic Key

PHONETIC generates a phonetic key for LAST_NAME:

```
PHONETIC(LAST_NAME)
```

For last names SMITH and SMYTHE, the same phonetic key, S530, is generated.
TO_INTEGER: Converting a Character String to an Integer Value

TO_INTEGER converts a character string that contains a valid number consisting of digits and an optional decimal point to an integer value. If the value contains a decimal point, the value after the decimal point is truncated. If the value does not represent a valid number, zero (0) is returned.

Syntax: How to Convert a Character String to an Integer

```
TO_INTEGER(string)
```

where:

```
string
```

Is a character string enclosed in single quotation marks or a character field that represents a number containing digits and an optional decimal point.

Example: Converting a Character String to an Integer Value

TO_INTEGER converts the character string '56.78' to an integer.

```
TO_INTEGER('56.78')
```

The result is 56.

TO_NUMBER: Converting a Character String to a Numeric Value

TO_NUMBER converts a character string that contains a valid number consisting of digits and an optional decimal point to the numeric format most appropriate to the context. If the value does not represent a valid number, zero (0) is returned.

Syntax: How to Convert a Character String to a Number

```
TO_NUMBER(string)
```

where:

```
string
```

Is a character string enclosed in single quotation marks or a character field that represents a number containing digits and an optional decimal point. This string will be converted to a double-precision floating point number.

Example: Converting a Character String to a Number

TO_NUMBER converts the string '56.78' to a number with one decimal place.

```
TO_NUMBER('56.78')
```
The result is 56.8.
Format conversion functions convert fields from one format to another.

In this chapter:

- ATODBL: Converting an Alphanumeric String to Double-Precision Format
- EDIT: Converting the Format of a Field
- FPRINT: Converting Fields to Alphanumeric Format
- FTOA: Converting a Number to Alphanumeric Format
- HEXBYT: Converting a Decimal Integer to a Character
- ITONUM: Converting a Large Number to Double-Precision Format
- ITOPACK: Converting a Large Binary Integer to Packed-Decimal Format
- ITOZ: Converting a Number to Zoned Format
- PCKOUT: Writing a Packed Number of Variable Length
- PTOA: Converting a Packed-Decimal Number to Alphanumeric Format
- TSTOPACK: Converting an MSSQL or Sybase Timestamp Column to Packed Decimal
- UFMT: Converting an Alphanumeric String to Hexadecimal
- XTPACK: Writing a Packed Number With Up to 31 Significant Digits to an Output File

**ATODBL: Converting an Alphanumeric String to Double-Precision Format**

The ATODBL function converts a number in alphanumeric format to decimal (double-precision) format.

**Syntax:**

How to Convert an Alphanumeric String to Double-Precision Format

\[
\text{ATODBL}(\text{source_string, length, output})
\]

where:

- \(source\_\text{string}\)
  - Alphanumeric
Is the string consisting of digits and, optionally, one sign and one decimal point to be converted.

**length**
Alphanumeric
Is the length of the source string in bytes. This can be a numeric constant, or a field or variable that contains the value. If you specify a numeric constant, enclose it in single quotation marks, for example '12'.

**output**
Double precision floating-point

**Example:** Converting an Alphanumeric Field to Double-Precision Format

ATODBL converts EMP_ID into double-precision format.

`ATODBL(EMP_ID, '09', 'D12.2')`

For 112847612, the result is 112,847,612.00.

For 117593129, the result is 117,593,129.00.

**EDIT: Converting the Format of a Field**

The EDIT function converts an alphanumeric field that contains numeric characters to numeric format or converts a numeric field to alphanumeric format.

This function is useful for manipulating a field in an expression that performs an operation that requires operands in a particular format.

When EDIT assigns a converted value to a new field, the format of the new field must correspond to the format of the returned value. For example, if EDIT converts a numeric field to alphanumeric format, you must give the new field an alphanumeric format:

`DEFINE ALPHAPRICE/A6 = EDIT(PRICE);`

EDIT deals with a symbol in the following way:

- When an alphanumeric field is converted to numeric format, a sign or decimal point in the field is stored as part of the numeric value.
  
  Any other non-numeric characters are invalid, and EDIT returns the value zero.

- When converting a floating-point or packed-decimal field to alphanumeric format, EDIT removes the sign, the decimal point, and any number to the right of the decimal point. It then right-justifies the remaining digits and adds leading zeros to achieve the specified field length. Converting a number with more than nine significant digits in floating-point or packed-decimal format may produce an incorrect result.
EDIT also extracts characters from or add characters to an alphanumeric string. For more information, see *EDIT: Extracting or Adding Characters* on page 114.

**Syntax:**  
**How to Convert the Format of a Field**

```
EDIT(fieldname);
```

where:

- **fieldname**
  - Alphanumeric or Numeric
  - Is the field name.

**Example:**  
**Converting From Numeric to Alphanumeric Format**

EDIT converts HIRE_DATE (a legacy date format) to alphanumeric format.

```
EDIT(HIRE_DATE)
```

For 82/04/01, the result is 820401.

For 81/11/02, the result is 811102.

**FPRINT: Converting Fields to Alphanumeric Format**

The FPRINT function converts any type of field except for a text field to its alphanumeric equivalent for display. The alphanumeric representation will include any display options that are specified in the format of the original field.

**Syntax:**  
**How to Convert Fields Using FPRINT**

```
FPRINT(in_value, 'usageformat', output)
```

where:

- **in_value**
  - Any format except TX
  - Is the value to be converted.

- **usageformat**
  - Alphanumeric
  - Is the usage format of the value to be converted, including display options. The format must be enclosed in single quotation marks.
output

Alphanumeric

The output format must be long enough to hold the converted number itself, with a sign and decimal point, plus any additional characters generated by display options, such as commas, a currency symbol, or a percent sign.

For example, D12.2 format is converted to A14 because it outputs two decimal digits, a decimal point, a possible minus sign, up to eight integer digits, and two commas. If the output format is not large enough, excess right-hand characters may be truncated.

Reference: Usage Notes for the FPRINT Function

- The USAGE format must match the actual data in the field.
- The output of FPRINT for numeric values is right-justified within the area required for the maximum number of characters corresponding to the supplied format. This ensures that all possible values are aligned vertically along the decimal point or units digit.

Example: Converting a Numeric Field to Alphanumeric Format

FPRINT converts CURR_SAL (format D12.2)M to a column with format A15:

FPRINT(CURR_SAL, 'D12.2M', 'A15')

FTOA: Converting a Number to Alphanumeric Format

The FTOA function converts a number up to 16 digits long from numeric format to alphanumeric format. It retains the decimal positions of the number and right-justifies it with leading spaces.

You can also add edit options to a number converted by FTOA.

When using FTOA to convert a number containing decimals to a character string, you must specify an alphanumeric format large enough to accommodate both the integer and decimal portions of the number. For example, a D12.2 format is converted to A14. If the output format is not large enough, decimals are truncated.

Syntax: How to Convert a Number to Alphanumeric Format

FTOA(number, '(format)', output)

where:

number

Numeric F or D (single and double precision floating-point)

Is the number to be converted.
format
Alphanumeric

Is the format of the number to be converted enclosed in parentheses. Only floating point single-precision and double-precision formats are supported. Include any edit options that you want to appear in the output. The D (floating-point double-precision) format automatically supplies commas.

output
Alphanumeric

The length of this argument must be greater than the length of number and must account for edit options and a possible negative sign.

Example: Converting From Numeric to Alphanumeric Format
FTOA converts GROSS from floating point double-precision to alphanumeric format.

FTOA(GROSS, '©(D12.2)©, ©A15©)

For $1,815.00, the result is 1,815.00.
For $2,255.00, the result is 2,255.00.

HEXBYT: Converting a Decimal Integer to a Character

The HEXBYT function obtains the ASCII, EBCDIC, or Unicode character equivalent of a decimal integer, depending on your configuration and operating environment. The decimal value you specify must be the value associated with the character on the configured code page. HEXBYT returns a single alphanumeric character in the ASCII, EBCDIC, or Unicode character set. You can use this function to produce characters that are not on your keyboard, similar to the CTRAN function.

In Unicode configurations, this function uses values in the range:

- 0 to 255 for 1-byte characters.
- 256 to 65535 for 2-byte characters.
- 65536 to 16777215 for 3-byte characters.
- 16777216 to 4294967295 for 4-byte characters (primarily for EBCDIC).

The display of special characters depends on your software and hardware; not all special characters may appear.
Syntax: How to Convert a Decimal Integer to a Character

HEXBYT(decimal_value, output)

where:

decimal_value

Integer

Is the decimal integer to be converted to a single character. In non-Unicode environments, a value greater than 255 is treated as the remainder of decimal_value divided by 256. The decimal value you specify must be the value associated with the character on the configured code page.

output

Alphanumeric

Example: Converting a Decimal Integer to a Character in ASCII and Unicode

The following request uses HEXBYT to convert the decimal integer value 130 to the comma character on ASCII code page 1252. The comma is then concatenated between LAST_NAME and FIRST_NAME to create the NAME field:

TABLE FILE EMPLOYEE
PRINT LAST_NAME AND
COMPUTE COMMA1/A1 = HEXBYT(130, COMMA1); NOPRINT
COMPUTE NAME/A40 = LAST_NAME || COMMA1 | ' ' | FIRST_NAME;
BY LAST_NAME NOPRINT
BY FIRST_NAME
WHERE DEPARTMENT EQ 'MIS';
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
GRID=OFF,$
ENDSTYLE
END

The output is shown in the following image.

<table>
<thead>
<tr>
<th>FIRST_NAME</th>
<th>LAST_NAME</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROSEMARIE</td>
<td>BLACKWOOD</td>
<td>BLACKWOOD, ROSEMARIE</td>
</tr>
<tr>
<td>BARBARA</td>
<td>CROSS</td>
<td>CROSS, BARBARA</td>
</tr>
<tr>
<td>MARY</td>
<td>GREENSPAN</td>
<td>GREENSPAN, MARY</td>
</tr>
<tr>
<td>DIANE</td>
<td>JONES</td>
<td>JONES, DIANE</td>
</tr>
<tr>
<td>JOHN</td>
<td>MCCOY</td>
<td>MCCOY, JOHN</td>
</tr>
<tr>
<td>MARY</td>
<td>SMITH</td>
<td>SMITH, MARY</td>
</tr>
</tbody>
</table>
To produce the same output in a Unicode environment configured for code page 65001, replace the COMPUTE command for the field COMMA1 with the following syntax, in which the call to HEXBYT converts the integer value 14844058 to the comma character:

```
COMPUTE COMMA1/A1 = HEXBYT(14844058, COMMA1); NOPRINT
```

**Example: Converting a Decimal Integer to a Character**

HEXBYT converts LAST_INIT_CODE to its character equivalent and stores the result in a column with the format A1.

```
HEXBYT(LAST_INIT_CODE, 'A1')
```

On an ASCII platform, for 83, the result is S.
On ASCII platform, for 74, the result is J.

**ITONUM: Converting a Large Number to Double-Precision Format**

The ITONUM function converts a large number in a non-FOCUS data source from special long integer to double-precision format.

This is useful for some programming languages and some non-FOCUS data storage systems that use special long integers, which do not fit the regular integer format (four bytes in length) supported in the synonym, and, therefore, require conversion to double-precision format.

You must specify how many of the right-most bytes in the input field are significant. The result is an 8-byte double-precision field.

**Syntax: How to Convert a Large Binary Integer to Double-Precision Format**

```
ITONUM(maxbytes, infield, output)
```

where:

**maxbytes**

Numeric

Is the maximum number of bytes in the 8-byte binary input field that have significant numeric data, including the binary sign. Valid values are:

- 5 ignores the left-most 3 bytes.
- 6 ignores the left-most 2 bytes.
- 7 ignores the left-most byte.
infield

A8

Is the field that contains the number. Both the USAGE and ACTUAL formats of the field must be A8.

output

Double precision floating-point (Dn)

Example: Converting a Large Binary Integer to Double-Precision Format

ITONUM converts BINARYFLD to double-precision format.

ITONUM(6, BINARYFLD, 'D14')

ITOPACK: Converting a Large Binary Integer to Packed-Decimal Format

The ITOPACK function converts a large binary integer in a non-FOCUS data source to packed-decimal format.

This is useful for some programming languages and some non-FOCUS data storage systems that use special long integers, which do not fit the regular integer format (four bytes in length) supported in the synonym, and, therefore, require conversion to packed-decimal format.

You must specify how many of the right-most bytes in the input field are significant. The result is an 8-byte packed-decimal field of up to 15 significant numeric positions (for example, P15 or P16.2).

Limit: For a field defined as 'PIC 9(15) COMP' or the equivalent (15 significant digits), the maximum number that can be converted is 167,744,242,712,576.

Syntax: How to Convert a Large Binary Integer to Packed-Decimal Format

ITOPACK(maxbytes, infield, output)

where:

maxbytes

Numeric

Is the maximum number of bytes in the 8-byte input field that have significant numeric data, including the binary sign.

Valid values are:

- 5 ignores the left-most 3 bytes (up to 11 significant positions).
6 ignores the left-most 2 bytes (up to 14 significant positions).

7 ignores the left-most byte (up to 15 significant positions).

\textit{infield}

A8

Is the field that contains the binary number. Both the USAGE and ACTUAL formats of the field must be A8.

\textit{output}

Numeric

The format must be Pn or Pn.d.

\textbf{Example:} Converting a Large Binary Integer to Packed-Decimal Format

ITOPACK converts BINARYFLD to packed-decimal format.

\texttt{ITOPACK(6, BINARYFLD, 'P14.4')} \\

\textbf{ITOZ: Converting a Number to Zoned Format}

The ITOZ function converts a number in numeric format to zoned-decimal format. Although a request cannot process zoned numbers, it can write zoned fields to an extract file for use by an external program.

\textbf{Syntax:} How to Convert a Number to Zoned Format

\texttt{ITOZ(length, in\_value, output)}

where:

\textit{length}

Integer

Is the length of \textit{in\_value} in bytes. The maximum number of bytes is 15. The last byte includes the sign.

\textit{in\_value}

Numeric

Is the number to be converted. The number is truncated to an integer before it is converted.
**Example:** Converting a Number to Zoned Format

ITOZ converts CURR_SAL to zoned format.

\[
\text{ITOZ}(8, \text{CURR\_SAL}, 'A8')
\]

**PCKOUT: Writing a Packed Number of Variable Length**

The PCKOUT function writes a packed-decimal number of variable length to an extract file. When a request saves a packed number to an extract file, it typically writes it as an 8- or 16-byte field regardless of its format specification. With PCKOUT, you can vary the field's length between 1 to 16 bytes.

**Syntax:** How to Write a Packed Number of Variable Length

\[
PCKOUT(\text{in\_value}, \text{length}, \text{output})
\]

where:

- **in\_value**
  - Numeric
  - Is the input value. It can be in packed, integer, single- or double-precision floating point format. If it is not in integer format, it is rounded to the nearest whole number.

- **length**
  - Numeric
  - Is the length of the output value, from 1 to 16 bytes.

- **output**
  - Alphanumeric
  - The function returns the field as alphanumeric although it contains packed data.

**Example:** Writing a Packed Number of Variable Length

PCKOUT converts CURR_SAL to a five-byte packed format.

\[
PCKOUT(\text{CURR\_SAL}, 5, 'A5')
\]
PTOA: Converting a Packed-Decimal Number to Alphanumeric Format

The PTOA function converts a number from numeric format to alphanumeric format. It retains the decimal positions of the number and right-justifies it with leading spaces. You can also add edit options to a number converted by PTOA.

When using PTOA to convert a number containing decimals to a character string, you must specify an alphanumeric format large enough to accommodate both the integer and decimal portions of the number. For example, a P12.2C format is converted to A14. If the output format is not large enough, the right-most characters are truncated.

Syntax: How to Convert a Packed-Decimal Number to Alphanumeric Format

PTOA(number, '(format)', output)

where:
number
Numeric P (packed-decimal) or F or D (single and double precision floating-point)
Is the number to be converted.

format
Alphanumeric
Is the format of the number enclosed in parentheses.

output
Alphanumeric
The length of this argument must be greater than the length of number and must account for edit options and a possible negative sign.

Example: Converting From Packed to Alphanumeric Format

PTOA converts PGROSS from packed-decimal to alphanumeric format.

PTOA(PGROSS, FMT, 'A17')

TSTOPACK: Converting an MSSQL or Sybase Timestamp Column to Packed Decimal

This function applies to the Microsoft SQL Server and Sybase adapters only.
Microsoft SQL Server and Sybase have a data type called TIMESTAMP. Rather than containing an actual timestamp, columns with this data type contain a number that is incremented for each record inserted or updated in the data source. This timestamp comes from a common area, so no two tables in the database have the same timestamp column value. The value is stored in Binary(8) or Varbinary(8) format in the table, but is returned as a double wide alphanumeric column (A16). You can use the TSTOPACK function to convert the timestamp value to packed decimal.

**Syntax:**

**How to Convert an MSSQL or Sybase Timestamp Column to Packed Decimal**

```
TSTOPACK(tscol, output);
```

where:

* `tscol` A16
  
  Is the timestamp column to be converted.

* `output` P21

**Example:**

**Converting a Microsoft SQL Server Timestamp Column to Packed Decimal**

The Master File for the TSTEST data source follows. The field TS represents the TIMESTAMP column:

```
FILENAME=TSTEST, SUFFIX=SQLMSS , $
SEGMENT=TSTEST, SEGTYPE=S0, $
  FIELDNAME=I, ALIAS=I, USAGE=I11, ACTUAL=I4,
  MISSING=ON, $
  FIELDNAME=TS, ALIAS=TS, USAGE=A16, ACTUAL=A16, FIELDTYPE=R, $
```

**Note:** When you generate a synonym for a table with a TIMESTAMP column, the TIMESTAMP column is created as read-only (FIELDTYPE=R).

TSTOPACK converts the timestamp column TS to packed decimal:

```
TSNUM/P21=TSTOPACK(TS,'P21');
```

For 0000000000007815, the result is 30741.

For 0000000000007816, the result is 30742.
UFMT: Converting an Alphanumeric String to Hexadecimal

The UFMT function converts characters in an alphanumeric source string to their hexadecimal representation. This function is useful for examining data of unknown format. As long as you know the length of the data, you can examine its content.

Syntax: How to Convert an Alphanumeric String to Hexadecimal

UFMT(source_string, length, output)

where:

source_string
Alphanumeric
Is the alphanumeric string to convert.

length
Integer
Is the number of characters in source_string.

output
Alphanumeric
The format of output must be alphanumeric and its length must be twice that of length.

Example: Converting an Alphanumeric String to Hexadecimal

UFMT converts each value in JOBCODE to its hexadecimal representation and stores it in a column with the format A6.

UFMT(JOBCODE, 3, 'A6')

For A01, the result is C1F0F1.
For A02, the result is C1F0F2.

XTPACK: Writing a Packed Number With Up to 31 Significant Digits to an Output File

The XTPACK function stores packed numbers with up to 31 significant digits in an alphanumeric field, retaining decimal data. This permits writing a short or long packed field of any length, 1 to 16 bytes, to an output file.
Syntax: How to Store Packed Values in an Alphanumeric Field

\[
\text{XTPACK}(\text{in\_value}, \text{outlength}, \text{outdec, output})
\]

where:

- **infield**
  Numeric
  Is the packed value.

- **outlength**
  Numeric
  Is the length of the alphanumeric field that will hold the converted packed field. Can be from 1 to 16.

- **outdec**
  Numeric
  Is the number of decimal positions for **output**.

- **output**
  Alphanumeric

Example: Writing a Long Packed Number to an Output File

XTPACK converts LONGPCK to alphanumeric so that it can be saved in an output file:

\[
\text{XTPACK(\text{LONGPCK},13,2,\text{'}A13\text{'})};
\]
Simplified Numeric Functions

Numeric functions have been developed that make it easier to understand and enter the required arguments. These functions have streamlined parameter lists, similar to those used by SQL functions. In some cases, these simplified functions provide slightly different functionality than previous versions of similar functions.

The simplified functions do not have an output argument. Each function returns a value that has a specific data type.

When used in a request against a relational data source, these functions are optimized (passed to the RDBMS for processing).

Note:

- The simplified numeric functions are supported in Dialogue Manager.

In this chapter:

- CEILING: Returning the Smallest Integer Value Greater Than or Equal to a Value
- EXPONENT: Raising e to a Power
- FLOOR: Returning the Largest Integer Less Than or Equal to a Value
- MOD: Calculating the Remainder From a Division
- POWER: Raising a Value to a Power

CEILING: Returning the Smallest Integer Value Greater Than or Equal to a Value

CEILING returns the smallest integer value that is greater than or equal to a number.

Syntax:

How to Return the Smallest Integer Greater Than or Equal to a Number

CEILING(number)

where:

number

Numeric

Is the number whose ceiling will be returned. The output data type is the same as the input data type.
**Example:** Returning the Ceiling of a Number

CEILING returns the smallest integer larger than the value in GROSS_PROFIT_US:

\[
\text{CEILING(GROSS\_PROFIT\_US)}
\]

For 225.98, the output is 226.00.

For -30.01, the output is -30.00.

**EXPONENT: Raising e to a Power**

EXPONENT raises the constant e to a power.

**Syntax:** How to Raise the Constant e to a Power

\[
\text{EXPONENT(power)}
\]

where:

\[
\text{power}
\]

Numeric

Is the power to which to raise e. The output data type is numeric.

**Example:** Raising e to a Power

For EXPONENT(1), the value is 2.71828

For EXPONENT(5), the value is 148.41316

**FLOOR: Returning the Largest Integer Less Than or Equal to a Value**

FLOOR returns the largest integer value that is less than or equal to a number.

**Syntax:** How to Return the Largest Integer Less Than or Equal to a Number

\[
\text{FLOOR(number)}
\]

where:

\[
\text{number}
\]

Numeric

Is the number whose floor will be returned. The output data type is the same as the input data type.
**Example:** Returning the Floor of a Number

FLOOR returns the smallest integer larger than the value in GROSS_PROFIT_US:

\[
\text{FLOOR(GROSS\_PROFIT\_US)}
\]

For 225.98, the output is 225.00.
For -30.01, the output is -31.00.

**MOD: Calculating the Remainder From a Division**

MOD calculates the remainder from a division. The output data type is the same as the input data type.

**Syntax:** How to Calculate the Remainder From a Division

\[
\text{MOD(dividend, divisor)}
\]

where:

- **dividend**
  - Numeric
  - Is the value to divide.
  - **Note:** The sign of the returned value will be the same as the sign of the dividend.

- **divisor**
  - Numeric
  - Is the value to divide by.
  - If the divisor is zero (0), the dividend is returned.

**Example:** Calculating the Remainder From a Division

MOD returns the remainder of PRICE_DOLLARS divided by DAYSDELAYED

\[
\text{MOD(PRICE\_DOLLARS, DAYSDELAYED)}
\]

For 399.00/3, the value is zero (0).
For 489.00/3, the value is .99.

**POWER: Raising a Value to a Power**

POWER raises a base value to a power.
Syntax: How to Raise a Value to a Power

\[ \text{POWER}(\text{base}, \text{power}) \]

where:

base

Numeric

Is the value to raise to a power. The output value has the same data type as the base value. If the base value is integer, negative power values will result in truncation.

power

Numeric

Is the power to which to raise the base value.

Example: Raising a Base Value to a Power

Power returns the value COGS_US/20.00 raised to the power stored in DAYSDELAYED.

\[ \text{POWER1} = \text{POWER(COGS_US/20.00, DAYSDELAYED)} \]

For base 12.15 and power 3, the value is 1,793.61
Chapter 14

Numeric Functions

Numeric functions perform calculations on numeric constants and fields.

**Note:** With CDN ON, numeric arguments must be delimited by a comma followed by a space.

**In this chapter:**
- ABS: Calculating Absolute Value
- CHKPCK: Validating a Packed Field
- DMOD, FMOD, and IMOD: Calculating the Remainder From a Division
- EXP: Raising e to the Nth Power
- EXPN: Evaluating a Number in Scientific Notation
- INT: Finding the Greatest Integer
- LOG: Calculating the Natural Logarithm
- MAX and MIN: Finding the Maximum or Minimum Value
- NORMSDST and NORMSINV: Calculating Normal Distributions
- PRDNOR and PRDUNI: Generating Reproducible Random Numbers
- RDNORM and RDUNIF: Generating Random Numbers
- SQRT: Calculating the Square Root

**ABS: Calculating Absolute Value**

The ABS function returns the absolute value of a number.
Syntax: How to Calculate Absolute Value

\[ \text{ABS}(\text{in\_value}) \]

where:

\[ \text{in\_value} \]

Numeric

Is the value for which the absolute value is returned. If you use an expression, use parentheses as needed to ensure the correct order of evaluation.

Example: Calculating Absolute Value

ABS calculates the absolute value of DIFF.

\[ \text{ABS(DIFF)}; \]

For 15, the result is 15.

For -2, the result is 2.

CHKPCK: Validating a Packed Field

The CHKPCK function validates the data in a field described as packed format (if available on your platform). The function prevents a data exception from occurring when a request reads a field that is expected to contain a valid packed number but does not.

To use CHKPCK:

1. Ensure that the Master File (USAGE and ACTUAL attributes) defines the field as alphanumeric, not packed. This does not change the field data, which remains packed, but it enables the request to read the data without a data exception.

2. Call CHKPCK to examine the field. The function returns the output to a field defined as packed. If the value it examines is a valid packed number, the function returns the value; if the value is not packed, the function returns an error code.

Syntax: How to Validate a Packed Field

\[ \text{CHKPCK}(\text{length}, \text{in\_value}, \text{error}, \text{output}) \]

where:

\[ \text{length} \]

Numeric

Is the number of bytes in the packed field. It can be between 1 and 16 bytes.
infield
Alphanumeric

Is the value to be verified as packed decimal. The value must be described as alphanumeric, not packed.

error
Numeric

Is the error code that the function returns if a value is not packed. Choose an error code outside the range of data. The error code is first truncated to an integer, then converted to packed format. However, it may appear on a report with a decimal point depending on the output format.

output
Packed-decimal

Example: Validating Packed Data

CHKPCK validates the values in PACK_SAL, and store the result in a column with the format P8CM. Values not in packed format return the error code -999. Values in packed format appear accurately.

CHKPCK(8, PACK_SAL, -999, 'P8CM')

DMOD, FMOD, and IMOD: Calculating the Remainder From a Division

The MOD functions calculate the remainder from a division. Each function returns the remainder in a different format.

The functions use the following formula.

\[ \text{remainder} = \text{dividend} - \text{INT}(\text{dividend}/\text{divisor}) \times \text{divisor} \]

- **DMOD** returns the remainder as a decimal number.
- **FMOD** returns the remainder as a floating-point number.
- **IMOD** returns the remainder as an integer.

For information on the INT function, see INT: Finding the Greatest Integer on page 304.
Syntax:  How to Calculate the Remainder From a Division

\[ function(dividend, divisor, output) \]

where:

\[ function \]
Is one of the following:

- **DMOD** returns the remainder as a decimal number.
- **FMOD** returns the remainder as a floating-point number.
- **IMOD** returns the remainder as an integer.

\[ dividend \]
Numeric
Is the number being divided.

\[ divisor \]
Numeric
Is the number dividing the dividend.

\[ output \]
Numeric
Is the result whose format is determined by the function used.
If the divisor is zero (0), the dividend is returned.

Example:  Calculating the Remainder From a Division

IMOD divides ACCTNUMBER by 1000 and stores the remainder in a column with the format I3L.

\[ IMOD(ACCTNUMBER, 1000, 'I3L') \]

For 122850108, the result is 108.
For 163800144, the result is 144.

EXP: Raising e to the Nth Power

The EXP function raises the value "e" (approximately 2.72) to a specified power. This function is the inverse of the LOG function, which returns the logarithm of the argument.
EXP calculates the result by adding terms of an infinite series. If a term adds less than 0.000001 percent to the sum, the function ends the calculation and returns the result as a double-precision number.

**Syntax:**  How to Raise \(e\) to the Nth Power

\[
\text{EXP}(\text{power}, \ \text{output})
\]

where:

**power**

Numeric

Is the power to which \(e\) is raised.

**output**

Double-precision floating-point

**Example:**  Raising \(e\) to the Nth Power

EXP raises \(e\) to the power designated by the \&POW variable, specified here as 3. The result is then rounded to the nearest integer with the .5 rounding constant. The result has the format D15.3.

\[
\text{EXP}(&\text{POW}, \ 'D15.3') + 0.5;
\]

For 3, the result is APPROXIMATELY 20.

**EXPN: Evaluating a Number in Scientific Notation**

The EXPN function evaluates a numeric literal or Dialogue Manager variable expressed in scientific notation.

**Syntax:**  How to Evaluate a Number in Scientific Notation

\[
\text{EXPN}(n.nn \ {E|D} \ (+|-) \ p)
\]

where:

**n.nn**

Numeric

Is a numeric literal that consists of a whole number component, followed by a decimal point, followed by a fractional component.

**E, D**
Denotes scientific notation. E and D are interchangeable.

+, −

Indicates if $p$ is positive or negative.

$p$

Integer

Is the power of 10 to which to raise $n.nn$.

**Note:** EXPN does not use an output argument. The format of the result is floating-point double precision.

**Example:** Evaluating a Number in Scientific Notation

EXPN evaluates 1.03E+2.

```
EXPN(1.03E+2)
```

The result is 103.

**INT: Finding the Greatest Integer**

The INT function returns the integer component of a number.

**Syntax:** How to Find the Greatest Integer

```
INT(in_value)
```

where:

```
in_value
   Numeric
```

Is the value for which the integer component is returned. If you supply an expression, use parentheses as needed to ensure the correct order of evaluation.

**Note:** INT does not use an output argument. The format of the result is floating-point double precision.
**Example:** Finding the Greatest Integer

INT finds the greatest integer in DED_AMT.

\[
\text{INT(DED\_AMT)}
\]

For $1,261.40, the result is 1261.

For $1,668.69, the result is 1668.

**LOG: Calculating the Natural Logarithm**

The LOG function returns the natural logarithm of a number.

**Syntax:**

How to Calculate the Natural Logarithm

\[
\text{LOG(in\_value)}
\]

where:

\[
\text{in\_value}
\]

Numeric

Is the value for which the natural logarithm is calculated. If you supply an expression, use parentheses as needed to ensure the correct order of evaluation. If \( \text{in\_value} \) is less than or equal to 0, LOG returns 0.

**Note:** LOG does not use an output argument. The format of the result is floating-point double precision.

**Example:** Calculating the Natural Logarithm

LOG calculates the logarithm of CURR_SAL.

\[
\text{LOG(CURR\_SAL)}
\]

For $29,700.00, the result is 10.30.

For $26,862.00, the result is 10.20.

**MAX and MIN: Finding the Maximum or Minimum Value**

The MAX and MIN functions return the maximum or minimum value, respectively, from a list of values.
**Syntax:** How to Find the Maximum or Minimum Value

\[ \text{MAX|MIN}(\text{value1, value2, ...}) \]

where:

**MAX**

Returns the maximum value.

**MIN**

Returns the minimum value.

**value1, value2**

Numeric

Are the values for which the maximum or minimum value is returned. If you supply an expression, use parentheses as needed to ensure the correct order of evaluation.

**Note:** MAX and MIN do not use an output argument. The format of the result is floating-point double precision.

**Example:** Determining the Minimum Value

MIN returns either the value of ED_HRS or the constant 30, whichever is lower.

\[ \text{MIN}(\text{ED_HRS, 30}) \]

For 45.00, the result is 30.00.

For 25.00, the result is 25.00.

**NORMSDST and NORMSINV: Calculating Normal Distributions**

The NORMSDST and NORMSINV functions perform calculations on a standard normal distribution curve. NORMSDST calculates the percentage of data values that are less than or equal to a normalized value; NORMSINV is the inverse of NORMSDST, calculates the normalized value that forms the upper boundary of a percentile in a standard normal distribution curve.

**NORMSDST: Calculating Standard Cumulative Normal Distribution**

The NORMSDST function performs calculations on a standard normal distribution curve, calculating the percentage of data values that are less than or equal to a normalized value. A normalized value is a point on the X-axis of a standard normal distribution curve in standard deviations from the mean. This is useful for determining percentiles in normally distributed data.
The NORMSINV function is the inverse of NORMSDIST. For information about NORMSINV, see *NORMSINV: Calculating Inverse Cumulative Normal Distribution* on page 309.

The results of NORMSDIST are returned as double-precision and are accurate to 6 significant digits.

A standard normal distribution curve is a normal distribution that has a mean of 0 and a standard deviation of 1. The total area under this curve is 1. A point on the X-axis of the standard normal distribution is called a normalized value. Assuming that your data is normally distributed, you can convert a data point to a normalized value to find the percentage of scores that are less than or equal to the raw score.

You can convert a value (raw score) from your normally distributed data to the equivalent normalized value (z-score) as follows:

\[ z = \frac{\text{raw score} - \text{mean}}{\text{standard deviation}} \]

To convert from a z-score back to a raw score, use the following formula:

\[ \text{raw score} = z \times \text{standard deviation} + \text{mean} \]

The mean of data points \( x_i \), where \( i \) is from 1 to \( n \) is:

\[ \frac{\sum x_i}{n} \]

The standard deviation of data points \( x_i \), where \( i \) is from 1 to \( n \) is:

\[ \sqrt{\left( \frac{\sum x_i^2 - \left( \sum x_i \right)^2/n}{n - 1} \right)} \]
The following diagram illustrates the results of the NORMSDST and NORMSINV functions.

Reference:  **Characteristics of the Normal Distribution**

Many common measurements are normally distributed. A plot of normally distributed data values approximates a bell-shaped curve. The two measures required to describe any normal distribution are the mean and the standard deviation:

- The mean is the point at the center of the curve.
- The standard deviation describes the spread of the curve. It is the distance from the mean to the point of inflection (where the curve changes direction).

Syntax:  **How to Calculate the Cumulative Standard Normal Distribution Function**

```
NORMSDST(value, 'D8');
```

where:

`value`

Is a normalized value.
Is the required format for the result. The value returned by the function is double-precision. You can assign it to a field with any valid numeric format.

Example: Using the NORMSDST Function

NORMSDST finds the percentile for Z and stores the result in a column with the format D8.

\[
\text{NORMSDST}(Z, \text{'}D8\text{'})
\]

For -.07298, the result is .47091.
For -.80273 the result is .21106.

NORMSINV: Calculating Inverse Cumulative Normal Distribution

The NORMSINV function performs calculations on a standard normal distribution curve, finding the normalized value that forms the upper boundary of a percentile in a standard normal distribution curve. This is the inverse of NORMSDST. For information about NORMSDST, see NORMSDST: Calculating Standard Cumulative Normal Distribution on page 306.

The results of NORMSINV are returned as double-precision and are accurate to 6 significant digits.

Syntax: How to Calculate the Inverse Cumulative Standard Normal Distribution Function

\[
\text{NORMSINV}(value, \text{'}D8\text{'})
\]

where:

value

Is a number between 0 and 1 (which represents a percentile in a standard normal distribution).

D8

Is the required format for the result. The value returned by the function is double-precision. You can assign it to a field with any valid numeric format.
**Example: Using the NORMSINV Function**

NORMSINV returns a normalized value from a percentile found using NORMSDST.

\[
\text{NORMSINV} (\text{NORMSD}, \ '\text{D8}')
\]

For .21106, the result is -.80273.
For .47091, the result is -.07298

**PRDNOR and PRDUNI: Generating Reproducible Random Numbers**

The PRDNOR and PRDUNI functions generate reproducible random numbers:

- PRDNOR generates reproducible double-precision random numbers normally distributed with an arithmetic mean of 0 and a standard deviation of 1.
- PRDUNI generates reproducible double-precision random numbers uniformly distributed between 0 and 1 (that is, any random number it generates has an equal probability of being anywhere between 0 and 1).

**Syntax:** How to Generate Reproducible Random Numbers

\[
\text{\{PRDNOR|PRDUNI\} (seed, output)}
\]

where:

**PRDNOR**

Generates reproducible double-precision random numbers normally distributed with an arithmetic mean of 0 and a standard deviation of 1.

**PRDUNI**

Generates reproducible double-precision random numbers uniformly distributed between 0 and 1.

**seed**

Numeric

Is the seed or the field that contains the seed, up to 9 digits. The seed is truncated to an integer.

**output**

Double-precision

**Example: Generating Reproducible Random Numbers**

PRDNOR assigns random numbers and stores them in a column with the format D12.2.
RDNORM and RDUNIF: Generating Random Numbers

The RDNORM and RDUNIF functions generate random numbers:

- RDNORM generates double-precision random numbers normally distributed with an arithmetic mean of 0 and a standard deviation of 1.
- RDUNIF generates double-precision random numbers uniformly distributed between 0 and 1 (that is, any random number it generates has an equal probability of being anywhere between 0 and 1).

Syntax: How to Generate Random Numbers

{RDNORM | RDUNIF}(output)

where:

RDNORM

Generates double-precision random numbers normally distributed with an arithmetic mean of 0 and a standard deviation of 1.

RDUNIF

Generates double-precision random numbers uniformly distributed between 0 and 1.

output

Double-precision

Example: Generating Random Numbers

RDNORM assigns random numbers and stores them in a column with the format D12.2.

RDNORM('D12.2')

SQRT: Calculating the Square Root

The SQRT function calculates the square root of a number.
Syntax: How to Calculate the Square Root

\[
\text{SQRT}(\text{in\_value})
\]

where:

\[
\text{in\_value}
\]

Numeric

Is the value for which the square root is calculated. If you supply an expression, use parentheses as needed to ensure the correct order of evaluation. If you supply a negative number, the result is zero.

Note: SQRT does not use an output argument. The result of the function is floating-point double precision.

Example: Calculating the Square Root

SQRT calculates the square root of LISTPR.

\[
\text{SQRT} \ (\text{LISTPR})
\]

For 19.98, the result is 4.47.

For 14.98, the result is 3.87.
Simplified statistical functions can be called in a COMPUTE command to perform statistical calculations on the internal matrix that is generated during TABLE request processing. The STDDEV and CORRELATION functions can also be called as a verb object in a display command. Prior to calling a statistical function, you need to establish the size of the partition on which these functions will operate, if the request contains sort fields.

Note: It is recommended that all numbers and fields used as parameters to these functions be double-precision.

In this chapter:

- Specify the Partition Size for Simplified Statistical Functions
- CORRELATION: Calculating the Degree of Correlation Between Two Sets of Data
- KMEANS_CLUSTER: Partitioning Observations Into Clusters Based on the Nearest Mean Value
- MULTIREGRESS: Creating a Multivariate Linear Regression Column
- OUTLIER: Identifying Outliers in Numeric Data
- RSERVE: Running an R Script
- STDDEV: Calculating the Standard Deviation for a Set of Data Values

### Specify the Partition Size for Simplified Statistical Functions

```plaintext
SET PARTITION_ON = {FIRST | PENULTIMATE | TABLE}
```

where:

**FIRST**

Uses the first (also called the major) sort field in the request to partition the values.

**PENULTIMATE**

Uses the next to last sort field where the COMPUTE is evaluated to partition the values. This is the default value.
CORRELATION: Calculating the Degree of Correlation Between Two Sets of Data

The CORRELATION function calculates the correlation coefficient between two numeric fields. The function returns a numeric value between zero (-1.0) and 1.0.

**Syntax:** How to Calculate the Correlation Coefficient Between Two Fields

```
CORRELATION(field1, field2)
```

where:

- **field1**
  - Numeric
  - Is the first set of data for the correlation.

- **field2**
  - Numeric
  - Is the second set of data for the correlation.

**Note:** Arguments for CORRELATION cannot be prefixed fields. If you need to work with fields that have a prefix operator applied, apply the prefix operators to the fields in COMPUTE commands and save the results in a HOLD file. Then, run the correlation against the HOLD file.

**Example:** Calculating a Correlation

CORRELATION calculates the correlation between DOLLARS and BUDDOLLARS.

```
CORRELATION(DOLLARS, BUDDOLLARS)
```

For DOLLARS=46,156,290.00 and BUDDOLLARS=46,220,778.00, the result is 0.895691073.

KMEANS_CLUSTER: Partitioning Observations Into Clusters Based on the Nearest Mean Value

The KMEANS_CLUSTER function partitions observations into a specified number of clusters based on the nearest mean value. The function returns the cluster number assigned to the field value passed as a parameter.

**Note:** If there are not enough points to create the number of clusters requested, the value -10 is returned for any cluster that cannot be created.
**Syntax:** How to Partition Observations Into Clusters Based on the Nearest Mean Value

KMEANS_CLUSTER(number, percent, iterations, tolerance, 
[prefix1.]field1[, [prefix1.]field2 ...])

where:

**number**

Integer

- Is number of clusters to extract.

**percent**

Numeric

- Is the percent of training set size (the percent of the total data to use in the calculations).
  - The default value is AUTO, which uses the internal default percent.

**iterations**

Integer

- Is the maximum number of times to recalculate using the means previously generated. The default value is AUTO, which uses the internal default number of iterations.

**tolerance**

Numeric

- Is a weight value between zero (0) and 1.0. The value AUTO uses the internal default tolerance.

**prefix1, prefix2**

- Defines an optional aggregation operator to apply to the field before using it in the calculation. Valid operators are:
  - **SUM.** which calculates the sum of the field values. SUM is the default value.
  - **CNT.** which calculates a count of the field values.
  - **AVE.** which calculates the average of the field values.
  - **MIN.** which calculates the minimum of the field values.
  - **MAX.** which calculates the maximum of the field values.
  - **FST.** which retrieves the first value of the field.
  - **LST.** which retrieves the last value of the field.

**Note:** The operators PCT., RPCT., TOT., MDN., MDE., RNK., and DST. are not supported.
field1
Numeric
Is the set of data to be analyzed.

field2
Numeric
Is an optional set of data to be analyzed.

Example:  Partitioning Data Values Into Clusters
The following request partitions the DOLLARS field values into four clusters and displays the result as a scatter chart in which the color represents the cluster. The request uses the default values for the percent, iterations, and tolerance parameters by passing them as the value 0 (zero).

```
SET PARTITION_ON = PENULTIMATE
GRAPH FILE GGSALES
PRINT UNITS DOLLARS
COMPUTE KMEAN1/D20.2 TITLE 'K-MEANS' = KMEANS_CLUSTER(4, AUTO, AUTO, AUTO, AUTO, DOLLARS);
ON GRAPH SET LOOKGRAPH SCATTER
ON GRAPH PCHOLD FORMAT JSCHART
ON GRAPH SET STYLE *
INCLUDE=Warm.sty, $
type = data, column = N2, bucket=y-axis, $
type=data, column= N1, bucket=x-axis, $
type=data, column=N3, bucket=color, $
GRID=OFF,$
*GRAPH_JS_FINAL
colorScale: { 
   colorMode: 'discrete',
   colorBands: [{start: 1, stop: 1.99, color: 'red'}, {start: 2, stop: 2.99, color: 'green'},
               {start: 3, stop: 3.99, color: 'yellow'}, {start: 3.99, stop: 4, color: 'blue'} ]
}
*END
ENDSTYLE
END
```
MULTIREGRESS: Creating a Multivariate Linear Regression Column

MULTIREGRESS derives a linear equation that best fits a set of numeric data points, and uses this equation to create a new column in the report output. The equation can be based on one or more independent variables.

The equation generated is of the following form, where \( y \) is the dependent variable and \( x_1, x_2, \) and \( x_3 \) are the independent variables.

\[
y = a_1 x_1 + a_2 x_2 + a_3 x_3 + \ldots + b
\]

When there is one independent variable, the equation represents a straight line. When there are two independent variables, the equation represents a plane, and with three independent variables, it represents a hyperplane. You should use this technique when you have reason to believe that the dependent variable can be approximated by a linear combination of the independent variables.

**Syntax:** How to Create a Multivariate Linear Regression Column

\[
\text{MULTIREGRESS}(\text{input\_field1}, [\text{input\_field2}, \ldots])
\]
where:

\[ \text{input\_field1, input\_field2 ...} \]

Are any number of field names to be used as the independent variables. They should be independent of each other. If an input field is non-numeric, it will be categorized to transform it to numeric values that can be used in the linear regression calculation.

**Example:** Creating a Multivariate Linear Regression Column

The following request uses the DOLLARS and BUDDOLLARS fields to generate a regression column named Estimated_Dollars.

```
GRAPH FILE GGSALES
SUM BUDUNITS UNITS BUDDOLLARS DOLLARS
COMPUTE Estimated_Dollars/F8 = MULTIREGRESS(DOLLARS, BUDDOLLARS);
BY DATE
ON GRAPH SET LOOKGRAPH LINE
ON GRAPH PCHOLD FORMAT JSCHART
ON GRAPH SET STYLE *
INCLUDE=Warm.sty,$
type=data, column = n1, bucket = x-axis,$
type=data, column= dollars, bucket=y-axis,$
type=data, column= buddollars, bucket=y-axis,$
type=data, column= Estimated_Dollars, bucket=y-axis,$
*GRAPH_JS
"series":[
{"series":2, "color":"orange"}]
*END
ENDSTYLE
END
```
OUTLIER: Identifying Outliers in Numeric Data

The output is shown in the following image. The orange line represents the regression equation.

The 1.5 * IQR (Inner Quartile Range) rule is a common way to identify outliers in data. This rule defines an outlier as a value that is above or below 1.5 times the inner quartile range in the data. The inner quartile range is based on sorting the data values, dividing it into equal quarters, and calculating the range of values between the first quartile (the value one quarter of the way through the sorted data) and third quartile (the value three quarters of the way through the sorted data). The value that is 1.5 times below the inner quartile range is called the lower fence, and the value that is 1.5 times above the inner quartile range is called the upper fence.

OUTLIER is not supported in a DEFINE expression. It can be used in a COMPUTE expression or a WHERE, WHERE TOTAL, or WHERE_GROUPED phrase.

Given a numeric field as input, OUTLIER returns one of the following values for each value of the field, using the 1.5 * IQR rule:

- **0 (zero)**. The value is not an outlier.
- **-1**. The value is below the lower fence.
- **1**. The value is above the upper fence.
Syntax: How to Identify Outliers in Numeric Data

\texttt{OUTLIER(input\_field)}

where:

\texttt{input\_field}

\texttt{Numeric}

Is the numeric field to be analyzed.

Example: Identifying Outliers

The following request defines the SALES field to have different values depending on the store code, and uses OUTLIER to determine whether each field value is an outlier.

\texttt{DEFINE FILE GGSALES}
\texttt{SALES/D12 = IF ((CATEGORY EQ 'Coffee') AND (STCD EQ 'R1019')) THEN 19000}
\texttt{ELSE IF ((CATEGORY EQ 'Coffee') AND (STCD EQ 'R1020')) THEN 20000}
\texttt{ELSE IF ((CATEGORY EQ 'Coffee') AND (STCD EQ 'R1040')) THEN 7000}
\texttt{ELSE DOLLARS;}
\texttt{END}
\texttt{TABLE FILE GGSALES}
\texttt{SUM SALES}
\texttt{COMPUTE OUT1/I3 = OUTLIER(SALES);}
\texttt{BY CATEGORY}
\texttt{BY STCD}
\texttt{WHERE CATEGORY EQ 'Coffee'}
\texttt{ON TABLE SET PAGE NOLEAD}
\texttt{ON TABLE SET STYLE *}
\texttt{GRID=OFF,$}
\texttt{ENDSTYLE}
\texttt{END}
RSERVE: Running an R Script

You can use the RSERVE function in a COMPUTE command to run an R script that returns vector output. This requires that you have a configured Adapter for Rserve.

Syntax: How to Run an R Script

```
RSERVE(rserve_mf, input_field1, ...input_fieldn, output)
```

where:

- `rserve_mf`
  - Is the synonym for the R script.

- `input_field1, ...input_fieldn`
  - Are the independent variables used by the R script.

- `output`
  - Is the dependent variable returned by the R script. It must be a single column (vector) of output.
Example: Using RSERVE to Run an R Script

The R script named wine_run_model.R predicts Bordeaux wine prices based on the average growing season temperature, the amount of rain during the harvest season, the amount of rain during the winter, and the age of the wine.

Using a configured connection (named MyRserve) for the Adapter for Rserve, and a sample data file named wine_input_sample.csv, you create the following synonym for the R script, as described in the Adapter Administration manual.

Master File

FILENAME=WINE_RUN_MODEL, SUFFIX=RSERVE , $  
SEGMENT=INPUT_DATA, SEGTYPE=S0, $  
    FIELDNAME=AGST, ALIAS=AGST, USAGE=D9.4, ACTUAL=STRING,  
        MISSING=ON,  
        TITLE='AGST', $  
    FIELDNAME=HARVESTRAIN, ALIAS=HarvestRain, USAGE=I11, ACTUAL=STRING,  
        MISSING=ON,  
        TITLE='HarvestRain', $  
    FIELDNAME=WINTERRAIN, ALIAS=WinterRain, USAGE=I11, ACTUAL=STRING,  
        MISSING=ON,  
        TITLE='WinterRain', $  
    FIELDNAME=AGE, ALIAS=Age, USAGE=I11, ACTUAL=STRING,  
        MISSING=ON,  
        TITLE='Age', $  
SEGMENT=OUTPUT_DATA, SEGTYPE=U, PARENT=INPUT_DATA, $  
    FIELDNAME=PRICE, ALIAS=Price, USAGE=D18.14, ACTUAL=STRING,  
        MISSING=ON,  
        TITLE='Price', $

Access File

SEGNAME=INPUT_DATA,  
    CONNECTION=MyRserve,  
    R_SCRIPT=/prediction/wine_run_model.r,  
    R_SCRIPT_LOCATION=WFRS,  
    R_INPUT_SAMPLE_DAT=prediction/wine_input_sample.csv, $
Now that the synonym has been created for the model, the model will be used to run against the following data file named wine_forecast.csv.

<table>

STDDEV: Calculating the Standard Deviation for a Set of Data Values

The STDDEV function returns a numeric value that represents the amount of dispersion in the data. The set of data can be specified as the entire population or a sample. The standard deviation is the square root of the variance, which is a measure of how observations deviate from their expected value (mean). If specified as a population, the divisor in the standard deviation calculation (also called degrees of freedom) will be the total number of data points, N. If specified as a sample, the divisor will be N-1.

If $x_i$ is an observation, $N$ is the number of observations, and $\mu$ is the mean of all of the observations, the formula for calculating the standard deviation for a population is:

$$\sqrt{\frac{1}{N} \sum_{i=1}^{N} (x_i - \mu)^2}$$

To calculate the standard deviation for a sample, the mean is calculated using the sample observations, and the divisor is N-1 instead of N.

Reference: Calculate the Standard Deviation in a Set of Data

\[
\text{STDDEV}(\text{field, sampling})
\]

where:

\textbf{field}  
Numeric  
Is the set of observations for the standard deviation calculation.

\textbf{sampling}  
Keyword  
Indicates the origin of the data set. Can be one of the following values.

- P Entire population.
- S Sample of population.

Note: Arguments for STDDEV cannot be prefixed fields. If you need to work with fields that have a prefix operator applied, apply the prefix operators to the fields in COMPUTE commands and save the results in a HOLD file. Then, run the standard deviation against the HOLD file.
Example: Calculating a Standard Deviation

STDDEV calculates the standard deviation of DOLLARS.

\[ \text{STDDEV(DOLLARS, S)} \]

The result is \(6,157.711080272\).
STDDEV: Calculating the Standard Deviation for a Set of Data Values
Chapter 16

Simplified System Functions

Simplified system functions have streamlined parameter lists, similar to those used by SQL functions. In some cases, these simplified functions provide slightly different functionality than previous versions of similar functions.

The simplified functions do not have an output argument. Each function returns a value that has a specific data type.

When used in a request against a relational data source, these functions are optimized (passed to the RDBMS for processing).

In this chapter:

- EDAPRINT: Inserting a Custom Message in the EDAPRINT Log File
- ENCRYPT: Encrypting a Password
- GETENV: Retrieving the Value of an Environment Variable
- PUTENV: Assigning a Value to an Environment Variable
- SLACK: Posting a Message to a Slack Channel

EDAPRINT: Inserting a Custom Message in the EDAPRINT Log File

Syntax: How to Insert a Message in the EDAPRINT Log File

EDAPRINT(message_type, 'message')

where:

message_type
Keyword
Can be one of the following message types.

- **I.** Informational message.
- **W.** Warning message.
- **E.** Error message.
ENCRIPT: Encrypting a Password

'message'

Is the message to insert, enclosed in single quotation marks.

Example: Inserting a Custom Message in the EDAPRINT Log File

The following procedure inserts three messages in the EDAPRINT log file.

-SET &I = EDAPRINT(I, 'This is a test informational message');
-SET &W = EDAPRINT(W, 'This is a test warning message');
-SET &E = EDAPRINT(E, 'This is a test error message');

ENCRIPT: Encrypting a Password

The ENCRIPT function encrypts an alphanumeric input value using the encryption algorithm configured in the server. The result is returned as variable length alphanumeric.

Syntax: How to Encrypt a Password

ENCRIPT(password)

where:

password
    Fixed length alphanumeric
    Is the value to be encrypted.

Example: Encrypting a Password

ENCRIPT encrypts the password guestpassword.

ENCRIPT('guestpassword')

The returned encrypted value is {AES}963AFA754E1763ABE697E8C5E764115E.

GETENV: Retrieving the Value of an Environment Variable

The GETENV function takes the name of an environment variable and returns its value as a variable length alphanumeric value.

Syntax: How to Retrieve the Value of an Environment Variable

GETENV(var_name)
where:

\textit{\texttt{var\_name}}

fixed length alphanumeric

Is the name of the environment variable whose value is being retrieved.

\textbf{Example: Retriving the Value of an Environment Variable}

GETENV retrieves the value of the server variable EDAEXTSEC.

\texttt{GETENV('EDAEXTSEC')}

The value returned is ON if the server was started with security on or OFF if the server was started with security off.

\textbf{PUTENV: Assigning a Value to an Environment Variable}

The PUTENV function assigns a value to an environment variable. The function returns an integer return code whose value is 1 (one) if the assignment is not successful or 0 (zero) if it is successful.

\textbf{Syntax: How to Assign a Value to an Environment Variable}

\texttt{PUTENV(var\_name, var\_value)}

where:

\textit{\texttt{var\_name}}

Fixed length alphanumeric

Is the name of the environment variable to be set.

\textit{\texttt{var\_value}}

Alphanumeric

Is the value you want to assign to the variable.

\textbf{Example: Assigning a Value to the UNIX PS1 Variable}

PUTENV assigns the value \textit{FOCUS/Shell:} to the UNIX PS1 variable.

\texttt{PUTENV('PS1','FOCUS/Shell:')}

This causes UNIX to display the following prompt when the user issues the UNIX shell command SH:

\textit{FOCUS/Shell:}
SLACK: Posting a Message to a Slack Channel

SLACK posts a message to a Slack channel from a WebFOCUS procedure:

- If the message is sent successfully, the function returns the value `true`.
- If the message is not sent successfully, the function returns a blank.

Syntax:

How to Post a Message to a Slack Channel

```
SLACK(workspace, channel, message)
```

where:

- `workspace` is a Workspace name.
- `channel` is a Channel name.
- `message` is an alphanumeric field containing the message.

Example: Sending a Slack Message From a WebFOCUS Request

The Adapter for Slack has been configured to have a connection to the devibi workspace, as shown in the following image.
The following request sends a Slack message to the `general` channel of the `devibi` Workspace, when the department is MIS.

```ibm
TABLE FILE ibisamp/EMPLOYEE
SUM
  CURR_SAL
AND COMPUTE SLACK_MESSAGE/A200 = 'Salary for Department ' || DEPARTMENT || ' is ' || LJJUST(20, FPRINT(CURR_SAL,'D12.2M'), 'A20');
AND COMPUTE CURR_SAL_SLACK/A20=IF DEPARTMENT EQ 'MIS'
    THEN SLACK('devibi', 'general', SLACK_MESSAGE) ELSE 'false';
AS 'Message Sent, to Slack highlighting, Salary'
BY DEPARTMENT
HEADING
"Slack"
"Slack Function Example"
ON TABLE SET PAGE-NUM NOLEAD
ON TABLE NOTOTAL
ON TABLE SET STYLE *
INCLUDE=IBFS:/FILE/IBI_HTML_DIR/javaassist/intl/EN/ENIADefault_combine.sty,
$ENDSTYLE
END
```

The output is shown in the following image.

- Slack
  - Slack Function Example

<table>
<thead>
<tr>
<th>DEPARTMENT</th>
<th>CURR_SAL</th>
<th>SLACK_MESSAGE</th>
<th>Message Sent to Slack highlighting Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIS</td>
<td>$108,002.00</td>
<td>Salary for Department MIS is $108,002.00</td>
<td>true</td>
</tr>
<tr>
<td>PRODUCTION</td>
<td>$114,282.00</td>
<td>Salary for Department PRODUCTION is $114,282.00</td>
<td>false</td>
</tr>
</tbody>
</table>

The message in the Slack channel is shown in the following image.

[Image showing the Slack message]
System Functions

System functions call the operating system to obtain information about the operating environment or to use a system service.

In this chapter:

- CLSDDREC: Closing All Files Opened by the PUTDDREC Function
- FEXERR: Retrieving an Error Message
- FGETENV: Retrieving the Value of an Environment Variable
- FPUTENV: Assigning a Value to an Environment Variable
- GETUSER: Retrieving a User ID
- JOBNAME: Retrieving the Current Process Identification String
- PUTDDREC: Writing a Character String as a Record in a Sequential File
- SLEEP: Suspending Execution for a Given Number of Seconds
- SYSVAR: Retrieving the Value of a z/OS System Variable

CLSDDREC: Closing All Files Opened by the PUTDDREC Function

The CLSDDREC function closes all files opened by the PUTDDREC function. If PUTDDREC is called in a Dialogue Manager -SET command, the files opened by PUTDDREC are not closed automatically until the end of a request or connection. In this case, you can close the files and free the memory used to store information about open file by calling the CLSDDREC function.

Syntax: How to Close All Files Opened by the PUTDDREC Function

\[
\text{CLSDDREC}(output)
\]

where:

\[
output
\]

Integer
Is the return code, which can be one of the following values:

- 0, which indicates that the files are closed.
- 1, which indicates an error while closing the files.

**Example:**

Closing Files Opened by the PUTDDREC Function

This example closes files opened by the PUTDDREC function:

```plaintext
CLSDDREC('I1')
```

**FEXERR: Retrieving an Error Message**

The FEXERR function retrieves an Information Builders error message. It is especially useful in a procedure using a command that suppresses the display of output messages.

An error message consists of up to four lines of text. The first line contains the message and the remaining three contain a detailed explanation, if one exists. FEXERR retrieves the first line of the error message.

**Syntax:**

**How to Retrieve an Error Message**

```plaintext
FEXERR(error, 'A72')
```

where:

- `error`
  Numeric
  Is the error number, up to 5 digits long.

- `'A72'`
  Is the format of the output value. The format is A72, the maximum length of an Information Builders error message.

**Example:**

Retrieving an Error Message

FEXERR retrieves the error message whose number is contained in the &ERR variable, in this case 650. The result has the format A72.

```plaintext
FEXERR(&ERR, 'A72')
```

The result is (FOC650) THE DISK IS NOT ACCESSED.
**FGETENV: Retrieving the Value of an Environment Variable**

The FGETENV function retrieves the value of an environment variable and returns it as an alphanumeric string.

**Syntax:** How to Retrieve the Value of an Environment Variable

\[ \text{FGETENV}(\text{length, 'varname', outlen, output}) \]

where:

- **length**
  - Integer
  - Is the number of characters in the environment variable name.

- **varname**
  - Alphanumeric
  - Is the name of the environment variable whose value is being retrieved.

- **outlen**
  - Integer
  - Is the length of the environment variable value returned.

- **output**
  - Alphanumeric
  - Is the format of the field in which the environment variable’s value is stored.

**FPUTENV: Assigning a Value to an Environment Variable**

Available Operating Systems: IBM i (formerly referred to as i5/OS), Tandem, UNIX, Windows

The FPUTENV function assigns a character string to an environment variable.

**Limit:** You cannot use FPUTENV to set or change FOCPRINT, FOCPATH, or USERPATH. Once started, these variables are held in memory and not reread from the environment.
Syntax: How to Assign a Value to an Environment Variable

FPUTENV (varname_length, 'varname', value_length, 'value', output)

where:

varname_length

Integer

Is the maximum number of characters in the name of the environment variable.

varname

Alphanumeric

Is the name of the environment variable. The name must be right-justified and padded with blanks to the maximum length specified by varname_length.

value_length

Is the maximum length of the environment variable value.

Note: The sum of varname_length and value_length cannot exceed 64.

value

Alphanumeric

Is the value you wish to assign to the environment variable. The string must be right-justified and contain no embedded blanks. Strings that contain embedded blanks are truncated at the first blank.

output

Integer

Is the return code. If the variable is set successfully, the return code is 0. Any other value indicates a failure occurred.

Example: Assigning a Value to an Environment Variable

FPUTENV assigns the value FOCUS/Shell to the PS1 variable and stores it in a field with the format A12:

-SET &RC = FPUTENV(3, 'PS1', 12, 'FOCUS/Shell:', 'I4');

The request displays the following prompt when the user issues the UNIX shell command SH:

FOCUS/Shell:
GETUSER: Retrieving a User ID

The GETUSER function retrieves the ID of the connected user.

Syntax: How to Retrieve a User ID

GETUSER(output)

where:

output

Alphanumeric, at least A8

Is the result field, whose length depends on the platform on which the function is issued. Provide a length as long as required for your platform; otherwise the output will be truncated.

Example: Retrieving a User ID

GETUSER retrieves the user ID of the person running the flow.

GETUSER(USERID)

JOBNAME: Retrieving the Current Process Identification String

The JOBNAME function retrieves the raw identification string of the current process from the operating system. This is also commonly known as a process PID at the operating system level. The function is valid in all environments, but is typically used in Dialogue Manager and returns the value as an alphanumeric string (even though a PID is pure numeric on some operating systems).

Note: JOBNAME strings differ between some operating systems in terms of look and length. For example, Windows, UNIX, and z/OS job names are pure numeric (typically a maximum of 8 characters long), while an OpenVMS job name is a hex number (always 8 characters long), and an IBM i job name is a three-part string that has a 26 character maximum length. Since an application may eventually be run in another (unexpected) environment in the future, it is good practice to use the maximum length of 26 to avoid accidental length truncation in the future. Applications using this function for anything more than simple identification may also need to account for the difference in the application code.
**Syntax:** How to Retrieve the Current Process Identification String

`JOBNAME(length, output)`

where:

*length*

Integer

Is the maximum number of characters to return from the PID system call.

*output*

Alphanumeric

Is the returned process identification string, whose length depends on the platform on which the function is issued. Provide a length as long as required for your platform. Otherwise, the output will be truncated.

**Example:** Retrieving a Process Identification String

The following example uses the `JOBNAME` function to retrieve the current process identification string to an A26 string and then truncate it for use in a `.TYPE` statement:

```plaintext
-SET &JOBNAME = JOBNAME(26, 'A26');
-SET &JOBNAME = TRUNCATE(&JOBNAME);
-TYPE The Current system PID &JOBNAME is processing.
```

For example, on Windows, the output is similar to the following:

```
The Current system PID 2536 is processing.
```
PUTDDREC: Writing a Character String as a Record in a Sequential File

The PUTDDREC function writes a character string as a record in a sequential file. The file must be identified with a FILEDEF (DYNAM on z/OS) command. If the file is defined as an existing file (with the APPEND option), the new record is appended. If the file is defined as NEW and it already exists, the new record overwrites the existing file.

PUTDDREC opens the file if it is not already open. Each call to PUTDDREC can use the same file or a new one. All of the files opened by PUTDDREC remain open until the end of a request or connection. At the end of the request or connection, all files opened by PUTDDREC are automatically closed.

If PUTDDREC is called in a Dialogue Manager -SET command, the files opened by PUTDDREC are not closed automatically until the end of a request or connection. In this case, you can close the files and free the memory used to store information about open file by calling the CLSDDREC function.

Syntax: How to Write a Character String as a Record in a Sequential File

PUTDDREC(ddname, dd_len, record_string, record_len, output)

where:

ddname
  Alphanumeric
  Is the logical name assigned to the sequential file in a FILEDEF command.

dd_len
  Numeric
  Is the number of characters in the logical name.

record_string
  Alphanumeric
  Is the character string to be added as the new record in the sequential file.

record_len
  Numeric
  Is the number of characters to add as the new record.
It cannot be larger than the number of characters in record_string. To write all of record_string to the file, record_len should equal the number of characters in record_string and should not exceed the record length declared in the command. If record_len is shorter than the declared length declared, the resulting file may contain extraneous characters at the end of each record. If record_string is longer than the declared length, record_string may be truncated in the resulting file.

output

Integer

Is the return code, which can have one of the following values:

0 - Record is added.
-1 - FILEDEF statement is not found.
-2 - Error while opening the file.
-3 - Error while adding the record to the file.

Example: Writing a Character String as a Record in a Sequential File

Using the CAR synonym as input,

FILEDEF LOGGING DISK baseapp/logging.dat

PUTDDREC('LOGGING', 7, 'Country:' | COUNTRY, 20, 'I5')

would return the value 0, and would write the following lines to logging.dat:

Country: ENGLAND
Country: JAPAN
Country: ITALY
Country: W GERMANY
Country: FRANCE

SLEEP: Suspending Execution for a Given Number of Seconds

The SLEEP function suspends execution for the number of seconds you specify as its input argument.

This function is only supported in Dialogue Manager. It is useful when you need to wait to start a specific procedure or application.
**Syntax:** How to Suspend Execution for a Specified Number of Seconds

\[ SLEEP(\text{delay}, \text{output}); \]

where:

\[ \text{delay} \]

Numeric

Is the number of seconds to delay execution. The number can be specified down to the millisecond.

\[ \text{output} \]

Numeric

The value returned is the same value you specify for \text{delay}.

**Example:** Suspending Execution for Four Seconds

SLEEP suspends execution for four seconds:

\[-\text{SET} \ &\text{DELAY} = \ SLEEP(4.0, \ 'I2');\]

**SYSVAR:** Retrieving the Value of a z/OS System Variable

Available Operating Systems: z/OS

The SYSVAR function populates a Dialogue Manager amper variable with the contents of any z/OS system variable. System variables are in the format \[\&\text{name}[,].\], where the dot is optional. They can be provided by the operating system or can be user defined. The function can be called in a -SET command.

**Syntax:** How to Retrieve the Value of a z/OS System Variable

\[-\text{SET} \ &\text{dmvar} = \ SYSVAR('\text{length}', '[\&\text{sysvar}][.]', '\text{outfmt}');\]

where:

\[ \&\text{dmvar} \]

Alphanumeric

Is the name of the Dialogue Manager variable to be populated with the value of the z/OS system variable.
length
  Alphanumeric

  Is the length of the next parameter in the call. Do not include the escape character in the length, if one is present in the sysvar argument.

[&|] sysvar[.]
  Alphanumeric

  Is the name of the system variable to be retrieved. Note that the ampersand (&) and the dot (.) are optional. If the ampersand is included, it must be followed by the escape character (|).

outfmt
  Alphanumeric

  Is the format of the returned value enclosed in single quotation marks.

**Example: Retrieving the Value of the z/OS SYSNAME Variable**

The following example populates the Dialogue Manager variable named &MYSNAME2 with the value of the z/OS SYSNAME variable:

```
-SET &MYSNAME2=SYSVAR('7','SYSNAME','A8');
-TYPE SYSNAME:&MYSNAME2
```

The output is similar to the following:

```
SYSNAME:IBI1
```
Chapter 18

Simplified Geography Functions

The simplified geography functions perform location-based calculations and retrieve geocoded points for various types of location data. They are used by the WebFOCUS location intelligence products that produce maps and charts. Some of the geography functions use GIS services and require valid credentials for accessing Esri ArcGIS proprietary data.

In this chapter:

- Sample Geography Files
- GIS_DISTANCE: Calculating the Distance Between Geometry Points
- GIS_DRIVE_ROUTE: Calculating the Driving Directions Between Geometry Points
- GIS_GEOCODE_ADDR: Geocoding a Complete Address
- GIS_GEOCODE_ADDR_CITY: Geocoding an Address Line, City, and State
- GIS_GEOCODE_ADDR_POSTAL: Geocoding an Address Line and Postal Code
- GIS_GEOMETRY: Building a JSON Geometry Object
- GIS_IN_POLYGON: Determining if a Point is in a Complex Polygon
- GIS_LINE: Building a JSON Line
- GIS_POINT: Building a Geometry Point
- GIS_REVERSE_COORDINATE: Returning a Geographic Component
- GIS_SERVICE_AREA: Calculating a Geometry Area Around a Given Point
- GIS_SERV_AREA_XY: Calculating a Service Area Around a Given Coordinate
Sample Geography Files

Some of the examples for the geography functions use geography sample files. One file, esri-citibike.csv has station names, latitudes and longitudes, and trip start times and end times. The other file, esri-geo10036.ftm has geometry data. To run the examples that use these files, create an application named esri, and place the following files into the application folder.

**esri-citibike.mas**

FILENAME=ESRI-CITIBIKE, SUFFIX=DFIX ,
DATASET=esri/esri-citibike.csv, $
SEGMENT=CITIBIKE_TRIPDATA, SEGTYPE=S0, $

18. Simplified Geography Functions

Functions Reference
The GIS_DISTANCE function uses a GIS service to calculate the distance between two geometry points.

**Syntax:**

```
GIS_DISTANCE(geo_point1, geo_point2)
```

where:

- `geo_point1` and `geo_point2`
  - Fixed length alphanumeric, large enough to hold the JSON describing the point (for example, A200).
  - Are the geometry points for which you want to calculate the distance.

**Note:** You can generate a geometry point using the GIS_POINT function.
**Example:** Calculating the Distance Between Two Geometry Points

The following uses a citibike .csv file that contains station names, latitudes and longitudes, and trip start times and end times. It uses the GIS_POINT function to define geometry points for start stations and end stations. It then uses GIS_DISTANCE to calculate the distance between them.

```
DEFINE FILE esri/esri-citibike
STARTPOINT/A200 = GIS_POINT('4326', START_STATION_LONGITUDE, START_STATION_LATITUDE);
ENDPOINT/A200 = GIS_POINT('4326', END_STATION_LONGITUDE, END_STATION_LATITUDE);
Distance/P10.2 = GIS_DISTANCE(ENDPOINT, STARTPOINT);
END
```

```
TABLE FILE esri/esri-citibike
PRINT END_STATION_NAME AS End Distance
BY START_STATION_NAME AS Start
ON TABLE SET PAGE NOLEAD
END
```
GIS_DRIVE_ROUTE: Calculating the Driving Directions Between Geometry Points

The output is shown in the following image.

<table>
<thead>
<tr>

GIS_DRIVE_ROUTE: Calculating the Driving Directions Between Geometry Points

The GIS_DRIVE_ROUTE function uses a GIS service to calculate the driving route between two geometry points.

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:**

GIS_DRIVE_ROUTE(geo_start_point, geo_end_point)
where:

**geo_start_point, geo_point2**

Fixed length alphanumeric, large enough to hold the JSON describing the point (for example, A200).

Is the starting point for which you want to calculate the drive route.

**Note:** You can generate a geometry point using the GIS_POINT function.

**geo_end_point, geo_point2**

Fixed length alphanumeric, large enough to hold the JSON describing the point (for example, A200).

Is the ending point for which you want to calculate the drive route.

**Note:** You can generate a geometry point using the GIS_POINT function.

The format of the field to which the drive route will be returned is TX.

**Example:** **Calculating the Drive Route Between Two Geometry Points**

The following uses a citibike .csv file that contains station names, latitudes and longitudes, and trip start times and end times. It uses the GIS_POINT function to define geometry points for start stations and end stations. It then uses GIS_DRIVE_ROUTE to calculate the route to get from the end point to the start point.

```sql
DEFINE FILE esri/esri-citibike
STARTPOINT/A200 = GIS_POINT('4326', START_STATION_LONGITUDE, START_STATION_LATITUDE);
ENDPOINT/A200 = GIS_POINT('4326', END_STATION_LONGITUDE, END_STATION_LATITUDE);
Route/TX140 (GEOGRAPHIC_ROLE=GEOMETRY_LINE) = GIS_DRIVE_ROUTE(ENDPOINT, STARTPOINT);
END
TABLE FILE esri/esri-citibike
PRINT START_STATION_NAME AS Start END_STATION_NAME AS End Route
WHERE START_STATION_ID EQ 147
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
TYPE=REPORT, GRID=OFF, SIZE-11,$
ENDSTYLE
END
```
GIS_GEOCODE_ADDR: Geocoding a Complete Address

GIS_GEOCODE_ADDR uses a GIS geocoding service to obtain the geometry point for a complete address.

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:**

```plaintext
GIS_GEOCODE_ADDR(address[, country])
```

**where:**

- **address**
  - Fixed length alphanumeric
  - Is the complete address to be geocoded.
**country**

Fixed length alphanumeric

Is a country name, which is optional if the country is the United States.

**Example:** Geocoding a Complete Address

The following request creates a complete address by concatenating the street address, city, state, and ZIP code. It then uses GIS_GEOCODE_ADDR to create a GIS point for the address.

```plaintext
DEFINE FILE WF_RETAIL_LITE
GADDRESS/A200 = ADDRESS_LINE_1 || ' ' || CITY_NAME || ' ' || STATE_PROV_NAME || ' ' || POSTAL_CODE;
GEOCODE1/A200 = GIS_GEOCODE_ADDR(GADDRESS);
END

TABLE FILE WF_RETAIL_LITE
PRINT ADDRESS_LINE_1 AS Address GEOCODE1
BY POSTAL_CODE AS Zip
WHERE CITY_NAME EQ 'New York'
WHERE POSTAL_CODE FROM '10013' TO '10020'
ON TABLE SET PAGE NOPAGE
END
```

The output is shown in the following image.

<table>

**GIS_GEOCODE_ADDR_CITY:** Geocoding an Address Line, City, and State

GIS_GEOCODE_ADDR_CITY uses a GIS geocoding service to obtain the geometry point for an address line, city, state, and optional country. The returned value is a fixed length alphanumeric format, large enough to hold the JSON describing the geographic location (for example, A200).
**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:**

**How to Geocode an Address Line, City, and State**

`GIS_GEOCODE_ADDR_CITY(street_addr, city, state [, country])`

where:

- `street_addr`  
  Fixed length alphanumeric  
  Is the street address to be geocoded.

- `city`  
  Fixed length alphanumeric  
  Is the city name associated with the street address.

- `state`  
  Fixed length alphanumeric  
  Is the state name associated with the street address.

- `country`  
  Fixed length alphanumeric  
  Is a country name, which is optional if the country is the United States.

**Example:**

**Geocoding a Street Address, City, and State**

The following request geocodes a street address using `GIS_GEOCODE_ADDR_CITY`.

```plaintext
DEFINE FILE WF_RETAIL_LITE
GEOCODE1/A200 = GIS_GEOCODE_ADDR_CITY(ADDRESS_LINE_1, CITY_NAME , STATE_PROV_NAME);
END

TABLE FILE WF_RETAIL_LITE
PRINT ADDRESS_LINE_1 AS Address GEOCODE1
BY POSTAL_CODE AS Zip
WHERE CITY_NAME EQ 'New York'
WHERE POSTAL_CODE FROM '10013' TO '10020'
ON TABLE SET PAGE NOPAGE
END
```
GIS_GEOCODE_ADDR_POSTAL: Geocoding an Address Line and Postal Code

GIS_GEOCODE_ADDR_POSTAL uses a GIS geocoding service to obtain the geometry point for an address line, postal code and optional country. The returned value is a fixed length alphanumeric format, large enough to hold the JSON describing the geographic location (for example, A200).

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:**

```
GIS_GEOCODE_ADDR_POSTAL( street_addr, postal_code [, country])
```

where:

- **street_addr**
  
  fixed length alphanumeric
  
  Is the street address to be geocoded.

- **postal_code**
  
  fixed length alphanumeric
  
  Is the postal code associated with the street address.

- **country**
  
  fixed length alphanumeric
  
  Is a country name, which is optional if the country is the United States.
GIS_GEOMETRY: Building a JSON Geometry Object

The GIS_GEOMETRY function builds a JSON Geometry object given a geometry type, WKID, and a geometry.

Syntax: How to Build a JSON Geometry Object

GIS_GEOMETRY(geotype, wkid, geometry)

where:

geotype

Alphanumeric

Is a geometry type, for example, 'esriGeometryPolygon', 'esriGeometryPolyline', 'esriGeometryMultipoint', 'EsriGeometryPoint', 'EsriGeometryExtent'...
**wkid**

Alphanumeric

Is a valid spatial reference ID. WKID is an abbreviation for Well-Known ID, which identifies a projected or geographic coordinate system.

**geometry**

TX

A geometry in JSON.

The output is returned as TX.

**Example: Building a JSON Geometry Object**

The following request builds a polygon geometry of the area encompassing ZIP code 10036 in Manhattan. The input geometry object is stored in a text (.ftm) file that is cross-referenced in the esri-citibike Master File. The field containing the geometry object is GEOMETRY.

```plaintext
DEFINE FILE esri/esri-citibike
WKID/A10 = '4326';
MASTER_GEOMETRY/TX256 (GEOGRAPHIC_ROLE=GEOMETRY_AREA) =
   GIS_GEOMETRY( 'esriGeometryPolygon', WKID , GEOMETRY );
END
TABLE FILE esri/esri-citibike
PRINT
   START_STATION_NAME AS Station
   START_STATION_LATITUDE AS Latitude
   START_STATION_LONGITUDE AS Longitude
   MASTER_GEOMETRY AS 'JSON Geometry Object'
WHERE START_STATION_ID EQ 479
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
type=report, grid=off, size=10,$
ENDSTYLE
END
```
GIS_IN_POLYGON: Determining if a Point is in a Complex Polygon

Given a point and a polygon definition, the GIS_IN_POLYGON function returns the value 1 (TRUE) if the point is in the polygon or 0 (FALSE) if the point is not in the polygon. The value is returned in integer format.

Syntax:

```
GIS_IN_POLYGON(point, polygon_definition)
```

where:

- **point**
  - Alphanumeric or text
  - Is the geometry point.

- **polygon_definition**
  - Text
  - Is the geometry area (polygon) definition.

The output is shown in the following image.
**Example:** Determining if a Point is in a Polygon

The following example determines if a station is inside ZIP code 10036. GIS_IN_POLYGON returns 1 for a point inside the polygon definition and 0 for a point outside. The polygon definition being passed is the same one used in the example for the GIS_GEOMETRY function described previously and defines the polygon for ZIP code 10036 in Manhattan in New York City. The value 1 is translated to Yes and 0 to No for display on the output.

```plaintext
DEFINE FILE esri/esri-citibike
WKID/A10 = '4326';
MASTER_GEOMETRY/TX256 (GEOGRAPHIC_ROLE=GEOMETRY_AREA) =
  GIS_GEOMETRY('esriGeometryPolygon', WKID, GEOMETRY);
START_STATION_POINT/A200=GIS_POINT(WKID, START_STATION_LONGITUDE,
START_STATION_LATITUDE);
STATION_IN_POLYGON/I4=GIS_IN_POLYGON(START_STATION_POINT, MASTER_GEOMETRY);
IN_POLYGON/A5 = IF STATION_IN_POLYGON EQ 1 THEN 'Yes' ELSE 'No';
END
TABLE FILE esri/esri-citibike
PRINT
  START_STATION_NAME AS Station
  IN_POLYGON AS 'Station in zip, code 10036?'
BY START_STATION_ID AS 'Station ID'
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
type=report, grid=off, size=10,$
type=data, column=in_polygon, style=bold, color=red, when = in_polygon eq
  'Yes','$
ENDSTYLE
END
```
GIS_LINE: Building a JSON Line

The output is shown in the following image.

<table>
<thead>
<tr>
<th>Station ID</th>

</tbody>
</table>

GIS_LINE: Building a JSON Line

Given two geometry points or lines, GIS_LINE builds a JSON line. The output is returned in text format.

Syntax: How to Build a JSON Line

GIS_LINE(geometry1, geometry2)

where:

geometry1
Alphanumeric or text

Is the first point or line for defining the beginning of the new line.
Alphanumeric or text

Is the second point or line for the concatenation of the new line.

**Example:** Building a JSON Line

The following request prints start stations and end stations and builds a JSON line between them.

```plaintext
DEFINE FILE ESRI/ESRI-CITIBIKE
STARTPOINT/A200 = GIS_POINT('4326', START_STATION_LONGITUDE,
START_STATION_LATITUDE);
ENDPOINT/A200 = GIS_POINT('4326', END_STATION_LONGITUDE,
END_STATION_LATITUDE);
CONNECTION_LINE/TX80 (GEOGRAPHIC_ROLE=GEOMETRY_LINE) =
  GIS_LINE(STARTPOINT, ENDPOINT);
END
TABLE FILE ESRI/ESRI-CITIBIKE
PRINT END_STATION_NAME AS End CONNECTION_LINE AS 'Connecting Line'
BY START_STATION_NAME AS Start
WHERE START_STATION_NAME LE 'D'
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
TYPE=REPORT, GRID=OFF,$
ENDSTYLE
END
```
**GIS_POINT: Building a Geometry Point**

Given a WKID (Well-Known ID) spatial reference, longitude, and latitude, the GIS_POINT function builds a JSON point defining a Geometry object with the provided WKID, longitude, and latitude. The function is optimized for those SQL engines that can build a JSON geometry object.

The field to which the point is returned should have fixed length alphanumeric format, large enough to hold the JSON describing the point (for example, A200).

**Syntax:**

**How to Build a Geometry Point**

GIS_POINT(wkid, longitude, latitude)

where:

**wkid**

Fixed length alphanumeric

Is a spatial reference code (WKID). WKID is an abbreviation for Well-Known ID, which identifies a projected or geographic coordinate system.
longitude
D20.8
Is the longitude for the point.

latitude
D20.8
Is the latitude for the point.

Example: Building a Geometry Point

The following request uses the spatial reference code 4326 (decimal degrees) and state capital longitudes and latitudes to build a geometry point.

```
DEFINE FILE WF_RETAIL_LITE
GPOINT/A200 = GIS_POINT('4326', STATE_PROV_CAPITAL_LONGITUDE,
STATE_PROV_CAPITAL_LATITUDE);
END
```

```
TABLE FILE WF_RETAIL_LITE
SUM FST.STATE_PROV_CAPITAL_LONGITUDE AS Longitude
FST.STATE_PROV_CAPITAL_LATITUDE AS Latitude
FST.GPOINT AS Point
BY STATE_PROV_CAPITAL_NAME AS Capital
WHERE COUNTRY_NAME EQ 'United States'
WHERE STATE_PROV_CAPITAL_NAME LT 'C'
ON TABLE SET PAGE NOPAGE
END
```

The output is shown in the following image.

<table>
<thead>
<tr>
<th>Capital</th>
<th>Longitude</th>
<th>Latitude</th>
<th>Point</th>

</table>
GIS_REVERSE_COORDINATE: Returning a Geographic Component

Given longitude and latitude values and the name of a geographic component, GIS_REVERSE_COORDINATE returns the specified geographic component values associated with those coordinates.

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:** How to Return a Geographic Component

```plaintext
GIS_REVERSE_COORDINATE(longitude, latitude, component)
```

where:

- **longitude**
  - Numeric
  - Is the longitude of the component to return.

- **latitude**
  - Numeric
  - Is the latitude of the component to return.

- **component**
  - Keyword
  - Is one of the following components:
    - MATCH_ADDRESS, which returns the matching address.
    - METROAREA, which returns the metro area name.
    - REGION, which returns the region name.
    - SUBREGION, which returns the subregion name.
    - CITY, which returns the city name.
    - POSTAL, which returns the postal code.

The value is returned as text and can be assigned to a field with text or alphanumeric (fixed or variable length) format.

**Example:** Returning Geographic Components Associated With Coordinates

GIS_REVERSE_COORDINATE returns the REGION, given a city longitude and city latitude.

```plaintext
GIS_REVERSE_COORDINATE(CITY_LONGITUDE, CITY_LATITUDE, REGION)
```
For Annapolis, the result is Maryland.

For Baton Rouge, the result is Louisiana.

**GIS_SERVICE_AREA: Calculating a Geometry Area Around a Given Point**

The GIS_SERVICE_AREA function uses a GIS service to calculate the geometry area with access boundaries within the given time or distance from the provided geometry point. The output is returned in text format.

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:** How to Calculate a Geometry Area Around a Point

```
GIS_SERVICE_AREA(geo_point, distance, travel_mode)
```

where:

- **geo_point**
  Alphanumeric
  
  Is the starting geometry point.

- **distance**
  Alphanumeric
  
  Is the travel limitation in either time or distance units.

- **travel_mode**
  Alphanumeric
  
  Is a valid travel mode as defined in gis_serv_area.mas in the Catalog directory under the server installation directory. The accepted travel modes are;

  - 'Miles'. This is the default value.
  - 'TravelTime'.
  - 'TruckTravelTime'.
  - 'WalkTime'.
  - 'Kilometers'.
Example: Calculating a Service Area Around a Geometry Point

The following request calculates the geometry area that is a five-minute walk around a station.

```
DEFINE FILE esri/esri-citibike
WKID/A10='4326';
START_STATION_POINT/A200=GIS_POINT(WKID, START_STATION_LONGITUDE, START_STATION_LATITUDE);
DISTANCE/A10='5';
TRAVEL_MODE/A10='WalkTime';
STATION_SERVICE_AREA/TX80 (GEOGRAPHIC_ROLE=GEOMETRY_AREA)=GIS_SERVICE_AREA(START_STATION_POINT, DISTANCE, TRAVEL_MODE);
END
TABLE FILE esri/esri-citibike
PRINT
  START_STATION_ID AS 'Station ID'
  START_STATION_NAME AS 'Station Name'
  STATION_SERVICE_AREA AS '5-Minute Walk Service Area Around Station'
WHERE START_STATION_ID EQ 479 OR 512;
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
  TYPE=REPORT, GRID=OFF, SIZE=12,$
ENDSTYLE
END
```
The GIS_SERV_AREA_XY function uses a GIS service to calculate the geometry area with access boundaries within the given time or distance from the provided coordinate. The output is returned in text format.

**Note:** This function uses GIS services and requires an Esri ArcGIS adapter connection with named credentials.

**Syntax:**

```plaintext
GIS_SERV_AREA_XY(longitude, latitude, distance, travel_mode[, wkid])
```
where:

**longitude**
Alphanumeric
Is the longitude of the starting point.

**latitude**
Alphanumeric
Is the latitude of the starting point.

**distance**
Integer
Is the travel limitation in either time or distance units.

**travel_mode**
Alphanumeric
Is a valid travel mode as defined in gis_serv_area.mas in the Catalog directory under the server installation directory. The accepted travel modes are;

- 'Miles'. This is the default value.
- 'TravelTime'.
- 'TruckTravelTime'.
- 'WalkTime'.
- 'Kilometers'.

**wkid**
Alphanumeric
Is the spatial reference ID for the coordinate. WKID is an abbreviation for Well-Known ID, which identifies a projected or geographic coordinate system. The default value is '4326', which represents decimal degrees.
**Example:** Calculating a Service Area Around a Coordinate

The following request calculates the geometry area that is a five-minute walk around a station, using the longitude and latitude that specify the station location.

```
DEFINE FILE esri/esri-citibike
DISTANCE/I4=5;
WKID/A10='4326';
TRAVEL_MODE/A10='WalkTime';
STATION_SERVICE_AREA/TX80 (GEOGRAPHIC_ROLE=GEOMETRY_AREA)=
   GIS_SERV_AREA_XY(START_STATION_LONGITUDE, START_STATION_LATITUDE, 
   DISTANCE, TRAVEL_MODE, WKID);
END
TABLE FILE esri/esri-citibike
PRINT
   START_STATION_ID AS 'Station ID'
   START_STATION_NAME AS 'Station Name'
   STATION_SERVICE_AREA
      AS '5-Minute Walk Service Area Around Station Coordinate'
WHERE START_STATION_ID EQ 479 OR 512;
ON TABLE SET PAGE NOLEAD
ON TABLE SET STYLE *
   TYPE=REPORT, GRID=OFF, SIZE=12, $
ENDSTYLE
END
```

The output is shown in the following image.

<table>
<thead>
<tr>
<th>Station ID</th>
<th>Station Name</th>
<th>5-Minute Walk Area Around Station Coordinate</th>
</tr>
</thead>
<tbody>
<tr>
<td>512</td>
<td>W 29 St &amp; 9 Ave</td>
<td></td>
</tr>
<tr>
<td>479</td>
<td>9 Ave &amp; W 45 St</td>
<td></td>
</tr>
</tbody>
</table>

The output is shown in the following image.
SQL character functions manipulate alphanumeric fields and character strings.

In this chapter:

- CHAR_LENGTH: Finding the Length of a Character String
- CONCAT: Concatenating Two Character Strings
- DIGITS: Converting a Numeric Value to a Character String
- EDIT: Editing a Value According to a Format (SQL)
- LCASE: Converting a Character String to Lowercase
- LTRIM: Removing Leading Spaces
- POSITION: Finding the Position of a Substring
- RTRIM: Removing Trailing Spaces
- SUBSTR: Extracting a Substring From a String Value (SQL)
- TRIM: Removing Leading or Trailing Characters (SQL)
- UCASE: Converting a Character String to Uppercase
- VARGRAPHIC: Converting to Double-byte Character Data

CHAR_LENGTH: Finding the Length of a Character String

The CHAR_LENGTH function returns the length of a character string. CHARACTER_LENGTH is identical to CHAR_LENGTH.

This function is most useful for columns described as VARCHAR (variable length character). For example, if a column described as GLOSS VARCHAR(10) contains

'bryllig'
'slythy '
'toves '

then CHAR_LENGTH(GLOSS) would return
If the column is described as CHAR (non-variable length character), the same number is returned for all rows. In this case, CHAR_LENGTH(GLOSS) would return

To avoid counting trailing blanks use CHAR_LENGTH(TRIM (TRAILING FROM GLOSS)). See TRIM: Removing Leading or Trailing Characters (SQL) on page 380 for details.

**Syntax:** How to Find the Length of a Character String

\[
\text{CHAR_LENGTH}(\text{arg})
\]

where:

- \( \text{arg} \)
  - Character string
  - Is the value whose length is to be determined.

This function returns an integer value.

**Example:** Finding the Length of a Character String

CHAR_LENGTH finds the length of the string. This example,

\[
\text{CHAR_LENGTH}(\text{"abcdef"})
\]

returns 6.

This example,

\[
\text{CHAR_LENGTH}(\text{"abcdef   "})
\]

returns 9, since trailing blanks are counted.

**CONCAT: Concatenating Two Character Strings**

The CONCAT function concatenates the values of two arguments. The result is a character string consisting of the characters of the first argument followed by the characters of the second argument.
### Syntax:  How to Concatenate Two Character Strings

`CONCAT(arg1, arg2)`

where:

`arg1, arg2`

Character strings

Are the strings to be concatenated.

The length of the result is the sum of the lengths of the two arguments. If either argument is variable-length, so is the result; otherwise, the result is fixed-length.

#### Example:  Concatenating Two Character Strings

`CONCAT` concatenates two string. This example,

```
CONCAT('abc', 'def')
```

returns `abcdef`.

### DIGITS: Converting a Numeric Value to a Character String

The `DIGITS` function extracts the digits of a decimal or integer value into a character string. The sign and decimal point of the number (if present) are ignored.

### Syntax:  How to Convert a Numeric Value to a Character String

`DIGITS(arg)`

where:

`arg`

Numeric (decimal or integer, not floating-point)

Is the numeric value.

The length of the resulting string is determined by the precision of the argument.

#### Example:  Converting a Numeric Value to a Character String

`DIGITS` converts a numeric value to a character string. This example,

```
DIGITS(-444.321)
```

returns `0000444321`. 
EDIT: Editing a Value According to a Format (SQL)

The EDIT function edits a numeric or character value according to a format specified by a mask. (It works exactly like the EDIT function in FOCUS.)

A 9 in the mask indicates the corresponding character in the source value is copied into the result. A $ in the mask indicates that the corresponding character is to be ignored. Any other character is inserted into the result.

Syntax: How to Edit a Value According to a Format

```
EDIT(arg, mask)
```

where:

- **arg**
  - Numeric or character string
  - Is the value to be edited.

- **mask**
  - character string
  - Indicates how the editing is to proceed.

This function returns a character string whose length is determined by the mask.

Example: Editing a Value According to a Format

EDIT extracts a character from a string. This example,

```
EDIT('FRED', '9$$$')
```

returns F.

This example,

```
EDIT('123456789', '999-99-9999')
```

returns 123-45-6789.

LCASE: Converting a Character String to Lowercase

The LCASE function converts a character string value to lowercase. That is, capital letters are replaced by their corresponding lowercase values.

LOWER and LOWERCASE are identical to LCASE.
**Syntax:** How to Convert a Character String to Lowercase

\[ \text{LCASE}(\text{arg}) \]

where:

\[ \text{arg} \]

Character string

Is the value to be converted to lowercase.

This function returns a varying character string. The length is the same as the input argument.

**Example:** Converting a Character String to Lowercase

LCASE converts a character string to lowercase. This example,

\[ \text{LCASE('XYZ')} \]

returns xyz.

**LTRIM: Removing Leading Spaces**

The LTRIM function removes leading spaces from a character string.

**Syntax:** How to Remove Leading Spaces

\[ \text{LTRIM}(\text{arg}) \]

where:

\[ \text{arg} \]

character string

Is the value to be trimmed.

This function returns a varying character string. The data type of the result has a length equal to that of the input argument (although the value may be shorter).

**Example:** Removing Leading Spaces

LTRIM removes leading spaces. This example,

\[ \text{LTRIM('   ABC   ')} \]

returns 'ABC   '.
POSITION: Finding the Position of a Substring

The POSITION function returns the position within a character string of a specified substring. If the substring does not appear in the character string, the result is 0. Otherwise, the value returned is one greater than the number of characters in the string preceding the start of the first occurrence of the substring.

Syntax: How to Find the Position of a Substring

\[
\text{POSITION}(\text{substring} \ \text{IN} \ \text{arg})
\]

where:

- **substring**
  - character string
  - Is the substring to search for.

- **arg**
  - character string
  - Is the string to be searched for the substring.

This function returns an integer value.

Example: Finding the Position of a Substring

POSITION returns the position of a substring. This example,

\[
\text{POSITION ('A' \ \text{IN} \ 'AEIOU')}
\]

returns 1.

This example,

\[
\text{POSITION ('IOU' \ \text{IN} \ 'AEIOU')}
\]

returns 3.

This example,

\[
\text{POSITION ('Y' \ \text{IN} \ 'AEIOU')}
\]

returns 0.

RTRIM: Removing Trailing Spaces

The RTRIM function removes trailing spaces from a character string.
Syntax: How to Remove Trailing Spaces

RTRIM(arg)

where:
arg
character string
Is the value to be trimmed.

This function returns a varying character string. The data type of the result has a length equal to that of the input argument (although the value may be shorter).

Example: Removing Trailing Spaces

RTRIM removes trailing spaces. This example,

RTRIM('   ABC   ')

returns ' ABC'.

SUBSTR: Extracting a Substring From a String Value (SQL)

The SUBSTR function returns a substring of a character value. You specify the start position of the substring within the value. You can also specify the length of the substring (if omitted, the substring extends from the start position to the end of the string value). If the specified length value is longer than the input string, the result is the full input string.

SUBSTRING is identical to SUBSTR.

Syntax: How to Extract a Substring From a String Value

SUBSTR(arg FROM start-pos [FOR length])

or

SUBSTR(arg, start-pos [, length])

where:
arg
character string
Is the field containing the parent character string.

start-pos
Integer
Is the position within arg at which the substring begins.

length
  Integer
  If present, is the length of the substring. This function returns a varying character string. The data type of the result has a length equal to that of the input argument (although the value may be shorter).

**Example:** Extracting a Substring From a String Value

SUBSTR function returns a substring. This example,

```
SUBSTR('ABC' FROM 2)
```

Returns BC.

This example,

```
SUBSTRING('ABC' FROM 1 FOR 2)
```

returns AB.

This example,

```
SUBSTR('ABC', 10)
```

returns ABC.

**TRIM: Removing Leading or Trailing Characters (SQL)**

The TRIM function removes leading and/or trailing characters from a character string. The character to be removed may be specified. If no character is specified, the space character is assumed. Whether to remove leading and/or trailing characters may be specified. Without this specification, both leading and trailing appearances of the specified character are removed.

**Syntax:** How to Remove Leading or Trailing Characters

```
TRIM(arg)
TRIM(trim-where [trim-char] FROM arg)
TRIM(trim-char FROM arg)
```

where:

```
arg
```

classifier string
  Is the source string value to be trimmed.
**trim-where**

Value may be LEADING, TRAILING or BOTH. Indicates where characters will be removed. If not specified, BOTH is assumed.

**trim-char**

character string

Is the character to be removed. If not specified, the space character is assumed.

This function returns a varying character string. The data type of the result has a length equal to that of the input argument (although the value may be shorter).

**Example:** Removing Leading or Trailing Characters

TRIM removes leading and/or trailing characters. This example,

```
TRIM(' ABC ')
```

returns ABC.

This example,

```
TRIM(LEADING FROM ' ABC ')
```

returns 'ABC '.

This example,

```
TRIM(TRAILING FROM ' ABC ')
```

```
TRIM(BOTH 'X' FROM 'XXYYYYXX') = ('YYY')
```

returns ' ABC'

This example,

```
TRIM(BOTH 'X' FROM 'XXYYYYXX')
```

returns YYY.

**UCASE: Converting a Character String to Uppercase**

The UCASE function converts a character string value to uppercase. That is, lowercase letters are replaced by their corresponding uppercase values. UPPER and UPPERCASE are identical to UCASE.

**Syntax:** How to Convert a Character String to Uppercase

```ucase
UCASE(arg)
```
where:

\textit{arg}

character string

Is the value to be converted to uppercase.

This function returns a character string whose length is the same as that of the input argument.

\textbf{Example: Converting a Character String to Uppercase}

UCASE converts a character string value to uppercase. This example, \texttt{UCASE('abc')}

returns ABC.

\textbf{VARGRAPHIC: Converting to Double-byte Character Data}

The VARGRAPHIC function converts the input value to double-byte character data

\textbf{Syntax: How to Convert to the Double-byte Character Format}

\texttt{VARGRAPHIC arg}

where:

\textit{arg}

character, graphic, or date

Is the input value.

\textbf{Note:} This function can only be used for DB2 and can only be used with Direct or Automatic Passthru. This function returns the value in double-byte character format.
Chapter 20

SQL Date and Time Functions

SQL date and time functions perform manipulations on date and time values.

In this chapter:

- **CURRENT_DATE**: Obtaining the Date
- **CURRENT_TIME**: Obtaining the Time
- **CURRENT_TIMESTAMP**: Obtaining the Timestamp (Date/Time)
- **DAY**: Obtaining the Day of the Month From a Date/Timestamp
- **DAYS**: Obtaining the Number of Days Since January 1, 0001
- **EXTRACT**: Obtaining a Datetime Field From Date/Time/Timestamp
- **HOUR**: Obtaining the Hour From Time/Timestamp
- **MICROSECOND**: Obtaining Microseconds From Time/Timestamp
- **MILLISECOND**: Obtaining Milliseconds From Time/Timestamp
- **MINUTE**: Obtaining the Minute From Time/Timestamp
- **MONTH**: Obtaining the Month From Date/Timestamp
- **SECOND**: Obtaining the Second Field From Time/Timestamp
- **QUARTER**: Returning the Quarter of the Year
- **WEEKDAY**: Returning the Day of the Week
- **YEAR**: Obtaining the Year From a Date or Timestamp

**CURRENT_DATE**: Obtaining the Date

The **CURRENT_DATE** function returns the current date of the operating system in the form YYYYMMDD.

**Syntax:**

To obtain the current date:

```sql
CURRENT_DATE
```

This function returns the date in YYMD format.
Example: Obtaining the Current Date

On August 18, 2005, CURRENT_DATE will return 20050818.

CURRENT_TIME: Obtaining the Time

The CURRENT_TIME function returns the current time of the operating system in the form HHMMSS. You may specify the number of decimal places for fractions of a second—0, 3, or 6 places. Zero (0) places is the default.

Syntax: How to Obtain the Current Time

```sql
CURRENT_TIME[(precision)]
```

where:

- `precision` Integer constant
  - Is the number of decimal places for fractions of a second. Possible values are 0, 3, and 6.

This function returns the time (format: HHIS if no decimal places; HHISs if 3 decimal places; HHISsm if 6 decimal places).

Example: Obtaining the Current Time

At exactly half past 11 AM:

CURRENT_TIME returns 113000.

CURRENT_TIME(3) returns 113000000.

CURRENT_TIME(6) returns 113000000000.

CURRENT_TIMESTAMP: Obtaining the Timestamp (Date/Time)

The CURRENT_TIMESTAMP function returns the current timestamp of the operating system (date and time) in the form YYYYMMDDHHMMSS. You may specify the number of decimal places for fractions of a second—0, 3, or 6 places. Six (6) places is the default.

Syntax: How to Obtain the Current Timestamp

```sql
CURRENT_TIMESTAMP[(precision)]
```

where:

- `precision` Integer constant
Is the number of decimal places for fractions of a second. Possible values are 0, 3, and 6. This function returns a timestamp (format: HYYMDS if no decimal places; HYYMDs if 3 decimal places; HYYMDm if 6 decimal places).

**Example:** Obtaining the Current Timestamp

At 2:11:23 PM on October 9, 2005:

- CURRENT_TIMESTAMP returns 20051009141123000000.
- CURRENT_TIMESTAMP(0) returns 20051009141123.
- CURRENT_TIMESTAMP(3) returns 20051009141123000.
- CURRENT_TIMESTAMP(6) returns 20051009141123000000.

**DAY: Obtaining the Day of the Month From a Date/Timestamp**

The DAY function returns the day of the month from a date or timestamp value.

**Syntax:**

How to Obtain the Day of the Month From a Date or Timestamp

\[ \text{DAY}(\text{arg}) \]

where:

\[ \text{arg} \]

- Date or timestamp
- Is the input value.

This function returns an integer value.

**Example:** Obtaining the Day of the Month From a Date or Timestamp

DAY returns the day of the month from a date or timestamp. This example,

\[ \text{DAY('1976-07-04')} \]

returns 4.

This example,

\[ \text{DAY('2001-01-22 10:00:00')} \]

returns 22.
DAYS: Obtaining the Number of Days Since January 1, 0001

The DAYS function returns 1 more than the number of days from January 1, 0001 to the provided date value.

Syntax:  How to Obtain the Number of Days Since January 1, 1900

\[ \text{DAYS}(\text{arg}) \]

where:

\[ \text{arg} \]

Date or timestamp

Is the input argument.

This function returns an integer value.

Example:  Obtaining the Number of Days Since January 1, 1900

DAYS returns one more than the number of days since January 1, 1900.

\[ \text{DAYS}(\text{’2000-01-01’}) \]

returns 730120.

EXTRACT: Obtaining a Datetime Field From Date/Time/Timestamp

The EXTRACT function can be used to obtain the year, month, day of month, hour, minute, second, millisecond, or microsecond component of a date, time, or timestamp value.

Syntax:  How to Obtain a Datetime Field From a Date, Time, or Timestamp

\[ \text{EXTRACT}(\text{field FROM } \text{arg}) \]

where:

\[ \text{arg} \]

Date, time, or timestamp

Is the input argument.

\[ \text{field} \]

Is the datetime field of interest. Possible values are YEAR, QUARTER, MONTH, DAY, WEEKDAY, HOUR, MINUTE, SECOND, MILLISECOND and MICROSECOND.

This function returns an integer value.
Note:

- YEAR, QUARTER, MONTH, DAY, and WEEKDAY can be used only if the argument is date or timestamp.
- HOUR, MINUTE, SECOND, MILLISECOND and MICROSECOND can be used only if the argument is time or timestamp.

Example: Obtaining a Datetime Field From a Date, Time, or Timestamp
EXTRACT returns the components of a date, time, or timestamp. This example,

`EXTRACT(YEAR FROM '2000-01-01')`

returns 2000.

This example,

`EXTRACT(HOUR FROM '11:22:33')`

returns 11.

This example,

`EXTRACT(MICROSECOND FROM '2000-01-01 11:22:33.456789')`

returns 456,789.

HOUR: Obtaining the Hour From Time/Timestamp

The HOUR function returns the hour field from a time or timestamp value.

Syntax: How to Obtain the Hour From a Time or Timestamp

`HOUR(arg)`

where:

`arg`

Time or timestamp

Is the input value.

This function returns an integer value.
Example: Obtaining the Hour From a Time or Timestamp

HOUR returns the hour from a time or timestamp. This example,

```
HOUR('11:22:33')
```

returns 11.

This example,

```
HOUR('2001-01-22 10:00:00')
```

returns 10.

MICROSECOND: Obtaining Microseconds From Time/Timestamp

The MICROSECOND function returns the number of microseconds from a time or timestamp value.

Syntax: How to Obtain the Number of Microseconds From a Time or Timestamp

```
MICROSECOND(arg)
```

where:

```
arg
```

Time or timestamp

Is the input value.

This function returns an integer value.

Example: Obtaining the Number of Microseconds From a Time or Timestamp

MICROSECOND returns the microseconds from a time or timestamp. This example,

```
MICROSECOND('11:22:33.456789')
```

returns 456,789.

This example,

```
MICROSECOND('2001-01-22 10:00:00')
```

returns 0.
MILLISECOND: Obtaining Milliseconds From Time/Timestamp

The MILLISECOND function returns the number of milliseconds from a time or timestamp value.

**Syntax:**

How to Obtain the Number of Milliseconds From a Time or Timestamp

\[
\text{MILLISECOND} (\text{arg})
\]

where:

\[
\text{arg}\]  
Time or timestamp  
Is the input value.

This function returns an integer value.

**Example:**

Obtaining the Number of Milliseconds From a Time or Timestamp

MILLISECOND returns the number of milliseconds from a time or timestamp. This example,

\[
\text{MILLISECOND ('11:22:33.456')}\]

returns 456.

This example,

\[
\text{MILLISECOND ('2001-01-22 10:11:12')}\]

returns 0.

MINUTE: Obtaining the Minute From Time/Timestamp

The MINUTE function returns the number of minutes from a time or timestamp value.

**Syntax:**

How to Obtain the Minute From a Time or Timestamp

\[
\text{MINUTE} (\text{arg})
\]

where:

\[
\text{arg}\]  
Time or timestamp  
Is the input value.

This function returns an integer value.
Example: Obtaining the Minute From a Time or Timestamp

MINUTE returns the minutes from a time or timestamp. This example,

MINUTE('11:22:33')

returns 22.

This example,

MINUTE('2001-01-22 10:11:12')

returns 11.

MONTH: Obtaining the Month From Date/Timestamp

The MONTH function returns the month field from a date or timestamp value.

Syntax: How to Obtain the Month From a Date or Timestamp

MONTH(arg)

where:

arg

Date or timestamp

Is the input value.

This function returns an integer value.

Example: Obtaining the Month From a Date or Timestamp

MONTH returns the month from a date or timestamp. This example,

MONTH('1976-07-04')

returns 7.

This example,

MONTH('2001-01-22 10:00:00')

returns 1.

SECOND: Obtaining the Second Field From Time/Timestamp

The SECOND function returns the second field from a time or timestamp value.
**Syntax:**

How to Obtain the Second Field From a Time or Timestamp

`SECOND(arg)`

where:

`arg`

Time or timestamp

Is the input value.

This function returns an integer value.

**Example:**

Obtaining the Second Field From a Time or Timestamp

SECOND returns seconds from a time or timestamp. This example,

`SECOND('11:22:33')`

returns 33.

This example,

`SECOND('2001-01-22 12:24:36')`

returns 36.

**QUARTER:** Returning the Quarter of the Year

Given a date or date-time value, QUARTER returns an integer (from 1 to 4) that represents the quarter within which that date falls.

**Syntax:**

How to Return the Quarter of the Year

`QUARTER(arg)`

where:

`arg`

Date or date-time

Is the input date or date-time value.

**Example:**

Returning the Quarter of the Year

QUARTER returns the quarter of the year for each date of birth:

`QUARTER(DATE_OF_BIRTH)`
For 1993/03/27, the result is 1.

**WEEKDAY: Returning the Day of the Week**

Given a date or date-time value, WEEKDAY returns an integer from 1 (Monday) to 7 (Sunday) representing the day of the week for that date.

**Syntax:**

How to Return the Day of the Week

\[
\text{WEEKDAY}(\text{arg})
\]

where:

\[
\begin{align*}
\text{arg} & \quad \text{Date or date-time} \\
& \quad \text{Is the input date or date-time value.}
\end{align*}
\]

**Example:**

Returning the Day of the Week

WEEKDAY returns the day of the week for each birth date, where 1 represents Monday and 7 represents Sunday:

\[
\text{WEEKDAY(DATE_OF_BIRTH)}
\]

For 1993/03/27, the result is 6 (Saturday).

**YEAR: Obtaining the Year From a Date or Timestamp**

The YEAR function returns the year field from a date or timestamp value.

**Syntax:**

How to Obtain the Year From a Date or Timestamp

\[
\text{YEAR}(\text{arg})
\]

where:

\[
\begin{align*}
\text{arg} & \quad \text{Date or timestamp} \\
& \quad \text{Is the input value.}
\end{align*}
\]

This function returns an integer value.
Example: Obtaining the Year From a Date or Timestamp

YEAR returns the year from a date or timestamp value. This example,

```sql
YEAR('1976-07-04')
```

returns 1976.

This example,

```sql
YEAR('2001-01-22 10:00:00')
```

SQL data type conversion functions convert fields from one data type to another.

In this chapter:

- **CAST**: Converting to a Specific Data Type
- **CHAR**: Converting to a Character String
- **CHAR**: Converting to a Standard Date-Time Format
- **DATE**: Converting to a Date
- **DECIMAL**: Converting to Decimal Format
- **FLOAT**: Converting to Floating Point Format
- **INT**: Converting to an Integer
- **SMALLINT**: Converting to a Small Integer
- **TIME**: Converting to a Time
- **TIMESTAMP**: Converting to a Timestamp

### CAST: Converting to a Specific Data Type

The CAST function converts the value of its argument to a specified data type.

**Syntax:**

How to Convert to a Specific Data Type

```
CAST(expression AS data_type[(length)])
```

where:

- **arg**
  
  Any data type that can be converted to the result data type

  Is the value to be converted.

- **data-type**
  
  Is the result data type: CHARACTER, CHARACTER VARYING, NUMERIC, DECIMAL, INTEGER, SMALLINT, FLOAT, REAL, DOUBLE PRECISION, DATE, TIME or TIMESTAMP.
**length**

Is an optional parameter of character data types.

This function returns the input value converted to the specified data type.

**Example:**  **Converting to a Specific Data Type**

CAST converts a value to a specified data type. This example,

```
CAST(2.5 AS INTEGER)
```

returns 2.

This example,

```
CAST( '3.333' AS FLOAT)
```

returns 3.333.

**CHAR:** **Converting to a Character String**

There are two versions of the CHAR function, one for converting an argument to a character string, and one for converting a date, time, or timestamp value to a standard format. The version that takes one argument converts its argument to a character string. For information about using CHAR to convert a date, time, or timestamp value to a standard format, see **CHAR: Converting to a Standard Date-Time Format** on page 397.

**Syntax:**  **How to Convert to a Character String**

```
CHAR(arg)
```

where:

```
arg
```

Any type

Is the value to be converted.

This function returns a character string whose length is of sufficient size to hold the value.

**Example:**  **Converting to a Character String**

CHAR converts a value to a character string. This example,

```
CHAR(566.23)
```

returns 566.23.
CHAR: Converting to a Standard Date-Time Format

There are two versions of the CHAR function, one for converting an argument to a character string, and one for converting a date, time, or timestamp value to a standard format. The version that takes two arguments converts a date, time, or timestamp value to one of the standard date-time formats. For information about using CHAR to convert a single argument to a character string, see CHAR: Converting to a Character String on page 396.

Syntax: How to Convert a Date, Time, or Timestamp Value to a Standard Format

CHAR(datetime, fmt)

where:

datetime
Date

Is the date, time, or timestamp value to be converted.

fmt
Can be one of the following formats:

<table>
<thead>
<tr>
<th>Name of Standard</th>
<th>Date Format</th>
<th>Time Format</th>
<th>Timestamp Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO</td>
<td>yyyy-mm-dd</td>
<td>hh.mm.ss</td>
<td>yyyy-mm-dd hh:mm:ss.xxxxxx</td>
</tr>
<tr>
<td>USA</td>
<td>mm/dd/yyyy</td>
<td>hh.mm AM/PM</td>
<td>yyyy-mm-dd-hh.mm.ss.xxxxxx</td>
</tr>
<tr>
<td>EUR</td>
<td>dd.mm.yyyy</td>
<td>hh.mm.ss</td>
<td>yyyy-mm-dd-hh.mm.ss.xxxxxx</td>
</tr>
<tr>
<td>JIS</td>
<td>yyyy-mm-dd</td>
<td>hh:mm:ss</td>
<td>yyyy-mm-dd-hh.mm.ss.xxxxxx</td>
</tr>
</tbody>
</table>

This function returns a character string whose length is of sufficient size to hold the value.

Example: Converting Date and Time Values to Standard Formats

CHAR converts a date, time, or timestamp value to a standard format. The following examples use the constants CURRENT DATE, CURRENT TIME, and CURRENT TIMESTAMP. Assume the current date is November 17, 2011:

CHAR(CURRENT DATE, USA) returns 11/17/2011
CHAR(CURRENT DATE, ISO) returns 2011-11-17
CHAR (CURRENT TIME, USA) returns 03:45 PM
CHAR (CURRENT TIME, ISO) returns 15:45.00
CHAR (CURRENT TIMESTAMP, ISO) returns 2011-11-17 15:45:00

DATE: Converting to a Date

The DATE function converts its argument to a date. The type of the argument value may be character, date, or timestamp.

If the argument is:

- A character, its value must correctly represent a date; that date is the result.
- A date, its value is returned.
- A timestamp, the date portion of the timestamp value is returned.

Syntax: How to Convert to a Date

DATE(arg)

where:

arg

character string, date, or timestamp

Is the value to be converted.

The DATE function returns a date in YYMD format.

Example: Converting to a Date

DATE converts a value to a date. This example,

DATE('1999-03-29 14:39:30')

returns 19990329.

DECIMAL: Converting to Decimal Format

The DECIMAL function converts a number to fixed-length decimal format.
**Syntax:** How to Convert to the Decimal Format

```sql
DECIMAL(arg, [length [,dec-places]])
```

where:

- `arg`
  Numeric
  Is the input value.

- `length`
  Integer
  The maximum number of digits in the integer portion of the result. The default is 15.

- `dec-places`
  Integer
  Is the number of decimal places in the result. The default is the same number of decimal places as in the type of the argument.

This function returns a numeric value in fixed-length decimal format.

**Example:** Converting to Decimal Format

DECIMAL converts a number to fixed-length decimal format. This example,

```sql
DECIMAL(5.12345, 4, 2)
```

returns 5.12.

**FLOAT: Converting to Floating Point Format**

The FLOAT function converts a number to floating-point format.

**Syntax:** How to Convert to the Floating Point Format

```sql
FLOAT(arg)
```

where:

- `arg`
  Numeric
INT: Converting to an Integer

Is the input value.
This function returns the value in floating-point format.

Example: Converting to Floating Point Format
FLOAT converts a number to floating-point format. This example,
FLOAT(3)
returns 3.0.

INT: Converting to an Integer
The INT function converts a number to an integer. If the input value is not an integer, the result is truncated.
INTEGER is identical to INT.

Syntax: How to Convert to an Integer

INT(arg)

where:
arg
Numeric
Is the input value.
This function returns the number in integer format.

Example: Converting to an Integer
INT converts a number to an integer. This example,
INT(4.8)
returns 4.

SMALLINT: Converting to a Small Integer
The SMALLINT function converts a number to a small integer. Generally, a small integer occupies only two bytes in memory.

Syntax: How to Convert to a Small Integer

SMALLINT(arg)
where:

\( arg \)

Numeric

Is the input value.

This function returns the number in small integer format.

**Example:** Converting to a Small Integer

SMALLINT converts a number to a small integer. This example,

\( \text{SMALLINT}(3.5) \)

returns 3.

**TIME:** Converting to a Time

The TIME function converts its argument to a time. The type of the argument value may be character, time, or timestamp.

- If the argument is a character, its value must correctly represent a time; that time is the result.
- If the argument is a time, its value is returned.
- If the argument is a timestamp, the time portion of the timestamp value is returned.

**Syntax:** How to Convert to a Time

\[ \text{TIME}(arg) \]

where:

\( arg \)

character string, time, or timestamp

Is the input value.

This function returns a time.

**Example:** Converting to a Time

TIME converts a value argument to a time. This example,

\[ \text{TIME}('2004-03-15 01:02:03.444') \]
returns 010203444.

**TIMESTAMP: Converting to a Timestamp**

The `TIMESTAMP` function converts its argument to a timestamp. The argument type can be character, date, time, or timestamp.

- If the argument is a character, its value must correctly represent a timestamp; that timestamp is the result.
- If the argument is a date, the value of the result is the timestamp, with the date component equal to the argument and the time component equal to midnight.
- If the argument is a time, the value of the result is the timestamp, with the date component equal to the current date, and the time component equal to the argument.
- If the argument is a timestamp, its value is returned.

**Syntax:**

How to Convert to a Timestamp

```
TIMESTAMP(arg)
```

where:

- `arg`
  
  character string, date, time, or timestamp
  
  Is the input value.
  
This function returns a timestamp.

**Example:**

Converting to a Timestamp

`TIMESTAMP` converts a value to a timestamp. This example,

```
TIMESTAMP('2004-06-24')
```

returns 20040624000000.

This example,

```
TIMESTAMP('11:22:33')
```

returns 20010101112233, if the current date is January 1, 2001.
Chapter 22

SQL Numeric Functions

SQL numeric functions perform calculations on numeric constants and fields.

In this chapter:

- ABS: Returning an Absolute Value (SQL)
- CEIL: Returning the Smallest Integer Greater Than or Equal to a Value
- FLOOR: Returning the Largest Integer Less Than or Equal to a Value (SQL)
- GREATEST: Returning the Largest Value
- LEAST: Returning the Smallest Value
- LOG: Returning a Logarithm (SQL)
- EXP: Returning e Raised to a Power
- MOD: Returning the Remainder of a Division
- POWER: Raising a Value to a Power (SQL)
- SQRT: Returning a Square Root (SQL)

ABS: Returning an Absolute Value (SQL)

The ABS function returns the absolute value of a number.

Syntax: How to Return an Absolute Value

\[
\text{ABS}(\text{arg})
\]

where:

\[
\text{arg}
\]

Numeric

Is the input value.

This function returns the value as the same data type as the argument. For example, if the argument is an integer, the result will be also be an integer.
Example: Returning an Absolute Value

ABS returns the absolute value of a number. This example,

\[ \text{ABS}(-5.5) \]

returns 5.5.

CEIL: Returning the Smallest Integer Greater Than or Equal to a Value

CEIL returns the smallest integer value not less than the argument. CEILING is a synonym for CEIL.

Syntax: How to Return the Smallest Integer Greater Than or Equal to a Value

\[ \text{CEIL}(n) \]

where:

\[ n \]

Numeric or Alphanumeric

Is the value less than or equal to the returned integer. For exact-value numeric arguments, the return value has an exact-value numeric type. For alphanumeric or floating-point arguments, the return value has a floating-point type.

Example: Returning an Integer Greater Than or Equal to a Value

CEIL returns an integer greater than or equal to the argument.

\[ \text{CEIL}(N) \]

For \( N=1.23 \), the result is 2.

For \( N=-1.23 \), the result is -1.

FLOOR: Returning the Largest Integer Less Than or Equal to a Value (SQL)

FLOOR returns the largest integer value not greater than a value.

Syntax: How to Return the Largest Integer Less Than or Equal to a Value

\[ \text{FLOOR}(n) \]
where:

\( n \)

Numeric or Alphanumeric

Is the value greater than or equal to the returned integer. For exact-value numeric arguments, the return value has an exact-value numeric type. For alphanumeric or floating-point arguments, the return value has a floating-point type.

**Example: Returning an Integer Less Than or Equal to a Value**

FLOOR returns an integer less than or equal to the argument.

\[
\text{FLOOR}(N)
\]

For \( N=1.23 \), the result is 1.

For \( N=-1.23 \), the result is -2.

**GREATEST: Returning the Largest Value**

With two or more arguments, GREATEST returns the largest (maximum-valued) argument. The arguments are compared using the following rules:

- If any argument is NULL, the result is NULL. No comparison is needed.
- If the return value is used in an INTEGER context, or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a floating-point context, or all arguments are floating-point-valued, they are compared as floating-point values.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a character string, the arguments are compared as character strings. In all other cases, the arguments are compared as binary strings.

**Syntax:** How to Return the Largest Value

\[
\text{GREATEST}(value1, value2, \ldots, valuen)
\]

where:

\( value1, value2, \ldots, valuen \)

Numeric or alphanumeric

Are the values to be compared.
Example: Returning the Largest Value

GREATEST returns the largest argument.

\[
\text{GREATEST}(X, Y, Z)
\]

For \(X=2\), \(Y=0\), and \(Z=-1\), the result is 2.

For \(X='B'\), \(Y='A'\), and \(Z='C'\), the result is 'C'.

LEAST: Returning the Smallest Value

With two or more arguments, LEAST returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is NULL, the result is NULL. No comparison is needed.
- If the return value is used in an INTEGER context, or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a floating-point context, or all arguments are floating-point-valued, they are compared as floating-point values.
- If the arguments comprise a mix of numbers and strings, they are compared as numbers.
- If any argument is a character string, the arguments are compared as character strings. In all other cases, the arguments are compared as binary strings.

Syntax: How to Return the Smallest Value

\[
\text{LEAST}(\text{value1, value2}, \ldots, \text{valuen})
\]

where:

\[
\text{value1, value2}, \ldots, \text{valuen}
\]

Numeric or alphanumeric

Are the values to be compared.

Example: Returning the Smallest Value

LEAST returns the smallest argument.

\[
\text{LEAST}(X, Y, Z)
\]

For \(X=2\), \(Y=0\), and \(Z=-1\), the result is -1.

For \(X='B'\), \(Y='A'\), and \(Z='C'\), the result is 'A'.

406  Information Builders
LOG: Returning a Logarithm (SQL)

The LOG function returns the natural logarithm of the input value.

**Syntax:** How to Return a Logarithm

\[
\text{LOG}(\text{arg})
\]

where:

\[
\text{arg} \\
\text{Numeric} \\
\text{Is the input value.}
\]

This function returns double precision numbers with three decimal places.

**Example:** Returning a Logarithm

LOG returns the natural logarithm of a value. This example,

\[
\text{LOG}(4)
\]

returns 1.386.

EXP: Returning e Raised to a Power

The EXP function returns the mathematical constant e raised to a power.

**Syntax:** How to Return e Raised to a Power

\[
\text{EXP}(\text{arg})
\]

where:

\[
\text{arg} \\
\text{Numeric} \\
\text{Is the value of the power to which to raise the mathematical constant e.}
\]

**Example:** Returning e Raised to a Power

EXP returns the mathematical constant e to a power. This example,

\[
\text{EXP}(4)
\]

returns 54.598.
MOD: Returning the Remainder of a Division

The SQL function MOD returns the remainder of the first argument divided by the second argument.

Syntax: How to Return the Remainder of a Division

\[
\text{MOD}(n, m)
\]

where:

\(n\)

Numeric

Is the dividend (number to be divided).

\(m\)

Numeric

Is the divisor (number to divide by). If the divisor is zero (0), MOD returns NULL.

Example: Returning the Remainder of a Division

MOD returns the remainder of \(n\) divided by \(m\).

\[
\text{MOD}(N, M)
\]

For \(N=16\) and \(M=5\), the result is 1.

For \(N=34.5\) and \(M=3\), the result is 1.5.

POWER: Raising a Value to a Power (SQL)

The POWER function returns the value calculated by raising the first argument to the power specified by the second argument.

Syntax: How to Return a Value Raised to a Power

\[
\text{POWER}(arg1, arg2)
\]

where:

\(arg1\)

Numeric

Is the value to be raised to the power specified by \(arg2\).
**arg2**

Numeric

Is the value of the power to which to raise arg1.

**Example:** Returning a Value Raised to a Power

POWER returns the value calculated by raising the first argument to the value specified by the second argument. This example,

\[ \text{EXP}(2, 4) \]

returns 16.000.

**SQRT: Returning a Square Root (SQL)**

The SQRT function returns the square root of the input value.

**Syntax:** How to Return a Square Root

\[ \text{sqrt}(\text{arg}) \]

where:

**arg**

Numeric

Is the input value.

This function returns double precision numbers with three decimal places.

**Example:** Returning a Square Root

SQRT returns the square root of a value. This example,

\[ \text{SQRT}(4) \]

returns 2.000.
The SQL functions described in this chapter perform a variety of conversions, tests, and manipulations.

In this chapter:

- COUNTBY: Incrementing Column Values Row by Row
- DB_EXPR: Inserting an SQL Expression Into a Request (SQL)
- HEX: Converting to Hexadecimal
- IF: Testing a Condition
- LENGTH: Obtaining the Physical Length of a Data Item
- VALUE: Coalescing Data Values

**COUNTBY: Incrementing Column Values Row by Row**

The COUNTBY function produces a column whose values are incremented row by row by a specified amount.

**Syntax:**

`COUNTBY(arg)`

where:

- `arg`
  
  Integer
  
  Is the value that is incremented for each record.

This function returns an integer value.

**Example:**

Incrementing Column Values Row by Row

In the query,

```
SELECT COUNTBY(1), COUNTBY(2) FROM T
```
the first column takes on the values 1, 2, 3, ..., and the second column takes on the values 2, 4, 6, ...

**DB_EXPR: Inserting an SQL Expression Into a Request (SQL)**

The DB_EXPR function inserts a native SQL expression exactly as entered into the native SQL generated for a FOCUS or SQL language request.

The DB_EXPR function can be used in a DEFINE command, a DEFINE in a Master File, a WHERE clause, a FILTER FILE command, a filter in a Master File, or in an SQL statement. It can be used in a COMPUTE command if the request is an aggregate request (uses the SUM, WRITE, or ADD command) and has a single display command. The expression must return a single value.

**Syntax:**

How to Insert an SQL Expression Into a Request With DB_EXPR

\[
\text{DB_EXPR}(\text{native\_SQL\_expression})
\]

where:

\[\text{native\_SQL\_expression}\]

Is a partial native SQL string that is valid to insert into the SQL generated by the request. The SQL string must have double quotation marks (")) around each field reference, unless the function is used in a DEFINE with a WITH phrase.

**Reference:**

Usage Notes for the DB_EXPR Function

- The expression must return a single value.
- Any request that includes one or more DB_EXPR functions must be for a synonym that has a relational SUFFIX.
- Field references in the native SQL expression must be within the current synonym context.
- The native SQL expression must be coded inline. SQL read from a file is not supported.
**Example**: Inserting the DB2 BIGINT and CHAR Functions Into a TABLE Request

The following TABLE request against the WF_RETAIL data source uses the DB_EXPR function in the COMPUTE command to call two DB2 functions. It calls the BIGINT function to convert the squared revenue to a BIGINT data type, and then uses the CHAR function to convert that value to alphanumeric.

```
TABLE FILE WF_RETAIL
SUM REVENUE NOPRINT
AND COMPUTE BIGREV/A31 = DB_EXPR(CHAR(BIGINT("REVENUE" * "REVENUE")) ) ;
AS 'Alpha Square Revenue'
BY REGION
ON TABLE SET PAGE NOPAGE
END
```

The trace shows that the expression from the DB_EXPR function was inserted into the DB2 SELECT statement:

```
SELECT
T11."REGION",
SUM(T1."Revenue"),
((CHAR(BIGINT( SUM(T1."Revenue") * SUM(T1."Revenue") ) )))
FROM
wrd_fact_sales T1,
wrd_dim_customer T5,
wrd_dim_geography T11
WHERE
(T5."ID_CUSTOMER" = T1."ID_CUSTOMER") AND
(T11."ID_GEOGRAPHY" = T5."ID_GEOGRAPHY")
GROUP BY
T11."REGION"
ORDER BY
T11."REGION"
FOR FETCH ONLY;
END
```

**HEX: Converting to Hexadecimal**

The HEX function converts its input value to hexadecimal.

**Note**: This function is available only for DB2, Ingres, and Informix.

**Syntax**: How to Convert to Hexadecimal

```
HEX(character)
```

where:

```
character
```

Is the input value.
This function returns an alphanumeric value.

**Example: Converting a Value to Hex**

This example,

```
HEX('n')
```

returns 6E.

**IF: Testing a Condition**

The IF function tests a condition and returns a value based on whether the condition is true or false.

**Syntax: How to Test a Condition**

```
IF(test, val1, val2)
```

where:

- **test**
  - Condition
  - Is an SQL search condition, which evaluates to true or false.

- **val1, val2**
  - Are expressions of compatible types.

This function returns a value of the type of val1 and val2. If test is true, val1 is returned, otherwise val2 is returned.

**Example: Testing a Condition**

This example tests COUNTRY. If the value is ENGLAND, it returns LONDON. Otherwise, it returns PARIS.

```
IF(COUNTRY = 'ENGLAND', 'LONDON', 'PARIS') =
  'LONDON'   if COUNTRY is 'ENGLAND'
  'PARIS'    otherwise.
```

This example tests COUNTRY. If the value is ENGLAND, it returns LONDON. If the value is FRANCE, it returns PARIS. Otherwise, it returns ROME.
IF(COUNTRY = 'ENGLAND', 'LONDON',
    IF(COUNTRY = 'FRANCE', 'PARIS', 'ROME')) =
    'LONDON'  if COUNTRY is 'ENGLAND'
    'PARIS'    if COUNTRY = 'FRANCE'
    'ROME'     otherwise.

LENGTH: Obtaining the Physical Length of a Data Item

The LENGTH function returns the actual length in memory of a data item.

Syntax: How to Obtain the Physical Length of a Data Item

LENGTH(arg)

where:

arg

Any type

Is the length of the argument. It can be between 1 and 16 bytes.

This function returns an integer value.

Example: Obtaining the Physical Length of a Data Item

LENGTH returns the length in memory of a data item. This example,

LENGTH('abcdef')

returns 6.

This example,

LENGTH(3)

returns 4.

VALUE: Coalescing Data Values

Note: The SQL function VALUE is not supported. Instead, use the SQL operator COALESCE. For more information see COALESCE: Coalescing Data Values on page 419.
VALUE: Coalescing Data Values
SQL operators are used to evaluate expressions.

In this chapter:

- CASE: SQL Case Operator
- COALESCE: Coalescing Data Values
- NULLIF: NULLIF Operator

CASE: SQL Case Operator

The CASE operator allows a value to be computed depending on the values of expressions or the truth or falsity of conditions.

Syntax: How to Use the SQL Case Operator

In the first format below the value of test-expr is compared to value-expr-1, ..., value-expr-n in turn:

- If any of these match, the value of the result is the corresponding result-expr.
- If there are no matches and the ELSE clause is present, the result is else-expr.
- If there are no matches and the ELSE clause is not present, the result is NULL.

In the second format below the values of cond-1, ..., cond-n are evaluated in turn.

- If any of these are true, the value of the result is the corresponding result-expr.
- If no conditions are true and the ELSE clause is present, the result is else-expr.
- If no conditions are true and the ELSE clause is not present, the result is NULL.

Format 1

```
CASE test-expr
  WHEN value-expr-1 THEN result-expr-1
  . . .
  WHEN value-expr-n THEN result-expr-n
  [ ELSE else-expr ]
END
```
**Format 2**

```sql
CASE
    WHEN cond-1 THEN result-expr-1
    . . .
    WHEN cond-n THEN result-expr-n
    [ ELSE else-expr ]
END
```

where:

* `test-expr`  
  Any type  
  Is the value to be tested in Format 1.

* `value-expr1, ... , value-expr-n`  
  Any type of compatible with `test-expr`.  
  Are the values `test-expr` is tested against in Format 1.

* `result-expr1, ... , result-expr-n`  
  Any type  
  Are the values that become the result value if:
  - The corresponding `value-expr` matches `test-expr` (Format 1).
  - or
  - The corresponding `cond` is true (Format 2).

The result expressions must all have a compatible type.

* `cond-1, ..., cond-n`  
  Condition  
  Are conditions that are tested in Format 2.

* `else-expr`  
  Any type  
  Is the value of the result if no matches are found. Its type must be compatible with the result expressions.

This operator returns the compatible type of the result expressions.
Example: Using the SQL Case Operator

CASE COUNTRY
  WHEN 'ENGLAND' THEN 'LONDON'
  WHEN 'FRANCE' THEN 'PARIS'
  WHEN 'ITALY' THEN 'ROME'
  ELSE 'UNKNOWN'
END

returns LONDON when the value is ENGLAND, PARIS when the value is FRANCE, ROME when the value is ITALY, and UNKNOWN when there is no match.

COALESCE: Coalescing Data Values

The COALESCE operator can take 2 or more arguments. The first argument that is not NULL is returned. If all arguments are NULL, NULL is returned.

Syntax: How to Coalesce Data Values

COALESCE(arg1, arg2, [ ... argn ])

where:

arg1, arg2, ..., argn

Any type

Are data values. The types of the arguments must be compatible.

This operator returns the compatible type of the arguments.

Example: Coalescing Data Values

This example,

COALESCE('A', 'B')

return A.

This example,

COALESCE(NULL, 'B')

return B.

This example,

COALESCE(NULL, NULL)
return NULL.

**NULLIF: NULLIF Operator**

The NULLIF operator returns NULL if its two arguments are equal. Otherwise, the first argument is returned.

**Syntax:** How to Use the NULLIF Operator

NULLIF(arg1, arg2)

where:

arg1, arg2

Any type

Are data values. The types of the two arguments must be compatible.

This operator returns the compatible type of the arguments.

**Example:** Using the NULLIF Operator

NULLIF operator returns NULL if two values are equal. This example,

NULLIF(IDNUM, -1)

returns NULL if the identification number is -1, otherwise it returns the number.
